tal powers and strength of mind. The happiness was not reserved to him to survive those days of ecclesiastical domination, when a man (to use the language of Paley) might as well have put a rope around his neck as demonstrate against the abuses of established institutions. But his name remains to draw forth the sympathy which the memory of an old reformer excites. He instances, among the many illustrious French professors who, elevated by merit, under the influence of reform, retrieved the feeble character of the profession in France, the energetic and talented M. Corvisart. He more particularly adverts to the perfection at which Corvisart arrived in all his discriminations and prognostics relative to diseases of the heart and great bloodvessels. Corvisart constantly brought cases of the most grave and obscure nature before the pupils of *La Charité*, and, with his scalpel in his hand, ultimately verified those changes which he had predicted. M. Moreau, a contemporary, states, that so astonishing was Corvisart's accuracy in organic diseases of the heart, that two-thirds of the thirty patients in the clinical wards, were admitted upon his bare suspicion of the existence of those diseases; and circumstances proved that he was rarely mistaken in any one of them.

But sure I am, from my own limited experience as an humble country physician, that the discrimination of the precise nature of such cases and their complications, and of one disease of the heart from another, is rendered, in many points, not yet quite so easy as the drawing of a line between a kettle and a cartwheel. When I am not working abroad, I am generally studying pretty hard at home; and I can plainly see that practitioners often meet with cases that differ from those regular diseases of the circulating system which are classified by pathologists, and which rather tend to baffle practitioners than to display their discriminating powers, if we judge from their hints, admissions, hesitations, suppressions, and uncertain language, both on the continent and in this country. The difficulty occurs, in practice, in numbers of instances, which never appear in print, and for very good reasons. To look into the heart of man, and detect "the hell that's there," is proverbially difficult in morals, but to pronounce the nature of its fleshy maladies, is yet a harder task. For example: What a controversy has there been exhibited in this part of the kingdom between individuals (whom on both sides I know and esteem) who, on the one side, have insisted that *here* was organic disease of the heart, and on the other that there was *not*, in the case of Mr. Bennett, which gave rise to the trial against the Eagle Office at Worcester!* It

were well if no such controversies ever ensued to expose the fallibility of the profession. When it is admitted that we cannot distinguish between organic diseases and palpitations, in all cases, by the stethoscope alone (*Dr. Mackintosh*),—that hypertrophy occurs where there is no impulse, which is its pathognomic sign, and that impulse has occurred when there was no hypertrophy,—that a plethoric state of the heart may produce the same signs as hypertrophy,—that pericarditis, in particular cases, may be confounded with dilatation (*Andral*), that time and repeated investigations only can decide whether there exists functional or organic disease of the heart,—when these things are borne in mind, the positive opinion, that organic disease does exist, cannot be made with too much deliberation. On the other hand, knowing that few men die from organic disease of the heart alone, but from morbid action supervening on morbid structure (*Professor Macartney*),—that palpitations and hypertrophy are only manifested at intervals (*Andral*),—that simple palpitations, and those palpitations which are symptomatic of organic lesions, are liable to intermissions (*Easton*),—and that active organic diseases of the heart are generally suspended for a time, to relapse suddenly and terminate fatally (*Professor Home*),—an equal degree of caution is needful in denying the existence of organic disease, upon a single examination instituted for the purpose of filling up an assurance-office certificate. The advantage may be fairly presumed to rest with the parties who had the most opportunities of investigation.

I am going to introduce to notice a few cases of disease of the heart. The two first are not uncommon, but serve, notwithstanding, to illustrate, in many points, the two last, which are more obscure, and therefore more instructive. Many fields of pathology have been so thoroughly mowed as not to present a blade of grass, but this region not so utterly barren. "Where a fact is never exactly like the facts already observed, it is necessary, if I may so speak, to individualize without cessation. In this consists all the art of diagnosis, and it is for this reason that the instructed man who has seen most, is also he who ought to see best." (*Andral*.) Aware of the great difficulty of discrimination in heart cases,—of the double and exceptional import of the discriminating signs, whether those signs be communicated by symptoms or sounds,—I submit every point rather by way of query than affirmation, and with the greatest diffidence to the profession. I quote solely the authorities of professors and hospital practitioners (most of whom I have heard) on account of their superior experience, and insert their names in parentheses for the sake of avoiding "he says," and "says he," and "he remarks," and "he observes," and the like.

* *Extracts from the late Mr. Bennett versus the Eagle Office, Worcester.*

CASE 1.—*Pulmonary Tubercles, with Dilation of the Right Auricle, and Symptoms of Hypertrophy of the Left Ventricle.*

Mr. Henry Bellamy, of the Priory Farm, Goodrich, *at. 21*, was affected April 27, 1833, with cough, and expectoration of roundly-formed *crachats*, which had followed the influenza. The cough was attended with symptomatic fever, and was of importance, because it had occurred before, in conjunction with palpitations, and hemorrhage from the lungs in considerable quantities. After that occurrence his respiration and general powers were always feeble. He took calomel, opium, and James's powder, with an ammoniacum mixture, and after all fever and symptoms of increased action were removed, the Polygola mixture of the French, with Compound Tr. Benz. and Tr. Mar. Ferri. The cough was greatly relieved, and the respiration improved, and he had expectorated only a single clot of blood since the first attack. But excessive nocturnal perspiration came on, which wetted through the bed-clothes. These were restrained, at first, to two nights in the week, and they were gradually prevented altogether by superacetate of lead, with hyoscyamus, mineral acids in his drink, and citric acid with opium; but he still continued to get thinner. By the 26th of May, the cough and expectoration had ceased; he had recovered his general strength considerably, and had rather gained flesh, and he found the seat of irritation not so deep in the chest, but more at "the top of the wind-pipe." His chest was stimulated externally with tartar emetic, and the polygola was continued, with tartar emetic, ipecacuan., &c., which he never took "without relief to the cough, acting as if it went immediately to the part affected." In June all chest symptoms were removed, except slight cough, and occasional light-sweats, but the debility, the shortness of breath, and the emaciation, continued the same. The citric acid, with opium, and extract of myrrh, again removed the sweats, and procured him refreshing sleep and easy expectoration, which had always been attended with violent straining of the lungs in the morning.

He continued to get better until the beginning of October, when he was seized with palpitation, to which he had been subject, at times, for years, previously to the attacks of hæmoptoe, and pain in the left thorax, extending from the bottom of the sternum, towards the spine, and occupying the space of a span. This pain, which was more or less constant, came on in an exasperated degree by stitches, and when he exercised his lungs in motion and on horse-back. The cough was frequent, and expectoration was considerable, but there was no pain on respiration. The respiration was audible at both sides of the chest, but less

so ~~at the top~~ ^{at the bottom} of the lobes, and it was much ~~more~~ ^{more} ~~honorous~~ ^{honorous}, ~~distinct~~ ^{distinct}, and puerile at the ~~base~~ ^{base} than elsewhere; the flapping of the valves of the heart was very clear. I gave him the American remedy for consumption, Tr. Digitalis and Guaiac., with Vin. Colchici, and inserted a seton for the palpitations.

On the 25th October, the palpitation and fever were removed, the former having been greatly benefited by the seton, which he kept in for some time afterwards, but the pulse and general strength were much depressed, and the expectoration was too abundant, for which he resumed the Opium and Citric Acid, with the Polygola and Tr. Lyttæ. He now lay easiest on the affected side, but when he lay on his right side, he had violent stitches, which stopped his respiration, and set him gasping. In foggy mornings he was much worse. He got better again, and enjoyed a considerable period of convalescence, but his lungs continued weak.

Twelve months afterwards (20th Nov.) he was affected with such extreme shortness and hurry of expiration and inspiration, and oppression in the chest, that he could not walk the smallest distance without exhaustion. He had been free from this state until three days before, when a north-easter set in, and he had cough with thick expectoration in the morning, but without pain; wheezing occurred in the night, with inability to lie on the *left* side. He had occasional circular tightness of the chest, girdling him in at the sternum; less emaciation than three years ago, and swelling of the legs.

But one of the principal symptoms was the very forcible action of the heart. This thumping of the heart came on most violently, with cold extremities, on lying down in bed at night, and shook the bed furniture. He was always purplish in the face, and in his youth he had been apt to turn of a blue or a violet hue in the extremities and face, from any chill of the feet, or from bathing in the Wye. The jugular quivered sometimes at night during increased impulse, but there was no constant turgescence. When sitting quietly and leaning forwards, the breathing was easy, the voice strong, and the action of the heart not felt. When he walked, the respiration was short, and stopped almost entirely. He was sometimes relieved in this state, by tears, for he was subject to a sort of nervous attack, like male hysteria. Much disordered nervous action, to which the whole family are subject, was blended with the organic disease. The impulse was so great at the bottom of the sternum, that it shook my head at the end of the tube, and those of four young farmers, who were present. The heart of the left ventricle was below the level of the standard, and the pulse

pressible, and the respirations were audible under the right scapula. The crepitting r  le and bubbling r  le were heard under the left clavicle, and the mucous r  le was audible to himself in the trachea. At the space between the left scapula and vertebra, pectoriloquy was very distinct, but it was much more jarring, loud, and distinct, over the right scapula. The voice, however, was naturally resonant. The respiration was clear everywhere, but blowy and sonorous.

I now offered an opinion that the right ventricle was hypertrophied, and, from the sound, as well as the impulse, in concurrence with long-standing symptoms, that there was dilatation of the right heart. The history of the case favoured the opinion of organic disease. The grandfather had died of angina pectoris from ossification of the coronary arteries, and was examined by the late Mr. Paytherus and Dr. Jenner, hence deriving, I believe, the first fact on which Dr. Jenner founded the incorrect doctrine afterwards promulgated by Dr. Parry, that angina was generally caused by ossification of the nutritious vessels of the heart. His father was affected with palpitation and cough, and was conspicuous for venous fulness and purple tendency of skin, combined with a nervous and hypochondriacal temperament. One sister is now suffering from irritable heart, with symptoms partly nervous and partly indicative of accumulation of blood in the cavities; another is subject to sudden deadness and purpling of the skin, from slow circulation in the veins of the arms.

I gave it as my judgment, that as he was affected with hæmoptysis so long as eight years ago,—that as he had been subject to it and violent action of the heart, more or less, with weak and short respiration, for the last four years, and had improved in flesh and strength whenever the heart became more subdued,—that as the symptoms might arise from chronic bronchitis,—and that as dithisis rarely takes more than one year to run through its course,—the pectoriloquy might chance to proceed not from tubercular excavations but bronchial dilatation. At the same time I could not but entertain serious doubts and apprehensions.

Nov. 24. I put him on a diet of biscuit, ice, milk, and slops, and under the action of nitromy, internally and externally, which answered considerably the action of the heart. It produced too much syncope in the first instance. He was ordered to refrain from whatever would hurry the respiration or irritation, but so soon as an amendment took place, he rode to Monmouth Fair, and was seized with such a fit of dyspnoea, and inordinate palpitation, that he hurried to his aunt's, threw himself into a chair, and lay on his arm on a table with his chest exposed. He was somewhat recovered. He died shortly after his return, and was lying under great op-

pression of breathing; his pulse not strong; his respirations 40 in a minute, carried on by the shoulders and muscles of the chest and abdomen; the body in perpetual agitation; the lips and nostrils empurpled; the mucous r  le in the larynx, and extending from the right clavicle down the right chest. Leeches, blisters, sedatives, and antispasmodics, were all useless, except that the leeches smoothed the way to the grave by relieving the dyspnoea. It was strange how he would sink, like an hysterical woman, into a semispasmodic state of breathing, and then rally again, and be as easy in a sitting posture as in good health. The r  le extended from the right lobes to the bottom of the left and upwards, and after frequent sinkings and reactions he expired on Monday, Dec. 2, at 2 o'clock. On the preceding evening he called up every farm servant, and gave to every man the character for his services which he deserved, pointed out what alterations he intended to have made upon the farm, and discoursed deliberately with his family on their several affairs. I remember a female in phthisis, who sent for me to see her die, conversing of it as of taking a journey, until nearly her last breath. There is a philosophy in deaths like these, which may be owing partly to temperament but greatly also to integrity of conduct, and to a nature free from the malignant passions.

Post-mortem Examination.—Mr. Thompson, a gentleman of skill, and surgeon to the Ross Dispensary, examined the thorax with me. The right auricle was twice the size of the left, but though dilated it was not thickened. The columnar corners were very strong, and well defined. The right ventricle was not dilated or thickened. There was much fat about the heart. The primitive vessels were not obstructed. The lungs were firmly bound by old adhesions to the posterior parietes of the chest. The root of the lungs on the right side was more purple and soft than on the other. They were considerably occupied with gray tubercles and small conical. Much congestion existed whereabouts they were thickest. There were two cavities, one on each side of the spine; that on the right side was nearest to the posterior wall of the chest, which may account for the greater loudness of the voice from that point. There was no particular appearance in the bronchial tubes or membrane, except a frothy oozing from the smaller tubes.

Remarks.—The most singular circumstance in this case, is the fact that there was every symptom of hypertrophy of the right ventricle, but no other organic affection than simple dilatation of the right auricle; but it will be more in order to notice in the first place the origin of the disease. I cannot reflect upon the circumstances shewing a tendency to palpitations and heart

affections in the family of the patient, and upon the early manifestations about the heart in his own case, without seeing in the case something like a predisposition. M. Rostan says he has opened a thousand individuals with hypertrophies of the parietes of the heart, and has never known a case of hypertrophy or of aneurysm, that is, active dilatation of the heart, which arose, in a primitive manner, from an hereditary or acquired disposition, but that he has found invariably an obstacle to the course of the blood, and that hypertrophy without obstacle, is merely exceptional, and barely possible. The present case was certainly not one of dilatation by predisposition alone, without obstacle, for the phthisis itself was the obstacle, but I infer disposition, from the history of the case, and I cannot conceive how, if the heart be not influenced by original tendency to disease, the same obstacle should so often occur without that organ being affected. The experienced and acute professor of *La Salpêtrière* says, that the obstacle, and not the hypertrophy, is the disease. Wherein is the obstacle in those cases of hypertrophy by congestion, which, according to M. Andral, arise from increased assimilating powers of the part, and a greater deposition of atoms than are absorbed into the circulating medium? That consummate pathologist moreover has given a case of dilatation of the right ventricle, and hypertrophy of its parietes, without obstacle to the auriculo-ventricular orifice, or any other lesion, after inflammation of the pericardium and bronchial membrane,* and a similar case of simple hypertrophy of left ventricle, after latent pericarditis without obstacle. Wherein, again, is the obstacle in those cases of dilatation which arise from congenital disproportion of the two parts of the heart,—according to M. Laennec, the “most frequent cause” of dilatation? Mr. Henry Cline was of opinion that the heart grew under diseases, which rendered it liable to congestion,—and that the greater quantity of blood pouring through it in those who are in the habit of taking violent exercise, had a tendency to increase its size,† an opinion considerably strengthened by the frequency of diseases of the heart in our labourers in this part of the country. Dr. Parry also thought that there was a connection between dilatation, and accumulation of blood in the heart, aorta, and right pipe. Others think that the heart may hypertrophise, like the pugilist's or blacksmith's deltoid, from increased exercise merely.

Occasional palpitations were the earliest symptom in this case. Authority and observation point out three kinds of palpitation; simple nervous, simple plethoric, and

symptomatic. All pathologists admit the nervous and symptomatic, but few, among whom are Rostan, Andral, Martinet, and Drs. Parry and Macintosh, admit the plethoric and congestive. For my part, I think that the first two, and sometimes all three, are blundered (but more on this head in an express paper), and I think that the nervous and congestive were united in this case; or, in full, that original nervous irritability of the heart was combined with a liability to undue accumulation of venous blood in the right cavities, particularly on the contraction of the vessels upon the surface of the body. The symptoms and proofs of a nervous temperament in this case,—the coming on of the palpitations at night in the greatest degree,—and the fact, as we are told, that all palpitations not arising from organic but functional disease of the heart, more frequently affect the auricles than the ventricles, and the right auricle more than the left,*—stamped the nervous character upon them. But though the occurrence at night is said to be characteristic of nervous palpitation (M. Laennec and Dr. Macintosh), the increase of action and of impulse of the right ventricle upon the contraction of the surface circulation, and the crowding in of the blood into the right cavities, upon all occasions of chill, gave to the case also the mixed congestive character. As there was an obstacle in the lungs, so were they in measure symptomatic. It may happen, generally speaking, that nervous palpitations are usually worst at night, but I have known palpitations, arising from hypertrophy also, greater at night than in the day, but not attended with interruption of rest, as in the case of simple nervous palpitation. In addition to palpitation, the patient was next affected with hæmoptysis, and subsequent cough. Hæmoptysis is a well-known effect of congestion of the lungs produced by palpitation, dilatation, or hypertrophy of the right side of the heart, and is most frequent when caused by hypertrophy of the right ventricle. The affection consists generally in what MM. Corvisart and Laennec term pulmonary apoplexy by congestion and hæmorrhage from the bronchial membrane, or, as some pathologists state, by transudation and exhalation from the minute bronchial capillaries. (Andral.)

The nature of the case indicated dilatation, for the augmentation of the heart's volume, in complication with phthisis, consists most generally in dilatation of the right cavities, with or without hypertrophy of the parietes, and seems to depend on the obstacle experienced by the blood in traversing freely the vascular structure of the lungs, which is often, to a certain extent, obliterated. Induration of the pulmonary substance, stricture, obstruction, or

* Clinique Médicale, tom. 3, p. 531.

† MS. Notes of Lectures by J. F.

* Professor Homs. MS. Notes of Lectures.

of the pulmonary artery or vessels of the interior of the lungs, or a too straight aorta, may each produce dilatation by disturbing the circulation in the lungs. When the affection of the heart is slight, symptoms, but little marked, announce it during life, and auscultation may at most but recognise its existence; when more considerable, the symptoms may be more characteristic. (*Andral*.)

Auscultation is peculiarly fallible in these complications, for in a certain number of cases, the great extent of the beats of the heart does not indicate a morbid state of that organ, as they result uniformly from induration of the pulmonary structure, in which they may be extended with force under one or other clavicle, and it may be, in some individuals, even to the back. (*Andral*.)

The progress of the case also indicated dilatation. The palpitations were at first moderate, and occurred at longer intervals, with oppressed breathing and tubercular irritation, but were on the whole slow; at last both the palpitation and dyspnoea became more formidable, and assumed towards the close the character of asphyxia. It seemed to me that through the more irritable state of the right side of the heart than of the left, and its undue action, more blood was hurried, in consequence, by the pulmonary artery into the lungs, than could be received and circulated at an equal rate by the left heart. Palpitation and dyspnoea may be manifested a long time, without any material change in the thickness of the heart's parietes, or in the caliber of its cavities; but there is a continual tendency to that change till it is effectuated, and all the causes, moral or physical, which produce any difficulty whatsoever in the circulation, singularly hasten the production of dilatation. But whilst the palpitations are absent, the application of the hand or ear to the precordial region, will not discover anything unusual in the heart, and so long as there is no aneurysm, the pulse also will be natural. (*Andral*.)—All these phenomena strictly accorded with the progress of the case given.

The violet circulation, with disturbed respiration, formed a third indication of dilatation. Swelling of the face and violet discoloration of the lips, impossibility of horizontal decubitus, irregularities and intermissions of pulse, are so many symptoms that coincide with pulmonary phthisis, but do not depend on it. They announce an aneurysmatic state of the central organ of the circulation, that is, an augmentation of its volume. With many phthisicals we have observed such a suffocation, that they were obliged to keep themselves sitting up in their beds, unable to breathe more freely, and less so the more which overwhelmed them, the more they tried. Wherever we have ob-

served these symptoms, the existence of a disease of the heart, and, in particular, of dilatation of the right cavities, has accounted for it. (*Andral*.)

The jugular turgescence during the more violent attacks of dyspnoea and palpitation, presented a fourth sign of dilatation of the heart and pulmonary congestion. The livid or violet tint, as in asphyxiated persons, which occurs in people with very troubled respiration, and in dilatation of the heart, is the effect of a want of equilibrium between the quantity of air entering the air-cells, and the quantity of blood to be vivified. If more blood than in the normal state is accumulated in the pulmonary vessels, a greater quantity of air is necessary in a given time, and consequently there is a sensation of oppression, and a drawing together of the inspiratory movements, which shows the introduction of an excess of air, and the opposition of some cause to the free passage of blood through the pulmonary vessels, preceding, therefore, any other sign of the existence of organic disease of the heart. In a further stage, all efforts are insufficient to modify the whole of the blood accumulated in the lungs. The blood, already changed, can no longer pass freely into the left cavities of the heart, whence reflux and stagnation, and a new obstacle to the pulmonary blood in the right auricle, great venous trunks, and parenchymatous tissues. When the veins bring back, more or less directly, the blood towards the heart, there occurs the greatest difficulty of respiration, then increased asphyxia, and then, notwithstanding, the air enters freely into the vesicles, the feeling of suffocation, from the quantity of inspired air not being in proportion to the mass of blood.

But these symptoms are not unequivocal proofs of dilatation. Stasis of blood in the left auricle and lungs, dyspnoea, cough, previous hæmoptoe, and violet discoloration of the lips, face, and skin in general; stasis in the right ventricle and auricle of the same side, and all the venous system; are part of the leading symptoms, towards the end of an hypertrophy, arising from an obstacle of the aortic valves or thoracic aorta, before or after the giving off of the subclavian. (*M. Rostan*.) Besides, one of Laennec's tests of hypertrophy of the left ventricle is jugular turgescence. (*Dr. Macintosh*.) Dilatation may also be confounded with particular cases of pericarditis. There are certain forms of inflammation of the pericardium which influence the movements of the heart in such manner that a disturbance of the circulation results from it, giving rise to the same phenomena as those observed at a certain period of aneurysm of the heart. (*M. Andral*.) This authority gives a case of latent pericarditis, in which there came on, all of a sudden, extreme dyspnoea, increasing in intensity till it produced death by as-

phyxia. The p.-m. appearances were, serous effusion into the pericardium, and simple hypertrophy of the left ventricle of the heart, without obstacle, which had been marked but by slight impulse. He gives another case of pulmonary phthisis, in which the patient was seized suddenly with troubled respiration,—accelerated respiratory movements,—which were attributed to intercurrent pneumonia. The oppression and dyspnoea became more considerable, and all the symptoms of consumption were complicated with those of aneurysm of the heart; the face was puffed, the eyelids were a little infiltrated, and the lips were swollen and violet. The left ventricle was slightly hypertrophied; but the real disease turned out to be pericarditis, without pain. He very reasonably thinks that the aneurysm did not exist, merely because it could not have been formed all of a sudden. Some similar phenomena characterize one or two other of his cases of obscure pericarditis without pain.

All these signs that “palter with us in a double sense” exhibit the great dubiousness of heart cases, and prove the necessity of weighing every individual symptom, and the whole history of a case; and then taking time for the further lifting up of the veil, before we presume to give a conclusive pathological opinion.

The peculiar circumstance in this case was the presence of the signs of hypertrophy, without its existence. We are told that the principal symptoms of an hypertrophy of the right ventricle are, “a shock near the inferior part of the sternum, and none less at the left, the general circulation little changed, and some phenomena of pulmonary congestion.” (*M. Rostan.*) I know that the shock, or “thumping,” as Mr. Abernethy used to term it, against the sternum, in this case, could not come of simple dilatation; for though dilatation renders the patient more liable to sudden attacks of palpitation and dyspnoea than hypertrophy (*Dr. Macintosh*), the palpitations are attended, not with increased, but diminished impulse, with purple countenance and swollen jugulars. (*M. Martinet.*) I do not know that I ever saw or read of a case of simple dilatation in which the pulsation of the heart was not more feeble and more extended, except a case given by M. Andral, in which the contractions of the heart were more sensible at the inferior part of the sternum than at any other part, with a particular bruit: the only lesion was an enormous dilatation of the right auricle, with slight hypertrophy of its parietes. I also know that M. Laennec and others have considered that this shock, or impulse, cannot arise from simple palpitations, and that it is the distinguishing symptom of hypertrophy. Knowing these things, and that dilatation at all events existed, I could not conceive how that dilata-

tion could co-exist with increased impulse of the heart, unless it were combined with hypertrophy: but though hypertrophy was evinced by this its sign, dilatation only was discovered *post mortem*, and the violence of the impulse was owing to mere palpitation. How is this explained? I presume,—that the dilatation was of long standing, but that the increased motion and increased force of the right ventricle were produced by the temporary condition of the circulation of that side of the heart and of the lungs;—that the tendency to hypertrophy, produced by obstructed circulation, had not existed long enough to superadd the change of structure to the change of action, as happens in some cases in which the symptoms of dilatation occur without its existence;—that it had not existed long enough to produce the internal hypertrophy which will sometimes ensue in phthisis, notwithstanding the tendency of the heart in that disease to participate in the general diminution of the muscles of animal life and the general atrophy (*M. Andral*):—that, as aggrandisement of the heart's substance may exist without aggrandisement of its action, or, that, as mere thickening of the heart will not produce impulse without increased contractile energy of its fibres, particularly in old persons and those whose circulation is slow, so increased impulse may arise from an increased volume of blood and increased activity in the cavities of the heart, without increased nutrition of its substance;—and, lastly, that impulsion, as is admitted by M. Andral, Dr. Macintosh, and others, may be produced by mere palpitation in a violent degree, and cannot consequently be set down as an unequivocal and unconditional symptom of hypertrophy. Should we not then always shape our opinions subject to these important exceptions and conditions, in equivocal cases?

There are two circumstances in connection with this subject that ought to be borne in mind. One is, that organic affections of the heart, accompanying chronic bronchitis with considerable oppression, may be consecutive as well as primitive, and that organic disease of the heart may produce chronic bronchitis, and, by congestion and distention, hemorrhage of the mucous membrane, and those mucous-serous accumulations in the air passages and vessels which increase the dyspnoea, augment the pulmonary congestion, and set the affection of the heart on the quick march. (*Andral.*) The next circumstance is, that common symptomatic palpitations occur in pneumonia, phthisis, accidental formations in the lungs, or in the tract of the great vessels, as in all other maladies, near or remote, which produce an obstacle to the circulation. (*M. Rostan.*) I think they often arise in phthisis from a contiguous irritation, and flatulency concurrent with the phthisis, and they bring on tightness and constriction of the

sternum, and increase the irritation of stomach.

The case of James Dean, 48, at Ross, was an example of their coincidence with accidental formations. About four years ago, after an attack of hæmoptoe and cough, preceded by palpitations so violent that they shook the watch that hung over the bed, and compelled him to tie a shawl round his waist to prevent the impulse, he coughed up a solid earthy concretion as big as a nutmeg, which, he says, is now in the possession of Dr. Thomas Evans of Gloucester. He has been under my care for dyspnoea, evidently connected with fulness of blood in the right side of the heart and chest, consequent on engorgement of the liver, which is a frequent precursor of such affections. "Palpitations are known by the absence of the signs that accompany diseases of the heart," says M. Rostan. They are so in these cases, but not in such a case as I have given, nor in many others.

The diagnosis of pulmonary tubercles was as obscure in this case as the precise condition of the heart; they were probable from many symptoms; from the readiness of the lungs to become irritated to such a degree as to bring on coughing; the *long continuance of the cough after the attack of hæmoptoe, and the persisting debility and wasting of flesh*. But there was no dull sound on percussion, no absence of respiration in one spot or another, though it was certainly blowy and sonorous, which is said to indicate crude tubercles, surrounded by healthy structure; nor was there the weakness of murmur which generally occurs in the second stage of phthisis; the complexion was purple; the peaked and white face of consumption never made its appearance; the night sweats were common to himself and others of the family, from having irritable and nervous constitutions; besides those sweats, marasmus, and short and frequent breathing, are as common to chronic bronchitis as to phthisis; the catarrh of phthisis, which resembles ordinary bronchitis till the tubercles become so numerous as to create a new set of symptoms (*Laennec*), marked the real disease. The pectoriloquy discovered towards the close, at a point where resonance only was perceptible, about a year or more before, rendered the diagnosis more unequivocal. We have cases of bronchitis mistaken for pulmonary consumption, the only difference being the louder respiration and resonance of the voice. (*Dr. Macintosh*.) It is difficult to say whether the occasional pains of the chest were owing to muscular affection, or depended on the formation of tubercles in the lungs; but in the latter stage of phthisis they frequently proceed from pleuritic inflammation, and cause those *small cavities to be formed which are almost constantly found near a cavern when situated in the surface of the lungs*. This case

came under my care in Dec. 1833, and died in 1834, and I fear I shall have another such case in Thomas Jones, ætat. 35, who has had hæmoptoe, with disease of the mucous membrane of the alimentary tube. These are cases, says the celebrated teacher in the school of medicine, in the true spirit of medical experience and clear-sighted induction from facts, in which phthisis makes its *début* very obscurely, in which the appearance of the first symptoms always succeeds a simple bronchitis, hæmoptoe, or peripneumonia. Some present pneumonic, others bronchitic symptoms, but when convalescent they never recover their general powers, nor their *en-bon-point*, and they continue to cough. The diagnosis of tubercles is obscure, because the cough, the only local symptom which exists about the chest, does not suffice to characterize them, and the absence of strength, and the persistence of the leanness, are looked upon as connected with the antecedent malady.

If this state continues for ever so little, it should inspire a strong suspicion of organic lesion, and if the cough does not cease, the development of pulmonary tubercles is to be apprehended. It suffices to say that this cough ought not to be neglected, and the cure, as is too often the case, ought not to be abandoned to nature. Many dread the employment of active antiphlogistic treatment, because, say they, the subject is enfeebled and exhausted. But this feebleness, this exhaustion, depends, above all, upon the serious change which is forming in the lungs, and it is only by combating this change that you can restore some strength to the patient. "An actual convalescence is almost never accompanied with this prolonged state of feebleness, and the rapidity with which strength and flesh return in individuals who have been kept a long time on severe regimen, provided no organ continues diseased in them, is a thing truly remarkable." (*Andral*.)

A moderate number of tubercles will excite sufficient constitutional irritation to destroy one patient, while another will live out the destruction of one lung. But I do not think the tubercles were so much the immediate cause of death as the oppression of the circulation and respiration in the right heart and lungs. M. Andral advocates decisive emissions of blood, when pulmonary congestion and oppression ensue from dilatation; but, in other places, he demonstrates that cases of dilatation do not bear blood-letting well, and require a tonic treatment. It is condemned by every other leading authority, except under particular emergency. In this case, the patient had suffered a so deadly kind of debility, after being bled for attacks of dyspnoea and oppression, under previous hands to mine, that he had an instinctive horror of the practice, and would not submit to it. He was placed between two fires

and bleeding could only add to the debility of one or other disease, either of which was sufficient, and one sure, to destroy him. He might have lived longer, had he been shut up in one room, in an artificial and equal temperature, and compelled to perfect repose of body and mind. But his active disposition rejected this plan, and by hurrying the circulation through the cavities of the heart and the bronchial structure of the lungs, he no doubt brought on the last and fatal attack. Exercise, in disease of the heart, will bring on severe dyspnoea and a feeling of suffocation, but, on the other hand, all affections of the lungs, which give rise to long-continued and severe dyspnoea, and habitually short and difficult respiration, and a feeling of oppression, may occasion palpitations and affections of the heart; and all causes, that upset the balance of the circulation, and produce an overflow of blood about the heart, may excite this class of affections. (*Dr. Mocintosh.*)

I have reported this case, and reasoned on the symptoms at length, for one such case is a representation of a whole family, and supersedes the necessity of another of the kind. Such cases are not unfrequent, and a knowledge of them is very useful to the practitioner.

Ross, Nov. 14, 1835.

ON THE TREATMENT OF PULMONARY CONSUMPTION

BY THE
INUNCTION OF LARD.

To the Editor of THE LANCET.

SIR,—During the last fifteen months I have experimented upon the effects to be produced on cases of phthisis, by administering nourishment through the skin, and with very evident success.

My practice consists in simply causing the patient to rub in for half an hour every day upon the chest, back, and ribs, or on any other large surface, as much lard as can be absorbed in that time. In very advanced cases, this operation is repeated as often as three times a day. At the same time any urgent symptoms are combatted with the ordinary remedies.

The effect of this treatment is, I find, to stimulate the nutritive functions of the body, increasing rapidly the patient's strength; to quiet the action of the heart, to allay pain of the chest, and to remove difficulty of breathing. These effects are made apparent in fifteen or twenty days, and even earlier.

Out of four very severe cases of phthisis which have been submitted to my care, two

in which there existed also the most evident signs of dyspepsia, of nine months' standing, have been completely cured. A third case, catarrhal, with tubercles, remains yet in doubt. The fourth, tuberculous, and complicated with dilatation of the cavities of the heart, a case of two years' standing, is progressively and evidently improving. In the third of the above cases, the patient, a female, was weighed on the 15th of October, when her weight, including clothes, was found to be 83 lbs. She then commenced rubbing in the lard, and on being weighed on the 10th of November, she had gained seven pounds, and this increase of weight she has maintained up to the present date (November 21), weighing on the morning of each day, 87 or 88 pounds, and at night invariably 90.

A friend of mine, also a medical practitioner, has likewise made trial of my plan of treatment, upon what, in his opinion, was a hopeless case, of nineteen months' standing. The cough and expectoration have now nearly subsided under it, and the breathing and strength are restored. I am promised a detailed account of this case, which I hope to transmit to you, in a short time, as also that of other cases now under treatment; and whatever may be their result, whether they terminate in perfect or partial convalescence, that result shall be faithfully recorded.

My immediate object in giving this hasty notice at the present time, is to invite those of my medical brethren who have hospitals under their care, to aid me in my experiments, by giving the treatment a trial. Any professional communications bearing upon this subject, sent to me free from expense, whether in favour of or against the plan, would be esteemed an obligation; as upon a subject of so much importance, and leading to so much general benefit, it is very desirable to accumulate a body of facts, verified by the observation of others. Cases not far advanced have certainly appeared to yield with the greatest readiness to this remedy. But to the profession generally, I look to confirm or destroy my hopes of having discovered something in the shape of a remedy for this reproach to medical science. The plan has this advantage, that it may be combined with any other mode of treatment the practitioner wishes to employ.

What other forms of disease this power of stimulating the nutritive functions, through the absorbent surfaces, is capable of combatting, every practitioner's experience will point out to him. For my own part, my experiments lead me also to think, that it exerts a marked control over scrofulous action.

In conclusion I may state, that what induced me to try the inunction of lard, in consumptive cases, was the fact, and the health generally enjoyed by those who

constant occasion to handle flesh, combined with the acknowledged fact, that butchers and their families are remarkably exempt from that disease. I remain, Sir, yours faithfully,

EDGAR ASHE SPILSBURY, M.R.C.S.
Walsall, Staffordshire, Dec. 7, 1835.

TRIAL OF CREOSOTE

IN SPASMODIC AFFECTION OF THE STOMACH WITH VOMITING.

To the Editor of THE LANCET.

SIR,—The following case, illustrative of the non-efficacy of creosote in allaying spasmodic or neuralgic pain of the stomach and vomiting (without inflammation of that organ), is transmitted for insertion in your very able Journal, by, Sir, your most obedient servant,

JOHN WALKER, M.D.
353, Argyle-street, Glasgow.

In the 9th number of *THE LANCET*, at pages 275 and 276, Dr. Elliotson relates one case of neuralgic pain of the stomach, and two of severe vomiting, so successfully treated with creosote, that in one of the latter cases it was only necessary to exhibit the medicine once; and in the other the administration of a few doses checked the vomiting, which had continued for some time, producing its usual effects of debility, &c. From the very high esteem with which Dr. Elliotson regards this medicine, I was inclined to try it in the following case:—

Case.—A.B., ætat. 22, an unmarried female. Has for the last three years complained of acute pain along the whole spinal column, greatly increased on motion or pressure, and accompanied by two lateral curvatures, describing, in all, the letter *s*, and including all the dorsal and lumbar vertebrae. There is no paraplegia; the uterus, bowels, urinary organs, &c., perform their functions regularly; the skin generally feels natural, and there is always some degree of appetite. Among the numerous symptoms under which this patient labours, the most distressing is constant vomiting of all ingesta, of whatever temperature or kind, and generally from two to twenty minutes after they have been taken. This vomiting of food is attended with considerable pain; but frequently violent retching takes place when no food has been taken, and which is attended by violent spasmodic pain of stomach, generally continuing from twelve to twenty-four hours after the retching has ceased.

As every justifiable means had already been resorted to for the alleviation of the spinal pain (which in this case arises from mere relaxation of the ligaments &c.)

without the slightest benefit, and the vomiting being not only the most troublesome symptom, but precluding all possibility of improving the general health, and as nothing had hitherto tended in the slightest degree to check it, I felt inclined to try the creosote. It was, therefore, given according to Dr. Elliotson's plan, in doses of two drops in mucilage and water every six hours, but without effect. Next day it was increased to four drops, and in this quantity the first dose produced headache, and increased the vomiting and pain of stomach. The same quantity was again exhibited at the end of six hours, which only aggravated the former symptoms, and a short time after the administration of the third dose the headache became agonizing; countenance flushed, with great heat of surface; retching and pain of stomach very severe. It also acted powerfully upon the bowels, producing six watery stools the first hour, with severe griping, likewise inducing painful micturition, and imparting to the urine a strong creosotic odour.

The medicine was now intermitted for twenty-four hours, and again commenced in the same doses, but in combination with twenty drops of solution of mur. of morphia, when the symptoms induced were as violent as formerly, with the exception of the diarrhœa. Being still inclined to give the medicine a fair trial, it was again omitted for twelve hours, and afterwards exhibited when neither vomiting nor pain of stomach was present, and in doses of only one drop every six hours. The second dose produced violent and immediate vomiting, with severe pain of stomach.

Now as Dr. Elliotson says, "This was a case merely of spasmodic or neuralgic pain of the stomach, not constant, but occurring at intervals. It was not increased by pressure or hot ingesta." There was no pain after taking food, but merely a sensation of uneasiness until the offending aliment had been rejected, thereby leading me to suppose that there was no inflammation of the stomach, and inducing me to try the creosote, from Dr. Elliotson's representation of its beneficial effects in such cases. I found it not only failed to allay the vomiting and pain of stomach when present, but actually in small doses inducing them when they did not previously exist, and also producing other symptoms, which, in this case, would alone have induced me to lay it aside.

Many will at once exclaim that in this case, the vomiting arose from the affection of the spinal column and nerves, and I do not deny but they in part did stand in the relation of cause and effect; but as the spinal irritation and pain were subject to frequent and severe exacerbations, which did not at all affect the vomiting, and as the retching was frequently worse when the back was comparatively easy, we are quite

justifiable in concluding that the vomiting depended upon other and more latent causes for its continuance during the lengthened period of three years. I am inclined to suppose (particularly as there is no appearance of organic affection of the stomach) that the irritation of the spinal nerves was, in the first instance, the cause of vomiting, and afterwards, that irritation being partly subdued, but the stomach still being accustomed to be relieved of its uneasy sensations by regurgitation, constantly recurred to this method, requiring for its suppression moral and physical efforts more powerful than this patient seemed capable of exerting.

At the same time that this case illustrates the length of time which a person may live, with only occasionally retaining a small portion of food, it clearly proves that creosote, like all other remedies, will fail in checking vomiting and pain of stomach without inflammation.

PURULENT URETHRAL DISCHARGES IN CHILDREN.

To the Editor of THE LANCET.

SIR,—You will probably think the following cases of sufficient interest to obtain a place for them in your Journal. I am, Sir, yours respectfully,

WILLIAM MOSS.

Windsor, Dec. 5, 1835.

I was requested last month to see a little girl, three years of age, residing in Eton, whom I found suffering under every symptom of gonorrhoea. She had swollen and inflamed labia, a thick purulent discharge from the vagina, and acute pain in passing the urine. On making inquiry, I ascertained that the eldest sister, who was eleven years old, had, in the preceding June, been affected in the same manner; and that the second sister (eight years old) had also, a few weeks afterwards, been in precisely the same state: the mother had neglected to obtain advice for them, as she fancied that the symptoms arose only from weakness, and the discharge therefore had continued on them in a slight degree up to that time. Two days after this visit I was desired to look at the grandmother, a woman aged sixty-six years, living in the same house, who was afflicted with one of the most frightful attacks of purulent ophthalmia that I ever beheld. About three days afterwards, the brother (aged six years) of the girls was affected with swelling and inflammation of the prepuce and glans penis, accompanied by a profuse discharge and pain in passing his urine, which symptoms continued to be very severe for some days. I had seen several cases of inflamed prepuce in children,

from what I considered want of cleanliness and I had seen five cases of gonorrhoea in little girls, from the same cause at least. I could trace the disease to no other, but I had never seen cases so decidedly marked, and of so infectious a nature, as the present.

There is no reason to suppose that these children had been infected from any venereal source, but it is probable that gonorrhoea may be generated in the genitals of the human female without any intercourse of the sexes, and, as I believe, without the communication of any specific virus. The parents of these children are very industrious, and, for their station in life, very respectable people. I have attended both at different times for several years; the mother acts as a laundry woman for a most respectable family in this town, where her husband has long lived as butler, always sleeping in the house; the mother has had no vaginal discharge or uterine affection. The eldest and youngest child have slept constantly with her for a long period. The other two children sleep by themselves. They have all been washed and dried with the same towels. The grandmother has had leucorrhoea upon her for many years, which has been suspended during the ophthalmia. She has had the use, I am told, of a towel exclusively to herself. Having simply stated these facts, I leave others to draw from them their own conclusions.

CÆSAREAN OPERATION,

PRACTISED WITH SUCCESS, BOTH FOR THE MOTHER AND THE CHILD.

By Professor STOLTZ, of Strasbourg.

JEANNETTE LIALE, twenty-six years of age, has been affected with rachitis since her infancy. At the age of ten she suffered from a severe attack, accompanied by convulsions, and followed by paralysis of the tongue. Since that period her growth has been completely arrested. She now measures only forty-four inches; from the summit of the coccyx twenty-six inches from the latter to the heels eighteen. Her head is very large, and disproportionate to the rest of the body; the spinal column is quite straight, and the chest well formed; the pelvis, though well formed, is very small; the limbs are curved.

This girl menstruated at the age of seven-teen. On the 12th of November, 1834, she presented herself at the hospital of Strasbourg, being eight months gone with child. An examination was immediately made, and the vagina found to be short and narrow. The antero-posterior diameter of the pelvis measured with the finger and Wundt's pelvimeter, gave two inches, four lines and

Fundus uteri ascended to the epigastrium, and the movements of the child announced that it was strong and healthy.

It resulted from this examination that the women could not be delivered at term, without the aid of a dangerous operation. In the night of the 19th of December the patient was seized with pains in the loins and desire to urinate; labour-pains soon set in, and mucus tinged with blood was discharged per vaginam. The toucher showed that the neck of the uterus was effaced; its orifice was directed backwards and to the left side; the child's head, pretty large, was felt behind and above the pubis. At three o'clock p.m. the pains became more severe; the os uteri was now directed towards the centre of the pelvis, and very much dilated; the membranes became tense at each pain; the head occupied the same position.

Before deciding on the measures to be adopted, Messrs. Erhmann and Stoltz (the author of the paper) wished to introduce the whole hand into the vagina, in order to explore the pelvis with more care. The narrowness of the parts, however, did not permit the introduction of more than four fingers. The impossibility of a natural delivery being now evident, and all other means being judged insufficient, the cesarean operation was decided upon; the woman consented, and on an exploration being made for the last time, it was found that the os uteri was dilated nearly to the size of a crown piece; the membranes intact; and that the head of the child, having glided off the pubes, occupied the inlet, but a very small portion of the cranium projected into the cavity of the pelvis. The child was still alive.

Operation.—The patient being placed horizontally, and everything prepared in the usual manner, M. Stoltz having ascertained that no portion of intestine lay between the uterus and abdominal wall, made an incision along the linea alba, commencing two inches and a half above the symphysis pubis, and extending two inches and a half above the umbilicus, which lay at the left side. The fascia transversalis and peritoneum being thus exposed, the operator seized them with a pair of common forceps, near the centre of the wound, and made an oblique opening, which gave issue to a little serosity; a concave probe-pointed bistoury was now introduced through the orifice made, and the peritoneum divided upwards and downwards along the whole extent of the original incision. In spite of the attention given to keep the abdominal parietes closely applied upon the uterus, a small portion of the intestine protruded at the lower angle but was easily reduced. In order to assure himself whether the uterus had rotated upon its axis, M. Stoltz slipped his hand into the upper angle of the wound, and

having ascertained that this was not the case, he immediately commenced incising the anterior wall of the uterus, slowly and by layers; the uterus here was about five lines thick; the last layer ruptured and exposed the membranes; the opening into the uterus was now enlarged, by gliding the index finger between the organ and its contents, and conducting a bistoury on the finger; before rupturing the membranes every care was taken to prevent the passage of the liquor amnii into the cavity of the abdomen. On opening them, from three to four ounces of water came away, and the fœtus was immediately extracted by the feet.

The child, a female, began at once to cry; was strong and vigorous; eighteen inches long; weight five pounds and three quarters. The vacuum which now followed the uterine contractions rendered protrusion of the intestines, and effusion of blood, &c., into the abdominal cavity, imminent; these accidents, however, were fortunately avoided, and some minutes allowed to pass before the extraction of the placenta; this being done, the uterus retreated at once into the pelvis a portion of small intestine at the same time protruding at the lower angle of the wound; this was easily restored, but in reducing it, a portion of epiploon became engaged in the upper angle, though here the wound was carefully compressed by a sponge. The epiploon was in turn reduced, but this being done with the fingers a little roughly, gave rise to such violent contraction of the diaphragm, with hiccup, as to threaten at every minute the expulsion of the whole content of the abdomen; the hiccup gave way, however, on the assistant's acting more gently and the edges of the wound were now brought together exactly, by four points of suture: strips of sticking-plaster, two inches broad and three feet long, were passed round the body and crossed over the wound and the whole was retained by bandages. The operation lasted from twenty-five to thirty minutes.

The accidents which declared themselves immediately after the operation, were long and stormy, and for a considerable time gave rise to the greatest inquietude; they are described most minutely, hour by hour day by day, by the author; but as they consisted in the means generally employed for combatting irritation and inflammation, we do not think it necessary to reproduce them here. On the thirty-second day after the operation the patient left her bed for the first time, during an hour; on the thirty-fifth the wound was completely cicatrized and on the 70th the menstrual discharge reappeared. The child, which continued to enjoy good health, was given to a nurse.—(*French Gaz. Med.*, Nov. 21.)

Memoirs of the Royal Academy of Medicine, Paris. Fasciculus 1, 1836.

We have just received the first Number for the approaching year of the Memoirs of the Royal Academy, but we fear the following enumeration of its contents will prove that the Committee of Publication have not been very happy in the selection of materials. The memoirs selected are,—

1. A Notice of the Plague of Moscow in 1771. By M. GERARDIN.
2. A Memoir by Dr. GOYRAUD ON

INGUINO-INTERSTITIAL HERNIA.

Under this name the author describes a species of hernia, long known as "incomplete hernia," but never studied with precision. The viscera pass out from the abdomen through the superior orifice of the inguinal canal, or through an abnormal opening in the fascia transversalis, and instead of traversing the canal, to appear at its external ring, they become lodged in the canal itself, which they dilate, and in the neighbouring interstices of the abdominal parietes. Inguino-interstitial hernia, then, has its seat in the inguinal canal. When voluminous, it may extend towards the spines of the ileum, separating the inferior fasciculi of the small oblique or transverse muscles, from the fascia transversalis; it has two complete membranous coverings, viz., the sac and a prolongation of the fascia transversalis. The cavity in which it is lodged is formed anteriorly by the aponeurosis of the great oblique muscle, and the inferior fasciculi of the small oblique; posteriorly by the fascia transversalis; inferiorly by the reflected edge of Poupart's ligament, from which the fascia transversalis arises, and above by the lower edge of the transversalis muscle and a few fibres of the small oblique.

The cavity containing the hernia has two orifices; the one communicating with the abdomen is the internal ring; the external ring forms the external orifice; the neck of the sac is embraced by the abdominal orifice of this cavity. In old hernia, its external (?) surface adheres strongly to the edges of the ring. The folds of the peritoneum have contracted adhesions together, and hence arises a well-marked thickening of the neck of the sac, which presents internally the appearance of a defined ring. The hernia

may tend towards a prolongation through the inguinal ring, and thus be formed of two parts, one contained in the inguinal canal and the neighbouring part of the abdominal wall; the other situate in front of the inguinal ring, or even in the scrotum. Mr. Lawrence describes a case of this latter kind. Finally, it may happen that the testicle is arrested in its passage through the inguinal canal, the serous envelope continuing to communicate with the peritoneal cavity. A portion of intestine may become engaged in this sac, and thus form a true congenital hernia in the inguinal canal. Of this rare case the author gives an example in his second observation.

The third memoir selected, is on the effects of corrosive sublimate in the preservation of wood, and on the effects of this substance on the health of sailors. By M. KERAUDREN.

The 4th memoir is entitled, "Observations on the Cure of Wounds without Inflammation. By JAMES MACARTNEY, M.D." These consist of a few insignificant remarks on the eternal subject of water-dressing. It is to be regretted that principles which in themselves are sound, and worthy of being made known to our Parisian brethren, were not developed in a more complete manner than we find them in the two and a half pages, of which Dr. Macartney's memoir consists. We have heard the University of Dublin called "The silent Sister," and from the present specimen, we might suppose that she had only just begun to speak. What a pity that we cannot apply to her the text, "Out of the mouths of babes and sucklings" shall come forth—wisdom!

5. NEW EXPERIMENTAL RESEARCHES IN TRAUMATIC HEMORRHAGE.

This paper is by M. AMUSSAT, whose researches have been principally directed to ascertain the nature of the changes which take place between the skin and the vessel, when an artery has been opened, and the bleeding has been arrested either spontaneously or otherwise.

When we remove the skin, we find the tumour formed by the effused blood of a uniform red colour, and enveloped in a kind of sac of cellular tissue. The small wound in the artery is distinct. A small isolated coagulum indicates the point it occupies. If we cut horizontally the blood

of half of the tumour, we find an homogeneous layer of coagulated blood; a circular point, more or less large, of a lilacish-brown colour, and filled with a red clot, indicates the traject of the wound. This clot may be easily removed by a forceps, and then we find a kind of canal, which always follows the direction of the wound, and leads to the injured point of the artery. These results differ from those obtained by Jones and Beclard, probably because they dissected the artery before wounding it.

M. Amussat concludes, from the experiments which he has made on a great number of animals:—

1st. That in closing the external opening into the skin, we close the canal of new formation by which the hemorrhage has taken place.

2nd. It results from the discovery of the central canal through the centre of the sanguinous tumour, that by following it we are conducted in a certain manner down upon the injured point of the artery.

3rd. That a mammelonated coagulum, of a deep or nearly black colour, indicates surely the orifice of the wounded artery.

6. BICETRE IN 1792.—ABOLITION OF IRONS IN THE TREATMENT OF THE INSANE.

This is a fragment from the unpublished works of Pinel by M. SCRIPION PINEL. It is a very curious document, and is worthy of attention in more than one point of view. We reproduce it nearly literally:—

Towards the latter end of 1792, while the storm of revolutionary fury was raging in the centre of Paris, a scene of far different character took place at the gates of the city. For the first time the irons, under which the unfortunate inhabitants of Bicêtre had hitherto groaned, were removed, and a system of humanity substituted for the regime of severity and torture that had so long prevailed in the hospital of insane. It was at this period that a man, relying on his knowledge and experience, and stimulated by the honourable desire of benefiting humanity, revolted against the idea of chaining up the wretched creatures entrusted to his care, like so many wild beasts in a dungeon. Indignant at this stupid outrage to human nature, he addressed himself to the authorities of the city. The answer was unfavourable. Pinel was treated as an aristocrat and a moderate—terms at that time almost equivalent to a mandate of death. But Pinel was not easily arrested in his pursuit of good; he presented himself before the corporation of magistrates, and with an eloquence commendable to the noble object of his pursuit, demanded the reformation of such irrational

and monstrous treatment. "Citizen," said one of the members present, "I will visit thee to-morrow at Bicêtre; woe be on thee if, amidst the deranged, thou concealest a single enemy of the people."

Couthon arrived on the following day at Bicêtre. The appearance of the man was almost as strange as that of any of the deranged he came to visit. Deprived of the use of his lower limbs, and constantly carried about in the arms of a domestic, he looked like a fraction of humanity planted upon another frame, from the top of which, with a soft and feminine voice, he dealt out the impitiable sentence of death. Couthon came to see the patients himself, and visited them one after another. He was conducted to their quarter, but in the midst of cries and ferocious threats, interrupted only by the rattling of chains in some solitary dungeon, the republican was received with such a clamour of insults that he was soon compelled to retire in disgust. He turned towards Pinel and said, "Citizen, thou art mad also in desiring to unchain such ungovernable animals." "Citizen," answered Pinel, "I have a profound conviction that the unfortunate wretches before us are merely untractable because they are deprived of air and liberty, and I have every reliance on means of a more humane nature."

Complete master of his own actions, Pinel now immediately commenced the exertion of his desire; but it was impossible to conceal the real difficulties of the task he had undertaken. To liberate more than fifty furious madmen without compromising the safety of his other more tranquil patients, was an experiment too hazardous; he determined, therefore, on beginning with twelve. The only precaution he thought it necessary to take was to preserve twelve strong waistcoats, in case they should become altogether unmanageable.

The first to whom Pinel addressed himself was the patriarch of the house, the oldest inhabitant of this den of misery,—an English captain, whose history is unknown to all the rest, who had remained in the same cell, chained up, for forty-five years. He is regarded as the most dangerous of all the prisoners; his guardians approach him with the greatest circumspection, for once, with a single blow of his manacles, he laid a domestic dead on the spot. Since then he has been ironed with more precaution; but this increased rigour has only exasperated his temper, naturally furious. Pinel entered the cell, alone and calm. "Captain," said he to the unfortunate, "if I remove your chains, and restore you to liberty, will you promise me to be reasonable and not injure your neighbours?" "Certainly," was the reply; "but you jest; they are too much afraid, and so also are you." "No," said Pinel, "I am not afraid, for I have six men behind me to execute my orders; but trust

my word; be confident and docile; I will give you liberty at once if you will merely put on this linen jacket instead of these heavy tormenting chains."

The captain submits quietly to all the preparations, shrugging his shoulders without articulating a word. In a few minutes his irons were removed, and he was left alone in his cell, the door of which, for the first time, was wide open. Several times the unfortunate man rises up and falls again on the ground; the confinement of nearly fifty years in a sitting posture has nearly deprived him of the use of his limbs: at length, after a quarter of an hour spent in useless efforts, he succeeded in sustaining himself upright, and, with a faltering step, advances from the bottom of his dungeon towards the door. His first movement is to look up to the heavens: he cries out with an ecstasy of joy, "Oh, how beautiful!" During the whole day he is constantly in motion, running up stairs and descending immediately afterwards; the same expression constantly on his lips, "Oh, how beautiful! how comfortable!" Towards evening he enters quietly into his cell; sleeps on a better bed, expressly prepared for him. During a lapse of two years more, spent at *Bicêtre*, he even becomes useful in the establishment, exercising a certain degree of authority over the other patients, who willingly submit themselves to his orders. His companion in captivity is almost equally worthy of compassion; an old French officer who has been confined in irons for thirty-six years, during which he laboured under one of those terrible delusions so common in our days. Endowed with a feeble intelligence, and easily seduced by fanatical impressions, he had conceived, in his severe and mystic meditations, that God had chosen him for "the baptism of blood;" that is to say, "for the duty of killing his Christian brethren on this earth, in order to send them more speedily to enjoy the pleasures eternally reserved for the select of God." This burlesque idea gave rise to an atrocious crime. He commenced his homicidal mission by plunging a knife into the heart of one of his own children. Declared mad by a court of justice, and conducted to *Bicêtre*, he was tormented by the same frantic delirium for a long series of years. At length came calm, but without reason. He is now dull and silent; a fleshless spectre seated on a stone; his emaciated limbs are still loaded with the same chains which he formerly bore, and which he is now unable to sustain; they were left on, perhaps, as much through forgetfulness as with a desire to punish the cruel actions which brought him to the house of the mad. For him there was no hope of amelioration. Pinel had him transported into one of the beds of the infirmary. His legs are so stiff and contracted that he is unable even to extend them. However,

his agony is prolonged for a few months, and he died without being capable of feeling his deliverance.

The third presents a striking contrast. He is a man in the flower of his age; his eyes are sparkling, his language is elevated, and his manners are dramatic. In his youth he was a man of letters. Endowed with a sweet and gay temper, and a brilliant imagination, he spun many a web of love and honour, which he transferred to his impassioned romances. He wrote without ceasing; and in order to bestow more time on his literary occupations, he at length shut himself up completely in his chamber, passing often the day without food and the night without sleep. In this state an unfortunate passion intervened to exalt his ideas still further, and finish what a too vivid imagination had already commenced. He became desperately in love with a young girl in the neighbourhood, good and virtuous, as they are all, in the beginning, but who soon became fatigued of the unhappy author. She was faithless, and did not even leave the consolation which might arise from a doubt. During a year his soul was a prey to bitter concentrated grief; when suddenly struck with the ridicule of weeping for one so unworthy of his love, he passed from one extremity to another, and gave himself up, without bounds, to every excess. It was in the midst of one of these orgies that reason broke down; and, conducted to *Bicêtre* in a state of furious mania, he was thrown, about twelve years ago, into his dungeon, where he still vainly endeavours to rend asunder the irons that bind him down.

This patient was rather turbulent than dangerous; unable to comprehend the good he was about to receive, nothing but force compelled him to leave his chains; once liberated, he commenced running in a circle round the court, until he fell exhausted and breathless to the ground; the care of Pinel, and the fostering attention which he bestowed on this patient in particular, soon brought back his reason; but unfortunately he must return to the bosom of society, at that time so agitated; the event was not long doubtful; he cast himself into political agitations with all the ardour of his youthful passion, and on the eighth Thermidor his head fell upon the scaffold.

Pinel now enters the fourth cell; it is that of Chevigné, whose release from captivity is perhaps the most memorable fact of this remarkable day. Chevigné was a soldier in the French guards, and had only a single fault, that of being too much addicted to drunkenness: once elevated by wine he became quarrelsome, violent, and was the more dangerous, that his strength was prodigious. He was dismissed from his corps for repeated excesses, and having soon dissipated his feeble resources, became plunged

into a state of shame and poverty, which soon overcame reason. In his madness he thought himself a general officer, and would strike every one that did not immediately recognise his rank. It was at the termination of one of these quarrels, that he was brought to Bicêtre in the most furious state of excitement; there he remained ironed for ten years more carefully so than his companions, as he had more than once broken his chains by the simple force of his arms; once, it is said, having procured a few minutes liberty, he defied all the guardians united together to replace him in his cell, before he had made them pass under his leg; and actually performed this inconceivable feat upon eight men who attempted to make themselves master of his person; from that day his strength became a proverb at Bicêtre.

Pinel had already discovered in this man the germ of a good disposition, concealed beneath an excitement which was constantly kept up by the cruel treatment he was submitted to. He promised to ameliorate his condition in a short time, and these few words of comfort at once rendered him more calm. Pinel announced to him the joyful news that he was about to leave his irons. "To prove that I have confidence in you," said he, "and regard you as one born to do good, you shall lend your assistance in delivering these unfortunate creatures, who have not their reason as you have, and if you conduct yours. If as I expect and hope, I will take you into my own service, and promise to protect you for the rest of your life."

Never was a more sudden or complete revolution seen in the human intellect. The guardians themselves are seized with astonishment and respect at the example of Chevigné. His chains are yet scarcely removed from his limbs, and behold him careful, respectful, following with an attentive eye all the movements of Pinel, and executing his orders with promptitude and address. Behold him pouring forth words of peace, consolation, and reason, to his unfortunate fellow sufferers;—he, who a few minutes back was sunk below their level, but now stands before them elevated by the proud consciousness of liberty. This man, whose chains had demoralized during the fiercest portion of his manhood, and who, doubtless, would have dragged along the whole course of his existence in this fearful agony of intellectual suffering, this man becomes henceforward a model of good conduct and gratitude; more than once, in the most dangerous storms of the revolution, he saved the life of his protector; on one occasion, particularly, he rescued him from the hands of a band of malefactors, who were carrying him to the lamp* as an elector of

89. During the period of famine he leaves Bicêtre every morning, and returns with an abundant supply of provisions which gold could not purchase at that moment of universal want; in a word, his whole life is a series of acts of devotion to his liberator.

Chevigné is more than a grand and sublime lesson for the science; he is a conquest made to humanity of an honest and faithful mind from the infamous barbarity under which it had given way.

Next to Chevigné, in the neighbouring cell, are three unfortunate Prussian soldiers, chained there for a long series of years; no one knows the motive in which such rigorous treatment has originated; they are commonly inoffensive and calm, becoming animated from time to time in a language which nobody understands. The moment they perceive round them any strange assemblage of persons or things, they imagine themselves the object of hostile intentions, and oppose the removal of their irons with the utmost violence; when freed, they are unwilling to quit their prison, and remain fixed in the position to which they have been so long accustomed. The sentiment of liberty, so cherished by everything human, seems totally extinct in the bosom of these unhappy strangers.

[What a lesson in some of these facts!]

Die Erscheinungen und Gesetze des Organischen, LEBENS VON GOTTFRIED RIENHOLD TREVIRANUS. 2 B. (The Phenomena and Laws of Organic Life, &c.)

The Biology of Treviranus was commenced thirty-five years before the publication of the present work; and volume after volume slowly appeared, unfolding the fruits of persevering research, of continued experiments, and of genius such as has rarely been engaged in studying life. The productions of the human intellect, in their development, — unlike the growth of trees, where the operation of every successive year makes natural additions to each part, and helps to carry out the perfect idea of their form, — do not constitute the permanent materials of ultimate maturity; for the mind in its progressive investigation of phenomena, after endless essays, and innumerable observations, at last discovers one point of view, before which all former conceptions are rendered imperfect, and are at once broken up and superseded. In the process of generalization, the last principle includes the former, as one serpent swallows up another, that serpent being itself swallowed by a later and a mightier. Hence, Treviranus found

* During the revolution, it was a common practice to hang traitors on the cross-arms of the lamp — hence the cry of "à la lanterne."

that the investigations which he made in the progress of his own work, as well as the discoveries of others, rendered changes necessary in the early volumes, before the last were begun. This consideration led him at last to abandon the attempt to complete the "Biology," which is instinct with genius, and, so far as it extends, is the most comprehensive, scientific, and profound investigation of vital phenomena, which has been published since the days of Aristotle. In the present two volumes he has presented the entire circle of physiological laws and their phenomena in a compressed form;—

"The Biology," he remarks, "contains the history of the distribution of organic beings, and of the revolutions of living nature. I have excluded this from the present work, because it would have extended too far if all the obscurities of these questions had been critically examined, and because in this department I had no personal observations to add. Besides, the sun which was with me in the morning, when I went to my earlier work, now hastens to its setting. It is not the time for me to fix, as the aim of my labours, a too distant goal."

Byron, in an address to Goethe, while eulogizing the genius of the Germans, declares that nothing but the difficulty of pronouncing some of their names could debar them from immortality. Certain it is that the difficulties of acquiring a knowledge of their language has prevented many of their best works from becoming known to us, and shut out from this country some of their brightest thoughts. If the Physiology of Blumenbach had not been written in Latin, and if the work of Tiedemann had not been first translated into French, we might have remained ignorant of those valuable works unto this day. It is not, therefore, astonishing that the profession in this kingdom should not only hold the "Biology" of Treviranus in less esteem than it deserves, but should hardly know of its existence.

With what enthusiasm Treviranus has devoted his time to the study of life the introduction will show:—

"If," he exclaims, "the study of nature generally is one of the noblest occupations of man, the subject of our investigations especially deserves the attention of every educated person. To know himself, is the sage's first law. But no man can know himself,—can know either his mind or his body,—who does not compare himself with kindred beings. For ourselves, only single parts are susceptible of thorough investi-

gation. The rest are hidden. To penetrate into these, we must examine them in beings, where they lie bared to the eye."

Treviranus is evidently one of those men who think that nothing can be more pitiable than the observance of that severity of language which some practical writers desire to maintain by avoiding all expressions of feeling, and cautiously excluding all indulgence in the power of the imagination, not only in the formation of their style, but in their modes of thinking. None are too exact, though a few may be too cold. By referring to the Greek writers, to Bacon, and to Cuvier, it may be seen that nature is not exposed to view only in the form of anatomical preparations. Simply to analyze is to leave our work imperfect. The machine may be advantageously taken to pieces; but to perceive its operations the parts must be re-joined, when the contemplation of its evolutions will often excite the philosopher to renewed efforts, and may usefully imbue him with a highly poetic feeling. The volumes of Treviranus combine a mathematical accuracy of reasoning, with the finest sense of what is animating in philosophy. But to proceed with our translation:—

"He who devotes himself in a proper spirit to the study of living nature, is thereby elevated and ennobled, preserved from one-sidedness,* and restrained alike from superstition and unbelief. What is the earth, with all its treasures, for the great mass of mankind, but a stage filled with forms without any earnest signification? They pass before their eyes without touching the inward sense. They speak, but man is insensible to their voice, and understands not their language. He dies in abundance, sighing over the emptiness of existence and the monotony of day. The student and lover of nature is in a world ever presenting him with fresh views, which would never let him grow weary though he lived through centuries. All in it has for him a signification. He is no where a stranger, and no part of the earth is for him without charms, since he ever meets with nature. So did Stetter, enraptured with the study of the sciences, feel as happy in the desert Kamschatka as in a Paradise. He wished himself banished to Siberia, in order to quench his thirst for discovery.

"Such a spiritual life in the bosom of nature, cannot but nourish and sharpen the sense of truth and simplicity. Therefore was the natural philosopher J. August

* "Einsseitigkeit" has been translated into English before. "Prejudice," or "one-sidedness," does not exactly express the German idea.

Abraham Goetze, a preacher of peace, while his brother, the poet Melchior, raved against every independent thinker. An old poet says, 'He who makes verses, thinks only on them, not on lying and deceit.' This may be true. But it is not the same, to think of no unworthy things because the attention is withdrawn by other objects, or because the moral sense is elevated by constant occupation on noble subjects. There can be no great poet, but there are many superficial natural philosophers, without nobility of thought. Yet he who attains to the heights of Parnassus, was already a great man ere he climbed. He who is not made morally better by the study of nature, has not been impelled thereto by an inward tendency and constraint. This does not hold of the study of living nature only, but of that more emphatically. A man may possess profound knowledge in mineralogy, chemistry, and physics, without reflecting on the great questions, what and whence are we ourselves? Whither go we? But he can never arrive at any certainty as to the origin of the infusoria without stumbling on principles connected with those questions. Furthermore, no science is more intimately connected with other sciences than the science of life, therefore no one is less likely to fall into narrow-mindedness, than he who seeks to fathom this in all its parts. Vision, with all its various modifications in the various animals, can only be completely comprehended by him who is a proficient in optics, nor hearing without a profound knowledge of acoustics. The explanation of the processes of respiration, digestion, nutrition, and the development of animal heat, rests on chemical grounds. The doctrine of the geographical distribution of plants and animals, is strictly connected with physical geography and meteorology, as is the history of the former changes of living nature, with geology and archaeology. And he who is master of these and many more collateral sciences, cannot proceed far in the knowledge of life unless he be a philosopher.

"In every living thing there may be recognised a forming and working of every single part for all the rest, and for the whole; also proximately for the species, and for other species. This design is only possessed by the living. Yet it betrays itself in the smallest of these, only by the magnifying-glass of perceptible parts. In all external movements of animals, and even of many plants, there is likewise an appearance of voluntary, and on the other hand, of necessary destination to action. We find this combination of freedom and necessity, especially in the exercise of the instincts of animals. All observations of that design, and of this apparent spontaneity in endlessly various modifications, and all reflection thereupon, lead inevitably to an original reason, which can only be divine, and is no more a subject of speculation."

What follows is somewhat obscure, yet it will be received with respect from the lips of one who has devoted a long life to the study of physiology; who has been a fearless champion of truth; who never wrote a Bridgewater Treatise; and who would never sing a hired hymn even to the Creator:—

"Therefore," says this enthusiastic man, "were all who have investigated the phenomena of nature, men of deep religious feeling. I will only recal to memory Swammerdam, Bonnet, and Linnaeus. Their piety indeed wore the costume of their education and their age. But if Swammerdam appears doating in the theological applications which he made of his great zootomical discoveries, and worthy of pity when sitting at the feet of Bourignona, gloomy enthusiast: if Bonnet and many other naturalists of the last century, mistook their own wisdom for that of the Creator, they nevertheless sought, although mistakenly, that higher light whose reflection they had caught. He who fails to recognise this light in nature, sees unconsolable nothing in it, but an eternal circle of rising and setting. He who in dreams, or in poetry, seeks words which answer to the light, finds not truth but a phantasm of his own brain. But to him who enters on the right paths by the study of living nature, its muse herself will be a conductress, who remains true when all abandon him; and like Leucothea to the shipwrecked, will reach a holy veil when the waves of destiny threaten to swallow him up."

The whole of this introduction sounds rather like the solemn chorus to a Greek drama, than the opening of a work on physiology, where the scene is the world, over which human beings and other living forms, interwoven like the Hours, move in endless procession, while their nature and relations are declared by one whose lips had been "touched with living coal from the altar."

The division of the animal kingdom, adopted by Treviranus, deserves attention.

"According to my view," he says, "there are two great divisions of the animal kingdom; the one consists in animals that possess a real spinal marrow enclosed in a vertebral column, which is wanting in the other class. In the first, the entire brain always lies over the mouth, enclosed in a proper bony covering, the skull. In the last there is always a ring round the mouth, formed either of one brainlike mass, or of several knots connected by nervous filaments; the brain-like substance lies partly over, partly under the last; it has no special, bony, or horny capsule by which it is separated from the other internal parts of the head, and no

(See page 437, column 1.)

Results of the Original Researches of Treviranus.

process goes from the posterior part, which can be compared with the spinal marrow of the preceding animals. This agrees with Lamarck's division into vertebrate and invertebrate animals. They may be denominated animals with skulls, and animals without skulls.

"In all vertebrate animals, the anterior portion of the spinal marrow enclosed in the skull—the medulla oblongata—is of the same form as in man, and, in comparison with the brain, diminishes from man to the lowest degrees of this series of animals, in mass and in volume. According to the numerical differences of this relation, four classes of these animals may be distinguished. I found the limits of the relative weight of the medulla oblongata and the brain, to be,—

In the 1st Class between	1 : 85.0 and 1 : 6.5
2nd ditto	1 : 24.3 and 1 : 6.7
3rd ditto	1 : 3.6 and 1 : 3.2
4th ditto	1 : 3.5 and 1 : 1.0

"On the other hand the lower animals possess, by virtue of their vital tenacity, the power, already mentioned, of absorbing more oxygen, from a given amount of atmospheric air in which they are enclosed, than the higher animals, who die long before they have consumed the same amount of oxygen. The energy of their respiration is, at the same time, entirely dependent on the temperature of the medium in which they exist."

"The relation of the greatest diameter of the medulla oblongata, to the greatest diameter of the brain, extends,

In the 1st Class from	1 : 6.85 to 1 : 1.20
2nd ditto	1 : 4.45 to 1 : 1.12
3rd ditto	1 : 2.55 to 1 : 1.35
4th ditto	1 : 1.43 to 1 : 1.28

The first class embraces mammalia, including man; the second, birds; the third, amphibious animals; and the fourth, fishes.

The table at page 156 presents the results of his own, and of all other researches, on the respiration of animals, calculated on the supposition that the English is to the Parisian inch, as 0.938 to 1; that the temperature of the inspired air is 71°; the barometer at 30 inches; and oxygen in the atmosphere = 21; carbonic acid = 1 per cent.

Treviranus gives a new, and certainly the only accurate method, for determining the proportional force of respiration in animals. He observes,—

"We have yet no experiments by which it can be determined, if, in the various stages of vegetable organization, there be a higher or lower degree of respiration. But there are some facts which shew, that in the higher and more organized formations, and in a more vigorous activity of certain organs, more

atmospheric air is employed, and more carbonic acid is excreted. The mammalia, and birds in a perfect state, withdraw more oxygen from the atmosphere than amphibia and fishes in similar circumstances; birds more than mammalia; animals of aerial respiration more than those which live under water; many insects not only more than the mollusce and worms, but also than many amphibia, and when the temperature of the air is high, and they are in active movement, more than even mammalia and birds; an animal in the full bloom of age, more than the new-born, and the latter more than the embryo."

These researches are of the highest importance, and this is the only method of determining the relative intensity of respiration in different animals in different states of activity.

PHRENOLOGICAL SOCIETY OF LONDON.

SKULLS FROM THE MAURITIUS.—TESTS FOR PHRENOLOGY.

THIS Society recommenced its meetings for the season on Monday, the 2nd of November. Dr. ELLIOTSON, the president, in the chair. At the preceding meeting the president had read a letter from Sir James Mc-Grigor, inclosing one of which the following is a copy from Dr. Stewart, principal medical officer of the army in the Mauritius:—

"Medical Department, Mauritius,
Dec. 27, 1834.

"Sir,—I am commissioned to forward to England, and to your care, the skulls of four human subjects, which are considered of sufficient interest to claim the attention of all lovers of phrenological science. This I am directed to do upon condition that they shall be presented to the Phrenological Society of London, upon an engagement to furnish a copy of the result of their examination. Should they decline agreeing to this condition, it is requested that they may be forwarded to the cultivators of the same science in Edinburgh, and with the like injunction. The enclosed sealed packet contains matter relating to these skulls. This packet is to be retained in your possession unopened, until the report of the Society to which they are presented shall have been received; it is then to be opened, and the contents to be at your disposal, the observations of the Society, or a certified copy thereof, to be transmitted hither for the information of all concerned in this island. The heads are numbered, and the remarks upon them, contained in the enclosed packet, bear corresponding numbers. With the as-

The foregoing account of the developments of these skulls having been transmitted to Sir James McGrigor, the packet mentioned in Dr. Stewart's letter was transmitted to the Society, containing accounts of the characters of two of the individuals to whom the skulls had belonged; these characters having been furnished by the Chief Judge of the Mauritius, Edward Blackburn, Esq. a zealous phrenologist. Upon the characters of the other two individuals it appears that no particular observations had been made. The following were the details of the names and occupations of Nos. 1 and 3; and the same with the addition of the characters of Nos. 2 and 4:—

No. 1. The skull of *Parillon*, a native of Mozambique; a Government apprentice; and who died of phthisis on the 1st of Dec., 1834.

No. 2. The skull of *Pierre Gage*, or the Stutterer. This man, a negro slave, was tried on the charge of having murdered one of his comrades, and tried and convicted of a barbarous attempt to murder another, a female, upon the very slight provocation of accusing him of having stolen a pair of scissors. The latter crime was brought fully home to him, and the proof of the former only failed because the body of the deceased was never found, though diligent search was made on the spot where Pierre once declared that he had cast it; a declaration which he afterwards retracted; and which, from its having been made under coercion, could not be admitted as full legal evidence. It is supposed that the body was carried into the sea by a flood. The description given of his character by his master and other witnesses, his companions, and as it was illustrated by examples which they quoted, went to show that he was a man of great dexterity in all matters of handicraft, and a clever and skilful workman, but of desultory and roving habits; that he was sly and cunning, and constantly stealing from his companions; that he was extraordinarily jealous, and while under the influence of jealousy, quickly rendered ferociously irritable, most abusive in language, and violent in acts. The attack on his first victim was caused by slight attentions shown to his comrade, by his master, for good conduct. He was most libidinous in temperament; two examples of the disposition are striking. He made indecent propositions to a person in a class very highly above him; and only a few hours before his execution, on being kindly asked by his spiritual attendant whether he wished to have any thing, he answered "Yes, a woman." His intrepidity amounted nearly to insensibility at the place of execution; he mounted the scaffold boldly, examined the axe, talked freely to the executioner, and laid his head on the block without a sign of fear. Yet he seemed to be impressed with some sense

of religion. He confessed the attempt to kill, but maintained to the last that he was innocent of the murder. The Judge suspected that he imagined, that as death had not ensued in the former case, he had a chance of escape if he could remove the impression of his guilt in the latter. On the plantation he was strongly suspected of frequently firing the sugar canes and build-~~ings~~; certain it was, that from the time he was imprisoned to the present period, the burnings have ceased. He willed some money, which he had concealed in the ground, to one of his relations.

No. 3 is the skull of *Jean Malay*, or *Malgachi*, a slave who died of atrophy on the 1st of December, 1834.

No. 4 is the skull of *Rhagobury-Sing*, an Indian, who was convicted in India of killing one man and wounding two others, under circumstances unknown to the writer of this note. He was transported to Mauritius, and was for some years employed there as a convict. He was violently ferocious, and had a strong propensity to destroy. Sometime back he was tried, for having, almost without provocation, knocked down two men with a staff, nearly killing one of them by fracturing his skull. He escaped on the trial through an informality. He was afterwards convicted and executed for a murder, supposed to be committed in revenge for an insult offered to the family of the culprit, who was of a high caste. His behavior immediately after condemnation was brutally savage, but he afterwards became more quiet, and died courageously. He seemed irritated at his sentence, because no one saw him commit the act. He endeavoured to escape, and severely stabbed two persons who were employed to take him.

It thus appears, as Dr. ELLIOTSON stated, that there were two skulls of ordinary persons, and two of very depraved persons, and that the phrenological characters perfectly agreed with the biographical; the two former having probably been sent merely to occasion difficulty and put phrenology to a severer test.

While, however, one ordinary skull and one bad skull answered to the characters respectively given of them in the MS., it is remarkable that the other two skulls indicated each the character that was given of the other, in the MS., by which they were accompanied. Dr. Elliotson remarked that there was no possibility of mistaking the character of the skulls, and that, phrenology being true, he had no doubt that the skull marked 4 should have been marked 3, and that skull 3 should have been marked 4. He added that he had written to the Mauritius to this effect, confident that it would be discovered, either that a mistake had been made there, or that the skull had been wrongly marked, in order to more fully to test phrenology.

LONDON MEDICAL SOCIETY.

Monday, Dec. 7, 1835.

Dr. WHITING, President.

PLAN OF TREATING FRACTURES ADVOCATED BY MR. RADLEY.

MR. DENDY laid before the Society this evening, a specimen of badly united fracture, occurring below the cervix femoris; the head of the femur appearing to be almost twisted round, probably from the action of the muscles, so as to require some care in deciding from which side of the body the fractured bone was removed. The accident had occurred to a lady aged sixty-five years, from falling down six or seven stairs. A surgeon was immediately sent for, but he failed in detecting the exact nature of the injury, supposing, as no crepitus could be heard, that the neck of the bone might be fractured. She was put to bed, and nature was left to accomplish the cure, the attendant stating his inability to afford help in such accidents. This was what he (Mr. D.) would call, following Mr. Radley's plan of treatment, the doing nothing at all, and thus, by the specimen showed, doing worse than nothing. Mr. Radley had put forth his plan in so decided a manner, that he (Mr. D.) thought it justifiable to comment freely upon it. He considered that Mr. Radley had only given an *ex-parte* statement, and, therefore, one that was not to be noticed and acted on. Mr. Radley objected to splints in every case, because, as one reason, they gave pain; but this was reasoning from the abuse, and not from the use of splints; he (Mr. D.) had seen cases, and so must every practical surgeon, in which splints often relieved pain. And how? Why, by preventing spasms: and he was convinced that many cases occurred, in which the attempt to procure union without the aid of splints, would result in deformity of the limbs, and uselessness of those parts, as in the specimen now before the Society, where, although union had taken place, full three inches were taken from the stature of the patient, who was crippled for life. The surgeon had failed to detect crepitus, because some portion of synovia interposed between the fractured extremities of the bone.

MR. BRYANT thought that as the fracture was below the trochanter minor, the action of the muscles contributing to the badness of the union, this case was not a fair one to bring forward against the plan of treatment advocated by Mr. Radley, who spoke not of fracture removed at the upper part of the thigh-bone, and therefore he thought it improper for Mr. Dendy to speak of the treat-

ment generally in the terms he had employed.

A GENTLEMAN observed, that Mr. Radley did not mention any cases of fracture about the neck of the thigh-bone, and thought that his plan was a good one, as Mr. Radley had lost only two cases out of a considerable number thus treated, and those would have been incurable under any treatment. Nor did Mr. Radley object to the use of splints, simply because they produced pain, but rather because, when they were dispensed with, leeches and the local applications could be most beneficially employed, and this he believed was the chief source of benefit derivable from Mr. Radley's plan of treatment. It was useless, perhaps, to omit the use of splints, if the other treatment were not employed.

MR. CLIFTON believed that every new plan of treatment should be cautiously received, especially if the future welfare of the patient was likely to be affected if it did not succeed. In fractures, to bring and maintain the disunited bones in close apposition with little pain, was the object to be sought, but how this was to be effected by the simple use of pillows, he knew not. In the majority of cases the simple position would not do this; and without splints, ligamentous union would result. If the splints were properly adjusted, leeches and lotions might readily be applied; but on the whole, in fractures of the lower extremities, he thought the double-inclined plane the most advantageous method.

MR. HOORER agreed with Mr. Dendy, that splints rather prevented pain than caused it. In a case of fracture of the tibia and fibula, in which he had removed the splints, he found on the following morning that the woman herself had reapplied them, because she did not suffer when they were on, while without them the pain was considerable. He (Mr. H.) was also quite satisfied that it was impossible to keep the fractured portions in apposition without splints.

MR. ROBERTS mentioned a case of fracture of the tibia and fibula in both legs, that would set the question at rest. It first came under the treatment of a dresser at *St. Bartholomew's Hospital*, and fell under his (Mr. Roberts's) observation, producing at the time considerable impression on his mind, as to the great utility of splints in fractures. When the accident was admitted, great inflammation and tumefaction prevailed, and leeches were ordered. Excessive pain, however, continued, and was not relieved until the following morning, when one of the surgeons of the institution recommended the limb to be put into splints. Half an hour afterwards the pain was entirely gone: pretty tight pressure being used!

MR. CRISP regarded the last case as not bearing on the question at all. Would Mr. Roberts adopt the same kind of treatment

in all cases of fracture? He must confess that he could not tell how pain, inflammation, and tumefaction, were to be relieved by pressure.

Mr. DENDY wished that Mr. Radley's plan might ultimately be found to succeed. An apology was perhaps due to Mr. Radley from him, for speaking sharply of his proposals, and now therefore he begged to offer one. However splints might prevent pain, he would answer for their preventing spasm, and for preventing the fractured extremities of bones from grating the one over the other. Mr. Dendy then related two cases, which in the first instance were treated without splints, and in which perfect success afterwards attended the use of Mr. Amiesbury's apparatus.

Mr. BRYANT observed that the more he said on the subject of fractures, the more Mr. Dendy misunderstood him, and this arose from Mr. Dendy's not bearing in mind the seat of the fracture in which Mr. Radley's plan of treatment was recommended. He (Mr. Bryant) must confess that he knew nothing of fractures if it were true that all ends of fractured bones could be kept in apposition only by splints and tight bandages.

Mr. CRISP recommended that Mr. Radley's plan should be tried before it was condemned; for he had observed, and many others must have seen cases in hospitals, which would have done as well, if not better, without the confinement of splints, than they did with them.

GONORRHOEAL RHEUMATISM.

Mr. HUGHES, after a closing word on the subject of fractures, requested the members' opinion respecting rheumatism when occurring in conjunction with gonorrhoea. He had lately had under his care an unusually obstinate case, inducing him to think that the two diseases might be peculiarly complicated one with the other. His patient first had gonorrhoea, and on exposure to cold an acute attack of rheumatism supervened, affecting the shoulders, the knees, and the muscles of the back, but most severely affecting the small joints of the feet. He treated it as rheumatic gout, with colchicum and small doses of mercury. Another surgeon, however, was consulted, who immediately designated it as a case of gonorrhoeal rheumatism, and ordered the patient to drink porter and take sarsaparilla, and apply iodine to the feet, but as yet without benefit. The rheumatism followed about a week after the appearance of the gonorrhoea, and the two had now been under medical treatment for nearly two months.

Mr. PITCHER said that he had met with so many cases of rheumatism occurring in conjunction with gonorrhoea, that he had not the least hesitation in affirming that a

connection did exist between the two diseases, but what was the nature of that connection he was incapable of pointing out, though he had observed it to manifest itself mostly in the joints of the lower extremities. Bleeding and purging, as in common inflammation, were the measures he mostly resorted to, calling in the aid of colchicum, but small doses of opium, as in the form of the Dover's powder, he had found exceedingly beneficial. When these failed he gave mercury, which might be relied on. In answer to several queries he replied that he had frequently seen the disease prevailing in summer, and had found the patient recover without the aid of specific medicines.

Mr. DENDY believed that rheumatism prevailed at present very generally, but the disease assumed a neuralgic type. He begged to ask whether colchicum had been found so effectual when it attacked the neurilema or the substance of the nerves, as when it seized on the fasciæ and tendons of the muscles. For his own part, he had found it quite an indifferent remedy under this form of disease.

Mr. ROBERTS believed that gonorrhoeal rheumatism, as it was termed, was confined to the joints. He had found an ointment composed of equal parts of strong mercurial ointment, and the ointment of spermaceti (aa. ʒss), and camphor (ʒj), the most effectual in protracted cases.

Mr. HEADLAND did not doubt that a perfect form of rheumatism existed, induced by gonorrhoea. He had a patient who never suffered from an attack of the one without experiencing the other, following each other apparently as a necessary consequence. There was this phenomenon attending such cases, that the swelling of the joints was less, in proportion to the pain that existed, when the attack was one of ordinary rheumatism. He had not found colchicum under these circumstances an effectual remedy, but calomel and opium had proved invaluable in his practice.

The PRESIDENT said he believed that rheumatism following gonorrhoea, was totally distinct from any other species of rheumatism, and that it certainly was a specific disease, requiring a specific remedy. Colchicum only afforded relief by lowering the circulation in the treatment of rheumatism; he would say, that for muscular rheumatism colchicum was the best remedy; in neuralgic rheumatism the antiphlogistic treatment was demanded; and in gonorrhoeal rheumatism, or that form which affected the joints, he considered calomel and opium to be the most effectual remedy. So fully satisfied was he of the great efficiency of colchicum in muscular rheumatism, that he did not fear to say that nineteen cases out of twenty would yield to it.

A new patent hydraulic syringe, and an enema syringe were passed round.

WESTMINSTER MEDICAL SOCIETY.

Saturday, December 5, 1835.

Dr. Addison, President.

ECZEMA.

Mr. HALE THOMPSON exhibited some specimens of cuticle exfoliated from the hand, so entire as to bear an analogy to a kid-glove. The patient was affected with eczema. The man was a carpenter, aged twenty-four, pale, tall, and deeply marked with cicatrices of small-pox. He was admitted into the Westminster Hospital, 17th November 1835. The surface of the body in various places exhibits the cuticle in a state of desquamation, especially the thighs, the nuchæ, and the soles of the feet. The palmar surfaces of the hands and fingers have only recently parted with their cuticle, and are extremely red and tender. The general health is good, but anæsthesia detected an increase of the heart's action. Six years ago he had small-pox very severely after vaccination. He remained well for four years, when an eruption of vesicles appeared over the body, of the size of pins' heads, the intermediate portion of the integuments being of a deep red; the red rash preceded the vesicles by a day or two, with severe pain, heat, pricking, and itching; the vesicles shortly becoming bedded together, and presently discharging a watery fluid, the whole course of the affection occupying about six weeks, and apparently terminating in a mixed desquamation of the cuticle. With the local disease, there was considerable general disturbance. Twelve months after, a second attack, precisely similar to the first, appeared; and scarcely six months had elapsed, when symptoms of a third attack manifested themselves, followed by a general feeling of coldness. The man stated that he did not take, for the last attack, the powerful sweating medicines prescribed on former occasions. Up to the 24th of November, opiates to allay the restlessness, and bleedings and effervescing saline mixtures, with diuretics, and an aperient dose every alternate morning, were exhibited for the pain in the head and rigors; at this date the eruptions at the back of the neck were found to be confluent and containing serum, which night, without due care, have been taken for pus. Mr. White then recommended tonics, and the following were selected, as he conceived that the disease manifested a certain periodicity: sixteen grains of the sulphate of quinine, forty-eight minims of Fowler's arsenical solution, in eight ounces of water. With gum acacia, were directed, one to be taken three times a day, for four successive days, at the termination of which

time, as the symptoms were not ameliorated, he was ordered to return to the previous forms of medicines. The patient had not at either attack shed the nails, but they presented three distinct marks, showing thereby the degrees of growth during each attack; nor had the whole of the hair fallen off, but it was covered with an abundant scurf, and emitted a peculiar odour. The desquamation commenced where the vesicles were first observed, viz. at the upper part of the back, and about the axilla. He (Mr. T.) regarded the novelty of the case to consist in the periodical form it assumed, and he concluded by asking, whether this was a case of eczema.

The President believed that the case presented no new phenomenon, but would be found to coincide with the description given by Willan and Bateman.

Some discussion ensued respecting the vesicles in eczema, which the President said might be so small, that unless circumspectly observed, they might be overlooked.

Some remarks were also made on the combination of alkalies with quinine, which, however desirable, Dr. JOHNSON said would not add to the sensible properties of the materials, combined with the liquor potassæ, which gave to the mixture a putty-like substance that fell to the bottom of the vessel. For a knowledge of this fact he was indebted to Mr. Merson of Southampton-street.

Dr. CORLISS argued that if the sulphate of quinine were decomposed by the presence of the liquor potassæ, why should it not be by the two fixed alkalies? Ammonia, he was confident, would do so, and he was tolerably positive that it was changed by magnesia.

Dr. JOHNSON said he was not in the habit of combining magnesia with quinine, and therefore could not speak as to the result.

STRICTURE OF THE COLON.

Mr. SALMON then gave the history of a diseased colon which lay on the table. The preparation was taken from a lady, sixty years of age, who had enjoyed good health, but suffered from a remarkably costive condition of the bowels for a long time. When he (Mr. S.) was consulted by the desire of a physician who suspected it to be a case of intussusception, he presumed that a mechanical obstruction existed, as nothing had then passed for the space of twenty-four days, and two weeks more elapsed after his first seeing her without any evacuation occurring, or the least desire being felt on the part of the patient to empty the bowels, which was an important phenomenon, with reference to his views on the functions of the rectum. In order to institute an examination of the gut, an instrument two feet long was provided, and stricture found to exist fifteen inches up, at the sigmoid flexure

of the colon. The means employed failed, as was anticipated, and the patient died, though he felt persuaded that had a careful examination, and a scientific treatment been adopted at an earlier period, a perfect cure might have been effected. At the autopsy, a quantity of hard feces to the extent of three large chamber-utensils full, were found lodged beyond the stricture, and the colon, when removed from the body (with the rectum), measured at the caput coli, or largest part, fourteen inches in circumference, ascending thirteen, descending twelve, and at the situation of the stricture only one inch and a quarter, and its coats had become exceedingly thin. This case, he said, proved the possibility of detecting stricture high up in the canal, and also proved the occurrence of stricture in the colon, without a doubt.

A very long discussion followed. On the one side of the room it was argued that great impropriety and danger attended the using of long intestinal instruments, and that it was impossible scientifically to introduce them when soft, as in that state they could not be made to pass the different angles of the canal, as their exact situation could not be detected in the living subject. On the other side of the room these objections were considered as of no weight, Mr. Salmon explaining that the composition of the bougie he used varied from those in ordinary use, from containing nine-tenths more of common bees-wax, and consequently requiring nine-tenths more of heat to make it soft, which, although introduced soft, hardened by degrees as it remained in the body, first taking merely an impression of the strictured gut, and afterwards dilating it, which was manifested by the progress of the patient's health. No danger, he said, existed of piercing the coats of the intestines, his conclusions being the result of ample experience, during which he had not once observed that the extremity of the bougie was ever soiled with a speck of blood.

An adjournment then followed.

ROYAL MEDICO-CHIRURGICAL SOCIETY.

Tuesday, December 8, 1835.

MR. EARLE, President.

WOUNDS RECEIVED IN DISSECTING.

HONORARY diplomas were voted this evening to Dr. Faraday and Mr. Cline; according to a proposition made during the last session.

A paper was then read, on the treatment of injuries received in dissecting, by Mr. R. STAFFORD. The author remarked, that

these injuries were so frequent, and became so severe, and were so often fatal, as to be worthy of considerable attention. Some persons supposed that a peculiar virus was introduced into the system through the wound, occasioning, by its influence on the nerves and vascular system, the rapidly alarming symptoms which ensued; others supposed that the symptoms entirely depended on the part injured, such as the sheath of a tendon in a person of an irritable constitution or bad health, admitting a constitutional predisposition in either case. But the author thought that the phenomena could only be accounted for on the supposition that an animal poison was introduced into the system, as the most rapidly fatal cases often occurred where there had been but a slight abrasion, or a scratch received, and it was not probable that the sheath of a tendon had been wounded. Many cases also were recorded, in which no abrasion even was discovered, the most minute inspection rendering it most probable that absorption had taken place through the skin. The author's object now was, to relate several severe cases which had fallen under his observation, which he believed would tend to illustrate an appropriate mode of treating the injured part, and meeting the formidable constitutional symptoms which so frequently supervened. In the first case detailed, occurring to an M.D., the first symptoms manifested themselves on the day after dissecting a brain, the mischief apparently being seated in an elevated spot on the finger, the article being entire, from which the inflammation of the absorbents rapidly extended up to the elbow-joint. The Doctor was first awoken from a sound sleep, at four a.m., with pain, which speedily increased. At eight a.m. the pulse was hard, beating 90, and having a thrill or jerk. He Mr. S. ordered a colomet powder, and leeches to the part affected, followed by evaporating lotions, and a sedative draught. At mid-day Dr. Lee called in, and found the pain and inflammation on the increase, the pulse small and irregular, countenance anxious, and the patient suffering from excruciating pain in the lumbar region, with involuntary tremors, and twitchings of the lower extremities; in fact, the whole nervous system appeared as if it had sustained a most severe injury, such as was evinced after the bite of a venomous reptile. The nitrate of silver was applied to the injured part freely, and Mr. Lawrence was requested to see the patient. The tremors had continued, and the pains increased, and the skin was covered with a cold clammy perspiration, and hence the indications were, to alleviate the pains, and tranquilize the nervous irritability. Twenty leeches were ordered to the hand, and twelve grains of Dover's powder (which was instantly rejected), but a quarter of a grain of the

uriate of morphia was substituted for which remained on the stomach; it was not necessary to repeat the aperients, and the bowels were freely opened. Shortly after, the pulse became somewhat less, but the trembling, and the inflammation of the absorbents, remained the same. An incision was now directed to be made, but no pus followed, and the leeches were repeated. At four p.m. he was better, and the pulse had become more firm and strong. At this visit, it was remarked that the morphia ceased to produce effect after the expiration of two hours, and that if not then repeated the pains returned, when the exhibition of half a grain arrested them and induced sleep. By persevering in the free application of leeches, making incisions, and applying poultices and warm fomentations to the hand, with the internal use of the muriate of morphia and fever diet, the patient perfectly recovered from his alarming and desponding condition; but in spite of the active treatment, sloughing of the tendons followed, inducing a contraction of the joints of the impregnated finger. This case, remarked the author, demonstrated—first, the great utility of the sedative, and its equality, in the present instance, of santonin. Secondly, the propriety of opening freely the wound, although pus may not have formed. Thirdly, the value of the nitrate of silver, but to what extent it afforded relief could not positively be affirmed, as other measures to reduce the inflammation were adopted in combination with it. The next case was given as well illustrating the benefit resulting from opening the wounds early. In December 1831, Mr. P. received a wound from opening the body of a female who died of puerperal fever. As no puncture was perceptible, the patient did not suspect the nature of the malady, nor were the absorbents inflamed. Leeches were employed, and the antiphlogistic treatment was enforced. The constitutional symptoms, however, rapidly increased in severity, and the condition of the patient became most alarming. A swelling in the side appeared, the opening of which, although no pus followed, removed the tension, and the constitutional symptoms abated, and after the lapse of three months he recovered. The third case was quoted to prove the utility of the nitrate of silver. The fourth case was as follows:—Thomas B., an attendant in a dissecting-room, received a wound, followed by inflammation of the absorbents. Leeches and the nitrate of silver were applied, and he was directed to take a calomel powder, followed by a brisk aperient. Under this treatment he recovered. In March 1835, he received a second wound, but took no notice of it until four days had elapsed, although he suffered severely during that period. The constitutional symptoms were then

severe, and although the inflammation was found not to extend beyond the sphere of the action of the nitrate of silver, the other remedies failed to arrest the progress of the disease, and on the second day after his applying for medical assistance, coma succeeded, and the patient sank. On an examination of the body after death, it was found that pneumonia had assisted in producing the fatal result, which forcibly showed the necessity of not delaying to apply for relief. Some observations were afterwards made by the author on the propriety of general blood-letting. Generally he thought it not advisable to employ it, owing to the great degree of nervous debility present. This view seemed to be supported by the result of the cases published by Dr. Duncan in the *Med.-Chir. Trans. of Edin.*, who stated that when employed, the patients never rallied. The good effects of topical bleeding were evident, and in those cases in which it was used, matter did not form in the axilla. With regard to the question, how should the swellings be treated, whether pus was or was not formed, he (Mr. S.) would recommend free openings, from the good effects following which, in the present case, before it was known if pus was present, that Mr. Lawrence was led to adopt the practice. The author concluded by briefly referring to various cases to prove the propriety of laying open the parts early, showing that where not had recourse to death was the result. He also recommended the support of the system by a tonic plan, other symptoms that arose during the progress of the disease, being treated according to the best methods laid down in surgical works.

Mr. MAYO recommended that a free opening should be made in every point of the swelling, not resting satisfied with a single opening.

A MEMBER observed, that when the inflammatory symptoms migrated from one part of the body to another, the constitutional symptoms were less severe, and the local symptoms more protracted.

Mr. MACLEWAIN maintained that many cases of erysipelas presented symptoms which were—he would not say analogous—but precisely similar to those arising from the absorption of animal poison. He objected to the application of numerous leeches, on the same ground that Mr. Stafford would be cautious in the use of the lancet.

The PRESIDENT indicated the necessity of free and early incisions to prevent the ill consequences of tension of the parts. He remembered the case of a pupil, where the symptoms were so terrific, that no hope for a moment was entertained of his recovery, and where the powers of life were so enfeebled, that the loss of the smallest quantity of blood would probably have sunk him.

He requested Mr. Lawrence to see him, and Mr. L. sanctioned (before he, Mr. L., taught the advantages of incisions) the opening of a tumour which had formed in the side, as the pain increased. One hour after, it was found that an alarming hemorrhage had occurred from the wound, of not less than thirty ounces, after which the pulse rose, and became fuller, and, contrary to the opinion formed from the debility present, the patient progressively recovered. Where the inflammation proceeded from the absorbents, and was characterized by red lines, he advised the free use of the nitrate of silver.

Dr. LEE observed, that when no external traces of inflammation, or other symptoms, appeared to account for death, he believed the fatal event would be found to have ensued from the inflammation attacking the deep-seated veins.

Dr. ELLIOTSON related three cases to illustrate amongst other positions that matter could be absorbed in dissection, without an abrasion of the surface. In one case it appeared, that the finger had simply been rubbed down an arm in a gangrenous state, when dry vesicles appeared on the patient's finger, unattended with inflammation, followed by pain and tumefaction of the side, which was opened without matter appearing. A remarkable phenomenon presented when the body was examined; all the viscera were so soft, that the finger could be passed into their substance with the greatest facility. In the other two cases, dry vesicles also appeared under similar circumstances. The patient was of an exceedingly nervous temperament, and the symptoms were regarded at first as of a rheumatic nature, but shortly after, sharp lancinating pains occurred in the side, followed by swelling. The nitrate of silver was applied, and the redness disappeared, but matter formed, unattended with any further inconvenience; no other local symptoms appeared where the eruption occurred. But the same accident occurring to him (Dr. E.), the poison being imbibed from a similar source, and in the same manner, only slight local symptoms followed, unaccompanied by any constitutional derangement, in consequence of his being of a robust constitution, but the pimple remained for full two months. He concluded, from the facts he had observed, that the symptoms which follow, whether local or constitutional, or both combined, do not result from the application of the poison to particular parts or structures, but rather depend on the peculiar nature of the constitution of the person infected.

The meeting then adjourned.

REPORT OF MEETINGS

OF MEDICAL GENTLEMEN

AT TUNBRIDGE WELLS,

TO DISCUSS THE OPERATION OF THE

POOR-LAW MEDICAL CONTRACTS.

At a meeting of the Medical General Practitioners residing at and in the neighbourhood of Tunbridge Wells, held in that town on the 24th Sept. 1835, for the purpose of considering the effect of certain clauses in the Poor-Law Amendment Act, on their interests, and the welfare of the sick poor.

It was resolved,—That while this meeting disclaims any factious opposition to the new Poor-law Commissioners, they feel it right to form a Committee for the purpose of watching the operations of the Poor-law Amendment Act on medical interests, and that Messrs. West, Stirling, and Way, be appointed such committee, the members of this meeting, at the same time, pledging themselves individually not to enter into any contract for the whole, or any district of a union, with the guardians of the poor, excepting with the concurrence of the above-named Committee. The above resolutions were then signed in form by the members present, who consisted of the following gentlemen:—

Isaac Hargreaves.	Peter Brown.
William J. West.	John Shorne.
William Wallis.	Charles Trustram.
Robert J. Stirling.	E. H. Finley.
Christopher Fenold.	Robert Gibbon.
David Henry.	John Outcald.
W. Way.	Jonathan Monckton.
William Wisden.	Stephen Monckton.

JAMES CORNWALL, Chairman.

Shortly after this meeting, the Assistant-Commissioner, Sir F. Head, and the Board of Guardians, gave notice to the medical gentlemen of the district, that they had decided on allowing 250*l.* per annum as the salary for attendance on ten parishes, comprising a large and widely-scattered population, the former salary for the same attendance having been 170*l.* On the receipt of this communication a second meeting was called, and held on the 11th Nov. 1835, when

It was resolved,—1*st.* That a communication having been received from the guardians of the poor of the Tunbridge Union, stating that they had apportioned the sum of 250*l.* per annum for the whole medical and surgical attendance (excepting midwifery) in such Union, this meeting laments the practice which has been adopted in other unions of obtaining medical officers for the poor by threats, held out to compel them to take the contracts on the oppressive and inadequate terms which had been proposed, and that they consider such a course as degrading to the profession and injurious to the pauper poor (the urgent cases involving life), and that such payment for providing "efficient medical and surgical attendance on the poor," cannot be accepted.

2*nd.* That trusting we have to treat with

men, capable of offering the value of medical services, and the fair claims of the sick poor, we hope to meet them on something like fair and adequate terms.

3rd. That a Committee, consisting of the four following gentlemen, be deputed to wait on the Board of Guardians at their next meeting, to present and support the resolutions of this meeting. Mr. Monckton, sen. (or jun.), Mr. Cornwall, Mr. West, and the chairman of this meeting, or such other gentlemen of the present meeting as they may depute.

(Signed) ISAAC HARGRAVES, Chairman.

The above-named gentlemen (Mr. Way, in Mr. Cornwall's absence, taking his place) waited on the Board of Guardians, when the Chairman, Mr. HARGRAVES, read and presented a copy of the resolutions, and stated that he was instructed to urge on the consideration of the Board, that the medical men were badly paid at their former salaries, so that the offer now made, of little more than half that amount, was unjust to the poor, as well as to the profession. He requested also to be informed what the precise duties of the medical men would be.

Mr. Hargraves was here interrupted by Sir F. Head, who said that he would not give the least information to parties who came as the deputation had done; that the language of the former resolutions, as well as of the present, was highly improper to be used to him, and that it was evident the deputation had come for the purpose of insulting and abusing him, and that such conduct could not be tolerated.

The CHAIRMAN of the deputation immediately disclaimed the most distant intention of offending, much less of insulting, Sir F. Head, and the Board of Guardians, and though he still contended that the language complained of was that of truth, he would, in accordance with the feeling of the Board, and at the suggestion of an influential member of it, withdraw the objectionable words "threats held out" and "oppressive."

This proceeding was satisfactory to all parties but Sir F. Head, who resumed his vituperative and insulting strain of language, endeavouring to impress on the Guardians and the deputation, that their language in addressing him was highly unbecoming and improper.

The CHAIRMAN of the deputation upon this appealed to the Board to say, whether, having, in compliance with their wish, withdrawn the offensive words, Sir F. Head was justified in thus treating the deputation, and he (the Chairman) would now individually tell Sir F. Head, that he (Sir F. H.) had no right to speak as he had spoken, and that he (Mr. Hargraves) cared not, after his treatment of the deputation, whether he felt insulted or not. The Chairman was here interrupted, but on again resuming he justified the truth of the assertion that "threats had been held out" to the medical

men, by quoting the words of Sir F. Head at Tunbridge, to the effect, that if the medical men of the Unions would not take the contracts on his terms (at the same time boasting that he had reduced them nearly, or quite, half), competent men from London would be brought down, who would gladly accept them for the advantage of an introduction to private practice.

Sir F. Head admitted that such had been his words, and angrily added that he would repeat them.

Mr. Way next addressed a few words to the Board, and showed, by a reference to the resolution itself, that it could not be meant that that Board had used "threats," or were treating the medical men oppressively, but that on the contrary, they were hoping to meet them on fair and honourable terms. Mr. Way begged to ask the Board on what calculation or data they had fixed the salary of the medical officers, and, from a statement produced to the Board, he showed, on the part of the medical men, that the average remuneration of his own services in one parish, was only *one penny* for each patient actually attended, *including medicines*. He objected also to the principle on which the Board were proposing to act, as pressing most unfairly on one class; and observed that on such a principle, it would not be difficult, without for an instant impugning the ability of Sir F. Head to execute the duties entrusted to him, to find numberless individuals, equally qualified, who would gladly take his situation, with half the emolument.

Sir F. HEAD, in reply, acknowledged that the compensation was *inadequate*, and further observed that the principle upon which he had invariably acted was to give the preference, in the appointments, to those gentlemen who were already in possession of the parishes; and that *notwithstanding what had passed*, the same principle would, in the PRESENT INSTANCE, be adopted.

16th Nov. 1835, at an adjourned meeting, &c. &c.,

It was resolved,—1st. That this meeting receive with much concern the communication from their deputation, of the refusal on the part of the Assistant-Commissioner and Board of Guardians to alter their decision as to the amount of salary to be given to the medical officers of this Union, and do express their deep sense of the injustice of such determination, as affecting the interests of the poor, as well as the medical profession in general.

2nd. That this meeting concurs in the *expediency*, of accepting the terms named by the Board of Guardians.

3rd. That Mr. West be requested to confirm the contract in behalf of the meeting for Tunbridge Town District, Mr. Monckton for that of Brenchley, and Mr. Way for that of Tunbridge Wells, and that in case of any difference of opinion, or difficulty arising, in defining the limits, or appropriating the portions of duty or salary, Messrs. Prince, Hargraves,

and Cornwall, be appointed as referees, and their decision to be considered final.

4th. That on entering into the necessary contract with the Board of Guardians, this meeting do request the gentlemen so contracting, to present a protest against the conduct pursued towards them, whereby they have been compelled to undertake duties, without anything like an adequate remuneration.

5th. That the following be the form of such protest:—"This meeting most respectfully, yet most firmly, protest against the conduct which has been pursued towards them by the Assistant-Commissioner and Board of Guardians, by which they have been compelled to accept of terms for their professional services, which they feel to be degrading to themselves. They have asked for, and have been denied, information as to the grounds upon which the Board have decided on the amount of their salaries. They have presented to the notice of the Board a statement of their past services and remuneration, and it has been admitted by the Assistant-Commissioner that an adequate compensation was not allowed. It has been avowed that upon their refusal to accede to the proposed terms, strangers would be introduced into the districts, to the manifest injury of the present medical practitioners. Such avowal must be deemed as a threat to those whose interests are so intimately concerned thereby. They consider, also, that the sum proposed has been determined upon, without due regard to the required duties, and at variance with the remuneration allowed in other Unions. Under these circumstances, this meeting feels justified in declaring that the manner in which its members have been treated has been unjust, arbitrary, and oppressive, and such as could not have been contemplated by a wise legislature."

(Signed on behalf of the meeting.)

On the day appointed by the Board of Guardians, Messrs. West, Mouckton, and Way, attended the meeting. There was also in attendance (but of course not with the deputation) an individual who, alone of all the practitioners in the district, had from the first declined acting with his professional brethren. The names of the members of the deputation were sent in, with a statement that they were waiting for an interview, and after some little time, Mr. Mouckton was called before the Board, when the Chairman announced to him that he had been unanimously appointed to one of the districts, upon which Mr. Mouckton replied that he thanked them for their unanimity, but could not thank them for the appointment. Mr. West was then appointed to another district, and in reply Mr. West said that he felt the appointment was forced upon him, and that he would give any one twenty guineas above the salary to perform the services. Immediately after this to the great surprise of the deputation, the individual above alluded to as not forming part of the deputation, was appointed to the remaining district without the least explanation on the part of the Board, or even the slightest notice of what had been done being made to the deputation!

26th Nov. 1835.—At the adjourned meeting, &c. &c.

It was resolved,—1st. That this meeting express their deep sense of the apparent injustice which the Board of Guardians of the Tunbridge Union have committed, in appointing a gentleman who has been less than four months in the district, to the charge of the sick poor of four parishes, which have hitherto, for many years, had the attention of five of the oldest practitioners of the place and neighbourhood, who were willing, if required, to continue their services for such purpose, on the proposed terms. This meeting feels, that such appointment has been made in violation of the principle and the public pledge of the Assistant-Commissioner himself,—namely, "that those who already had the attendance of the parishes, should have the preference given them in the new arrangement." In the absence of all explanation from the Board of Guardians, the meeting is compelled to conclude that the appointment has been made, they will not say in a spirit of vindictiveness or resentment, because its members have dared to remonstrate against grievances imposed on them, but certainly without due consideration.

2nd. That the Chairman, with Messrs. Cornwall and Way, be requested to form a committee, to give publicity to the proceedings of this and former meetings, as they may think proper.

3rd. That this meeting be formed into an association, and that it be called "The Medical Association of the Tunbridge Union."

Signed on behalf of the meeting,

J. HUGHES, Chairman.

A Copy of the above was then directed to be forwarded to the Board of Guardians, to be laid before them at their next meeting.

THE LANCET.

London, Saturday, December 19, 1835.

THE proposal for establishing a national University in this metropolis, is exciting very general attention, and there are few persons to be found, even in the ranks of the bigots, who offer any serious opposition to the scheme, as it has been propounded by the friends of the Ministers. The founding of the Institution, therefore, is regarded as a matter of certainty, and the public have only now to consider on what terms, or "conditions precedent," the degrees or honours of the University are to be awarded. As experience has proved that all inequalities are injurious to the interests of the community, we are anxious to see the

University founded in London, upon principles which can receive the unqualified sanction, not only of the well-informed people of this country, but of all the enlightened men of Europe. Assuredly, therefore, it cannot command so great an extent of admiration and respect, if the CHARTER OF INCORPORATION give to the conductors the power of raising up obstacles, in the form of CURRICULA, which shall prevent all persons, excepting the students of a few favoured institutions, from being received as the legitimate candidates for degrees. Such obstacles would create another monopoly of a scarcely less objectionable character than that of Oxford and Cambridge. The principles of government, in order to be *just*, must be *simple*; but there is neither justice nor simplicity in withholding from genius and talent their full share of honourable reward. The production of "certificates of attendance," too often given by the professor in the absence of any personal knowledge of the student, cannot increase the acquirements of the candidates, either in number or utility. If the great scholastic institutions which this charter, it is supposed, is designed especially to favour, do not dread a competition with the private, less ostentatious, more retired establishments, in many of which are taught the higher branches of knowledge, how can the conductors and supporters of the former honestly and reputably contend that all students ought not to be placed upon an exactly equal footing in the Examination Hall of the new University? If distinctions be made, if exceptions be introduced, they must operate as unjustly in London as they have already operated in Oxford and Cambridge. If it be not the object to confer honour upon the acquirements of genius, let an acknowledgment to that effect be made at once; and if it be the intention to confer titles in learning and science, as a species of reimbursement for the expenditure of so much money under the operation of a ticket-and-certificate sys-

tem, then, also, let *that* intention be honestly confessed. If the exceptions to which we have here briefly adverted, be actually made in the new charter, the public will naturally and correctly conclude, that there exists a desire, from some motive or other, to give an *artificial* value to the education of persons who are instructed in particular establishments. Such a proceeding is not fair. It is infinitely beneath the object of a great and liberal government, and the scheme would no sooner be in operation than it would be productive of very general dissatisfaction; the honours which it would be designed to confer, would carry with them no weight or importance among the enlightened portion of the community. We refrain, however, from now offering another word on the subject, in the hope that the advisers of the Crown will take the earliest possible opportunity of publishing a draft of the charter which it is their intention to frame for founding and governing the metropolitan University. When this document is before the public, then, and not until then, shall we be placed in a position to object, by petition and remonstrance, to the obnoxious clauses, if there be any such, in the new royal instrument.

THE following note accompanied the communication which will be found at page 466 of the present Number of our Journal:—

To the Editor of THE LANCET.

Sir,—As secretary (*pro tempore*) of "The Medical Association of the Tunbridge Union," I am requested to forward for your information, and, should you think proper, for publication also, the minutes of the proceedings of our different meetings.

I have endeavoured to give you all the facts connected with them as concisely as possible, and our object in sending them is, through your means, to invite our professional brethren to form local associations, to terminate in those of the county, and under the idea that one or two gentlemen from each county might unite to form a deputation to his Majesty's Ministers, for the purpose of obtaining redress of the grievance. I am, Sir, your obedient servant,

W. WAT.

Tunbridge Wells, Dec 1, 1835.

In placing this note before our readers we may state, that although we approve of the purpose therein mentioned, we consider that if medical gentlemen would but combine to suggest a plan for amending the state of the law with regard to the treatment of the sick poor in the new parochial unions, it would be infinitely preferable to making any application to the Ministers on the subject. It is not right either that the sick poor of this kingdom, or the surgeons of England, should be left to the mere mercy of any set of men, whatever may be their station, their respectability, or the benevolence of their intentions. Experience has already proved that *the law* is defective. It is *the law*, therefore, that must be made more perfect; but it cannot be expected that the members of the Legislature will be very hearty in their condemnation of the proceedings of the Poor-Law Commissioners, or their assistants, unless medical gentlemen can themselves point out what ought to be the rule of law which should invariably be observed in making the contracts between Boards of Guardians and parochial medical attendants. We hope, therefore, should deputies from the county associations assemble in London, that they will visit the metropolis fully instructed by their constituents as to the plan for which the medical practitioners of England would be anxious to obtain the sanction of the Legislature. It is quite evident that there must be some definite settlement of the question out of doors before it can be brought forward again within the walls of Parliament.

The insertion of the communications of Mr. WAY would have taken place last week had not a want of space rendered their publication at that time impossible. The statements contained in the reports are calculated to excite the utmost feelings of indignation against the authors of the insults offered to the deputation, in the mind of every man of correct gentlemanly feelings who peruses them.

The Chair of Surgery in the University of Edinburgh, vacated by the death of Professor TURNER, has been conferred in a very honourable and flattering manner on our distinguished anatomist and physiologist, Sir CHARLES BELL. The only thing we have to regret in making this announcement is, that the emoluments of the office are not commensurate with the value of those services which Sir CHARLES BELL has already conferred on mankind. The following paragraph relative to this appointment, is taken from the *Courier* of Dec. 12:—

“The Reformed Town Council of Edinburgh have done themselves great credit by their unanimous appointment of Sir CHARLES BELL to the important Chair of Surgery in the University of Edinburgh. We cannot conceive a more disinterested or praiseworthy discharge of public duty. There are at present several surgeons in Edinburgh, of distinguished ability, though unquestionably not one of them enjoys the high professional reputation which Sir C. BELL has deservedly attained, most especially as a public teacher; but all applications for any individual excepting Mr. LISTON, whose eminence as a surgeon is universally acknowledged, were entirely disregarded, and as soon as it was ascertained, by reference to Mr. LISTON, who has lately settled in the metropolis, that he would not forego his prospects in London for any of the medical chairs in the University of Edinburgh, the members of the Edinburgh Council resolved, painful as it was to the feelings of some of them, not to pay the slightest attention to the private solicitation of friends, but at once to elect Sir CHARLES BELL, as by far the fittest individual who was willing to accept the situation, and thus to uphold the fame of the first medical school in Europe.”

Had Mr. LISTON accepted the invitation of his countrymen to return to Edinburgh, and taken the Chair of Surgery, he would have acted, we think, most injudiciously. Within the short space of time that he has already resided in the Metropolis, Mr. LISTON has succeeded in establishing his reputation equally well founded with that which he had previously acquired by the exercise of his scientific attainments in Edinburgh. If he could have been induced to quit the Metropolis by the offer of the

friends in the English capital, the students of the University, would have incurred an irreparable loss by his secession from that establishment.

INTERCEPTED LETTER.

"DEAR DOCTOR MACMICHAEL, — I am determined to print my last oration, as all my friends tell me that the Latinity of it is elegant, and that the whole is in good classical taste. Perhaps your friend MURRAY would publish it as a shilling pamphlet, illuminated with a view of Pall-Mall-East, as a frontispiece. I will undertake to sustain all losses in case he should fear to print it as a bookseller's speculation. It may give our sacred cause a lift, and we ought not to throw away a chance in these hours of confusion and alarm. It will also promote our interests to get it reviewed, a duty which you can desire FERGUSON to perform in the *Quarterly*, but pray caution him not to use so much filthy language—or what people of good taste call *flummery*—as he did in the review of my former orations. I require no puffing. My classical acquisitions are universally acknowledged. I desire him to write nothing laudatory of them, but to confine his critique to the scientific and high moral feelings which abound in the oration.

"I have received a most interesting, but, I lament to add, a most painful and vexatious communication from my correspondent in Downing-street, and although at this early period I would not have the fact whispered, yet I tell you that the bubble, as the radicals call it, must soon burst, and therefore let us hope that by early information on what the Government is contemplating, we may make at least some effort to parry the blow which awaits our ancient and venerable institution. It appears that the 'Central Board,' the very name of which is sickening, and about which we heard so much during the Parliamentary inquiry, is contemplated to be formed in right earnest, the Government having determined, to the joy I suppose of all the liberals and radicals, to form such a Board, under the auspices of a Metropolitan University. This university is to comprise a body of Examiners, to be selected from all grades of the profession, except the teachers of the different schools, the Examiners of our own College, and, of course, the Council of Lincoln's-Inn-Fields, and it is intended that this enlightened body shall have the power of conferring degrees (following singularly enough the example of our College), on all those who can exhibit competent medical knowledge, so matter whence it has been obtained. It is impossible to glance at the

establishment of such an University without horror. It strikes at the very foundation of our vested rights, and will wipe away, like a sponge, the whole of the certificate system, under which our esteemed friends have so greatly benefited. It will destroy all the exclusive advantages and privileges which our recognised schools and hospitals have so long possessed, and it must inevitably destroy those rational sources of income and emolument which are derived by all our present Colleges and Corporations, from the trade in degrees and diplomas, as no one can now be expected to disburse those large sums which we all demand for collegiate documents.

"You, my dear friend, are perfectly aware of the great difficulties into which we have lately been plunged in consequence of scarcely an individual having applied for a license from our College during the last two years, and if our funds are so bad now, what will they be by-and-by? This metropolitan university will be no less fatal also to our friends in Lincoln's-Inn-Fields and Bridge-street, Blackfriars, as those to whom they grant diplomas and licenses will of course be freed by the Government from having anything more to do with the College and Hall corporations. In fact, the game seems to be altogether up, and what to do and what to say I know not. It is, indeed, most mortifying to me that I have never been consulted by any member of the Government in their various arrangements, as I might, by some means or other, have caused delay, even if I could not have got some important alterations made in the plan. I now see the misfortune of having tampered with Sir ROBERT PEEL and my Tory friends, during their short reign, for I suspect that the present men doubt my sincerity, and avoid asking my counsel.

"Much as I may regret it on account of my health, I must come to London at the latter end of the month. I will then make the necessary arrangements for getting up the evening recreations at Pall-Mall East, to accomplish which, however, I see many and serious difficulties. I must also call the attention of the Fellows to the sinews of war, a matter fraught with anxieties, as there have been so few monies received for licenses lately. The College building is already so heavily mortgaged, that it will require a much deeper financier than myself to keep the machine in motion.

"King's College claims at this moment, as it has ever done, my earnest solicitude, more especially as my dear nephew's fate in life has been embarked in that school. By-the-by, I should be glad if you could devise some mode by which it could be made generally known that the vacated chair was not *his* chair, but that of Dr. Bissett HAWKINS, his cousin, also a Fellow of our College. I am naturally most anxious that

these two eminent professors should not be confounded, and mistaken the one for the other, because I am well aware that the office to which Dr. Bissett was lately appointed, and which was with difficulty obtained for him by me, he was compelled to accept from the little chance which he had in the Strand of obtaining emolument from his professorship. Moreover, such an office as Inspector of Prisons must be regarded as quite below the dignity of my nephew. Things are, indeed, come to a sad pass when one of our most learned Fellows, a professor, too, of King's College, is under the necessity of accepting the office of 'Inspector of Prisons.' Heavens! What a degradation for a man of classical learning and high moral feelings, to be placed in a situation where his chief associates will be criminals and their safeguards! Do, therefore, endeavour to let it be generally known, — and MACLEOD might be desired to give a paragraph on the subject,—that the newly-appointed inspector of prisons is Dr. Bissett HAWKINS, formerly professor of *materia medica* in King's College, Strand, and not my dear nephew FANNY HAWKINS of the Middle Sex, as I hear that some designate him; the celebrated professor of the practice of physic in King's College, and registrar of our College.

"My anxiety has also been directed to find a competent successor to the vacant chair of *materia medica* among our Fellows, for although it may be quite within the capacity and calling of a licentiate to teach the difference between rhubarb and ipecacuanha, yet we must not give those subordinate licentiates a footing in the Strand. We must get PARIS, if possible, to close with the proposals that have been made to him, and you must explain to him fully how matters stand. Express to him my high opinion of his talents and moral character—the elevated position he fills in the scientific world,—the gigantic powers of his mind,—the celebrity of his numerous writings,—and, above all, the unbounded sentiments of friendship which I have ever entertained for him, and the great anxiety I have always felt to assist him in life. These, and all these sentiments, properly explained to him, one after the other, from day to day, will most likely induce him to acquiesce at once in my wishes, by accepting the chair. He is a shrewd-enough man to see that neither profit nor honour can reward him for the toil and vexation which he will endure in compiling lectures to deliver to empty benches; but he must be cajoled, and brought over by promises of better things and better times; though, between you and I, my dear friend, there seems little chance of my being able to do anything for him. I have already made more promises than I can fulfil, even were

I to live for a hundred years; but circumsanced as we now are, it is quite legitimate to make promises conditionally, as such can do no harm, even if they do no good to our cause.

"I lament to hear of the illness of my dear old friend Madame VESTRIS. To visit her is a sufficient reason for my hastening to London. Pray call and tell her so with my love. I am confident that, knowing her so well as I do, I can be of use to her. She is a charming creature, and I am not the only one who would miss her, as she certainly has always been, and still is, a general favourite. Remember me kindly to all the Fellows, and express to them the delight I feel in the prospect of again meeting them so soon in Pall-Mall-East. God bless you all. Ever yours,

"* * *

"November, 1835."

KINNERTON-STREET SCHOOL. —To the Editor.—Sir, I perceive, in a letter from a correspondent in your last Number, a statement relative to the number of pupils attending the Kinnerton-street School of Anatomy, which letter is evidently written by a person totally ignorant of the subject, or wishing to pervert the truth. As a pupil of the school, I trust I may be allowed to set him right. The real number of new pupils that have entered is forty-two; which, with several personal friends of the lecturers, make a much larger attending class. For the truth of this, I beg to refer to the register which lies on the table in the museum, for the inspection of any person who wishes to examine it. Trusting you will give insertion to this,—I am Sir, yours very obediently, JAMES EARLE.

Kinnerton-street, Dec. 9, 1835.

Surely A Friend of THE LANCET is mistaken. He will, however, greatly oblige us by stating, at once, in confidence, his reasons for believing that the author is Mr. R. We can show good reasons, at present, for doubting the correctness of the allegation.

Very many of the communications lately forwarded to us will be inserted. Want of space only, in appropriate parts of the Journal, has yet kept them from publication.

A correspondent informs us "that Dr. Webster only lectures at King's College for his friend Dr. Hawkins, and until Professor Paris undertakes the duties of the chair of Mat. Med." We have not had room for the long communications from various parties who feel interested in this complicated affair of appointments and retirements and reappointments. Did Dr. J. ***** really wish his letter to be published?

ERRATA.—Page 411, line 10, for *appropri*, read *opprobria*. Page 316, col. 2, line 54, for *oppositio*, read *oppositio*. In the remarks of Mr. Streeter at page 318, the passage commencing at line 1—should stand thus:—"increased irritability of temper, (Mr. S.) would ask, Does temper belong to the intellect? Certainly not, but it is a quality. With regard to the next passage, (Mr. S.) would (and it difficult to make a better one) read thus:—"

[1835-36.

LECTURES ON DISEASES OF THE BRAIN AND NERVOUS SYSTEM.

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE V.

INFLAMMATION OF THE SPINAL MARROW.

It has long been known, gentlemen, that the contents of the vertebral canal are subject to inflammation, as well as the contents of the cranium, but it is only within latter years that the disease has been studied with great care and attention.

Inflammation of the spinal marrow, known by the name of *myelitis* in the important work of M. OLLIVIER, may be distinguished into two forms, the acute and chronic, but instead of pursuing each of these forms separately, I shall lay before you a general idea of both together, taking care to dwell on the characteristic points that are peculiar to each.

The Anatomical Characters of Myelitis,

or inflammation of the spinal marrow, are the same as in encephalitis; it is, therefore, unnecessary to recur to them here; you have the same injection and thickening of the membranes; the same induration or ramollissement of the nervous substance; the same suppuration in the interior of both organs: indeed, this is a necessary consequence from their identity of structure. However, diseases do not occur with the same frequency in the one as in the other.

Diseases of the substance of the spinal marrow, which we have not many opportunities of observing, M. VELPEAU published a very striking example of

this affection. From the united effects of ramollissement and suppuration taking place in the substance of the spinal chord, and gradually operating its destruction, we sometimes have a very remarkable circumstance produced, viz., the nearly complete separation of the spinal marrow into two distinct parts. In some cases the abscess has been found so extensive, that the superior and inferior portions of the chord were merely held together by a few ragged shreds. Of this we have more than one example in the science.

The lesions accompanying inflammation of the spinal marrow may vary in seat, from one extremity of the chord to the other. Th myelitis may be general, or it may be partial, and the latter form is fortunately more frequently observed than the former. When the myelitis is thus partial, it may occupy any portion of the chord; but it is usual to distinguish it into three principal forms, as it may affect a portion of the spinal marrow corresponding to the *cervical*, the *dorsal*, or the *lumbar* regions. Again, whatever part of the length of the chord may be involved in inflammation, this latter may occupy either the whole thickness of the chord, or its anterior, or finally, its posterior column only. All these subdivisions are not made for the sake of arrangement: they will present themselves to you in practice, and are of importance to be noted, because in many cases they give an explanation of the nature of the symptoms we observe.

Besides the divisions which we have just pointed out, the inflammation may engage either the white or the gray substance of the spinal marrow; the latter is much more frequently attacked than the former; and when the inflammation occupies the centre of the chord, giving rise to a softening of its substance and destruction of the nervous tissue, we may have a vacuum produced, or a true canal, analogous to the normal one which exists at a certain period of fetal life. I had an opportunity once of seeing a case of this kind in an old man: the centre of the chord contained a canal hollowed out by the suppuration, and which at first sight might have been mistaken for a natural cavity.

The Causes of Myelitis

are the same as those of encephalitis. Inflammation of this portion of the nervous centre may equally be produced by external violence, such as blows, falls on the back, &c. It is also frequently produced by disease in the neighbouring parts, especially in the bones comprising the vertebral column. Finally, inflammation may be occasioned simply by too strong an action of the part. You know that encephalitis is sometimes occasioned by intense study, over-exercise of the intellectual faculties, violent passion, &c.; in the same way, neglect may be produced in cases where the action of the spinal marrow is carried to a high degree of intensity. Thus in animals which have been over-worked, or which are compelled to make violent and long-continued muscular efforts, M. Dupuy has found more or less trace of inflammation of the spinal chord after death.

The Symptoms of Myelitis.—The division of lesions occurs according as the functions of nutrition or of relation may be deranged. In the first place we may have several of what we may term negative symptoms: the intelligence is usually intact, we do not observe delirium &c., if the inflammation occupy no other part than the spinal marrow; the patient is free from headache, giddiness, and other symptoms of cerebral irritation. We are, however, to except cases where the inflammation engages or may extend to the upper part of the chord: when the medulla oblongata becomes implicated in the disease, we may observe agitation, delirium, coma, and other phenomena, arising from the proximity of this part to the great centre of the nervous system. The derangements of mobility naturally occupy a principal part amongst the symptoms of myelitis; they are very various, and predominate over all the others. In some cases the faculty of motion is extensively compromised, and hence after death you will generally find that the inflammation occupies the anterior pillars of the spinal marrow. This pathological fact is perfectly in accordance with the physiological experiments of M. MAGENDIE, who as you know has proved that the anterior columns chiefly preside over the motions of the body. The seat of those lesions of mobility will depend entirely upon the part of the spinal marrow that is inflamed. Hence they vary with the divisions we have just now established, as the cervical, dorsal, or lumbar portions of the chord become implicated. The faculty of motion, then, may be lost in the superior extremities; in the trunk and muscles of respiration; in the lower extremities. All these parts may be variously affected, and perhaps the only general principle we can lay down is, that the lesion of motility affects all parts of the muscular

system which receive their nerves from below the inflamed point of the spinal chord. All these parts, I say, may present various lesions of motility, such as convulsion, paralysis, contraction, &c.; there are, however, some exceptions to the general rule now laid down. Thus in the *Physiological Journal* of M. MAGENDIE, you will find a very remarkable case related: the cervical portion of the spinal marrow presented a considerable degree of ramollissement in its anterior columns; the upper extremities were paralyzed, but the lower limbs preserved the faculty of motion intact. Here, then, the influence of the disease was not propagated downwards.

A second general principle to be deduced from the cases of myelitis which we have observed ourselves, or which have been published by others, is, that when the inflammation commences in the lower portion of the chord, producing paralysis of the inferior half of the body, it has always a tendency to mount upwards: you will first observe a paralysis of the abdominal muscles: the chest next becomes affected; and, finally, the upper extremities lose their power of motion. This is a principle that you should remember, for it explains the trouble of respiration and other grave symptoms, that we often witness in the latter stages of myelitis.

We have now to inquire into the nature of those

Lesions of Motility

to which we have pointed, as the principal characteristic symptom in inflammation of the spinal chord. The muscular action may undergo various modifications, according to the seat and march of the disease, the lesions of motility being more or less marked according as the inflammation may take on an acute or a chronic form. In some patients we do not observe any true paralysis. The only modification of motility which they present is a certain weakness and loss of force in the extremities sometimes. Sometimes the paralysis attacks a single finger, then gains the rest in turn, and gradually ascends up the arm. Some patients complain of nothing but a feebleness when they would grasp any object, an incapability of executing their accustomed motions with energy. Others, again, are attacked with convulsive motions in some of the muscles. The paralysis may come on in a gradual manner, being preceded for months, even a year, by weakness in the limb; or, on the other hand, it may declare itself in a sudden and unexpected manner. This latter form is much more rare than the preceding, because chronic inflammation of the spinal marrow is a disease more frequently attended with than acute myelitis. In some cases the existence of inflammation in the vertebral canal is

spasmodic contraction of some of the muscles; at other times the symptoms are more slight; the patient is perhaps tormented with what are called *cramps*, and this may be the principal phenomenon for a great length of time. There are patients in whom inflammation of the spinal marrow declares itself by an attack of convulsions, and then we chiefly remark them in the acute stage. Sometimes these convulsive motions assume the character of chorea, and can be distinguished with difficulty from it; of this an example was published lately by an internic of the *Hopital des Enfants Malades*. Finally, tetanic symptoms may join themselves to the long catalogue of lesions of motility we have now laid before you. The cause of tetanus has without doubt often escaped the researches of the anatomist; but inflammation of the spinal marrow may give rise certainly to tetanus, as it sometimes does to chorea; the symptoms are then terrible, and the sufferings of the patient only terminate by his death.

Thus you see how various are the lesions of motility connected with inflammation of the spinal marrow; and here we might ask ourselves the question so often suggested by a review of cerebral diseases. "How comes it that the same lesion produces such a diversity of phenomena?" We have explained to you how many of the disorders accompanying this affection consist in lesions of the intelligence, or of movement; and we saw, in particular, how the latter function undergoes a great variety of modifications. Inflammation of the spinal marrow may also evince itself by

Lesions of Sensibility (in the neighbourhood of the Spine),

existing either alone, or accompanied by some other of the symptoms we have already pointed out; they exist chiefly when the posterior pillars of the spinal marrow are implicated, and this confirms what we have said in the last lecture on the experiments of MAGENDIE, BELL, and other physiologists, on the different functions of different parts of the chord. These lesions of sensibility may exist in the immediate vicinity of the spinal marrow, or may present themselves at various points of the body more or less removed. In the first case, that is, where the derangement of sensibility occupies the spinal region itself, we may observe a pain situate immediately over that point of the vertebral canal which corresponds to the inflamed portion of the spinal marrow; or, on the other hand, should the myelitis be general, comprising the whole length of the nervous pulp, we may feel a sensation of tenderness, passing into pain, from the top of the cervical vertebrae down to the loins. Thus you see the various degrees of sensibility shown by the tenderness of the skin

covering the vertebral spines, may be partial or general; the first being much more frequent than the latter, because inflammation is more frequently confined to a small portion of the chord, than diffused extensively through its mass.

In some cases, the pain which thus accompanies myelitis is increased by motion of the body; in others this is not the case; the movements are executed with freedom, and the only sign of lesion exists in a small portion of the canal, not discoverable unless pressure is exercised directly upon it. Sometimes the pain is singularly influenced by a change of position; there are patients to whom the horizontal posture is intolerable, and who cannot lie down without suffering a degree of pain which compels them constantly to observe an upright position.

Although the spinal marrow is deeply seated in the centre of a bony canal, and covered with a variety of parts, such as bone, ligament, muscular tissue, and skin, yet experience has established beyond all doubt, that during the existence of an acute or chronic myelitis, pressure made upon the spinous processes of the vertebrae may give rise to a greater or less degree of pain; this is a fact which is proved by frequent observation, though we cannot exactly explain how pressure can influence the sensibility of a part so deeply seated, and protected in so complete a manner.

The most ordinary method employed for establishing the existence or absence of this symptom is to run the finger downwards along the bony ridge formed by the spinous processes. When you come to a sensible point, there is the seat of the disease, and its extent may be estimated according to the limits of the painful integument; another method sometimes recommended by authors, is to dip a sponge in very warm water, and then pass it along the line of the spinous processes; when you arrive over the inflamed portion, the patient will evince signs of pain and uneasiness. I have had recourse to this method more than once, and did not find that it succeeded; there was no symptom whatever of pain, although the patient evidently laboured under an inflammatory affection of the chord, or its membranes; I therefore think it should be abandoned for the former, which is much more sure and satisfactory.

But before we go any further, let me hasten to warn you that the existence of pain upon pressure over some one point of the integuments covering the spinous processes of the vertebral canal, is far from being a certain indication of myelitis. We can never affirm the chord to be inflamed from this one symptom alone; the reason is evident. Reflect for a moment on the number and variety of parts submitted to pressure, when you run your finger along the spinal column in the manner just pointed out. An

affection of any one of these tissues may clearly give rise to painful sensations, and even the more readily as they are more superficial. Let us enumerate briefly these several parts. In the 1st place, commencing from within outwards, you have the fibrous tissue, and this you know is one frequently subject to rheumatic inflammations; hence the sensibility of the integuments may be nothing but a simple rheumatic pain. 2nd. Some one portion of the osseous canal may be diseased; the intervertebral cartilages may be ulcerated, the bodies of the vertebrae inflamed, the spinous processes themselves more or less extensively carious. In all these cases, pressure will necessarily produce more or less pain, without the nervous pulp being at all implicated in the malady. 3rdly. The symptom in question may depend upon a true neuralgia of the spinal marrow, a disease whose existence has been established upon authorities that we cannot contest; rachialgia then may produce tenderness along the dorsal region, though it differs essentially from inflammation; indeed, the pain by which it is accompanied is in general more severe and excruciating. Finally, the disease may be confined exclusively to the membranes of the chord, and the modification of sensibility which now occupies us, will, in that case, be connected with a lesion to which the substance of the chord itself may be a complete stranger.

Lesions of Sensibility in more distant parts.

So much for lesions of sensibility in the neighbourhood of the canal. In a second form we said the pains might occupy a distant portion of the body, the limbs, for example, the abdominal region, &c.; or may follow the trajects of the great nervous chord. This species of pain sometimes accompanies the disease through its whole course, and is constant; at other times it is intermitting, and does not affect the patient except at certain intervals. It plays a most important part in the history of myelitis, and requires to be investigated with more than common attention. In more than one case these pains in the limbs have imposed upon the physician, simulating in the closest manner a rheumatic affection, or other pains, and withdrawing his mind from the real source of the disease, to search after another that has no existence. You will find several examples of this, as we may call it, false rheumatism, in authors, where certain painful affections of the limbs were for a long period of time the only remarkable symptom; and where their subsequent termination in a dangerous disease indicated, though too late, the origin from which they were derived.

In certain cases the development of inflammation in the substance of the spinal marrow is preceded for a very considerable

length of time by acute inflammation of the limbs. This is a case to which we cannot too strongly direct your attention. Remember then that the principal affection may commence by sympathetic derangement of the sensibility in a distant part of the body; that this lesion may exist for a long period without any apparent connection with the chord; and finally, that inflammation of the nervous pulp may reveal itself by no other symptom than pains, more or less acute, in some one of the four members.

Let us now turn to a contrary case, viz., one in which we have

Myelitis accompanied by a Diminution of Sensibility.

not by a derangement, but by a diminution, or even a complete loss. In most examples that we meet with, the loss of sensibility is partial, commencing in a particular portion of the body, as for example, the fingers, and then gradually extending to the root of the body. But sometimes the whole surface is equally affected. We do not find any trace of sensibility on pinching the integuments all over the body. The lesion is here general; but observe a curious fact, one of those exceptional circumstances which present themselves so repeatedly in the study of nervous diseases, and which we are unable to explain upon any anatomical principle. Even when the loss of sensibility is, as we have said, general—when the whole body seems equally withdrawn from external impressions, you will sometimes find a few points of the integuments, perhaps a single line, in which the faculty of sensation still lingers, while all around is, as it were, dead. We have witnessed more than one case of this kind. It is a curious point in the history of myelitis; for how can we explain the fact that out of many parts supplied by the same nerves, receiving their nervous influence from the same portion of the spinal marrow, one remains perfectly insensible, while another, distant but a few inches, or even lines, conserves its power of perception intact. In a far greater number of cases, however, the lesion of sensibility is not so extensive; it may consist in a single engorgement, or numbness of certain parts of the body; this is chiefly seen in cases of chronic myelitis, when the patient experiences no modification of sensibility except in the upper extremities; the fingers, perhaps, are numb; the patient has a tingling sensation in the extremities; sometimes the whole arm is cold, or he is unable to warm himself, and complains constantly of a sensation of chilliness.

Thus you see how inflammation of the spinal marrow is accompanied by various symptoms of derangement in sensibility, motility, varying from a simple diminution of muscular power in certain parts, to a total annihilation of sensibility, and a

weakness, or the slightest shade of modified sensation. You saw, in our last lecture, how encephalitis gave rise to certain troubles of the function of nutrition. The same class of symptoms not infrequently accompanies inflammation of the spinal marrow; let us now turn to these, and first as regards

Doubles observed in the Organs of Digestion.

A certain number of cases of myelitis are characterized by a greater or less difficulty of deglutition: the patient is unable to swallow either liquid or solid aliment with facility, it is only after repeated and long-continued efforts that he can pass his food along the back of the mouth and pharynx. This phenomenon is more easily explained than many other derangements of the motile power which we observe during the course of a myelitis: it certainly is connected with paralysis of one or more of the muscles composing the pharynx and upper part of the œsophagus; hence arises derangement in the function of deglutition; hence is produced a symptom to which we would call your attention. Or it may sometimes simulate other diseases, and give rise to a complete error in the diagnosis. Thus you may have a patient labouring under many of the symptoms of angina, such as uneasiness about the throat, difficulty of swallowing, &c.; these phenomena may persist for a considerable time, and resist all the ordinary means, because they depend, not upon an inflammation of the mucous membrane of the pharynx, but in a true, chronic inflammation of the spinal marrow. I had occasion to see a very remarkable case of this kind, some time ago, at the *Maison Royale de Santé*; it was that of a female, in whom, long before the appearance of paralysis in the limbs, or any alteration of sensibility, we observed great difficulty of deglutition, with paralysis of the tongue; these were for some time absolutely the only symptoms which she presented; the disease, however, at last assumed a more rapid march, and soon carried off the patient. On examining the body, we found the cause of the symptoms just alluded to, not in the brain, but in the spinal marrow. We found all the anatomical characters of acute inflammation at the superior part of the chord, viz. great injection, with softening of the nervous substance. Here then was an explanation of the symptoms, for you all know that the nerves which go to the pharynx, and a portion of the lingual branches, are given off from this part of the spinal marrow, or at least from its immediate vicinity.

The fact which we have now cited is a curious one, and should put you on your guard against those partial lesions of motility which might seem insignificant, but which are followed by the most serious accidents. Mons. Four-

not communicated to me, a short time ago, a case exactly similar; there the cause of the injury was external, a considerable weight had fallen on the patient's back, and struck the upper part of the spinal column with some force; the individual was immediately seized with difficulty of deglutition, caused by paralysis of the muscles of the pharynx, and also, as in the former case, with paralysis of the tongue.

In some individuals we observe as derangement of the digestive functions, a set of symptoms which belong more peculiarly to encephalitis; we have vomiting, and this may even be the predominant symptom: in others, the small intestines are principally deranged; the patient is obstinately constipated, and we cannot obtain alvine evacuations, even by employing drastic purgatives. The difficulty of moving the bowels in tetanus is well known: does this depend on the spinal marrow being implicated in the disease?

If the Circulation be troubled,

then we may have general fever, with its ordinary phenomena; however, when the inflammation of the spinal marrow is not very extensive, the patient is usually free from fever; the skin remains cool, and the circulation is not accelerated beyond its normal standard. But the circulation becomes often deranged in a manner that cannot be attributed to febrile excitement. Mons. SERRES was the first who called our attention to this phenomenon, which is a very remarkable one. In some cases the patient is constantly tormented with more or less violent palpitations of the heart, and the trouble of this organ may even be carried to such a degree as to simulate closely aneurysm: we may, perhaps, explain this symptom by the direct action of the spinal marrow upon the heart, and the immediate communication between them; but however this may be, the fact is no less certain and worthy of attention. Some individuals, instead of palpitations, show a singular tendency to faint; I have an example of this now under treatment; it is that of a young lady who presents all the signs of inflammation of the spinal marrow; she is compelled to observe the most strict rest; whenever she moves, whenever the action of the spinal marrow in the production of voluntary movement is at all increased, the central organ of the circulation becomes immediately affected, and she falls into a state of weakness and fainting, from which nothing preserves her but an abstinence from all motion. Thus we have two species of derangement in the circulatory organs accompanying myelitis. One in the acute stage, the simple inflammatory fever, too well known to require any notice. The second species usually accompanies chronic inflammation of the chord, and declares itself either by palpitations and other irregular actions of the heart, or

by fainting and a momentary suspension of the circulation. Let us now examine

What influence is exercised on the Respiratory Organs in Myelitis.

We cannot doubt but that inflammation of the spinal marrow modifies this function in a considerable manner, especially when the inflammation occupies that portion of the chord from which the intercostal nerves are derived. When the disease is situated lower down, the patient may remain free from symptoms of dyspnoea for a length of time: this we can readily conceive; however, in almost all cases when the malady has been prolonged to any considerable period, the respiration becomes embarrassed, and, in virtue of a law which we laid down in a previous part of the lecture, every myelitis has a tendency to ascend from the lower portions of the spinal chord to the superior. In encephalitis, or inflammation of the brain, the pneumogastric nerve becomes implicated, and the respiratory functions are eventually deranged, from the trouble of innervation in the central organ of the nervous system. In myelitis, or inflammation of the spinal marrow, the circumstances are quite different. Here the influence is no longer cerebral, or nervous, but the immediate cause of dyspnoea resides in a diminution or loss of the mechanical powers which dilate the chest. The inflamed portion of the chord no longer stimulates the intercostal nerves; the muscles of the chest cease to act, and respiration is gradually extinguished. In some cases the diaphragm is chiefly affected. This important muscle is occasionally struck with paralysis, or ceases to act with its accustomed energy. In other cases the action of the muscles is inordinate. Finally, we sometimes have occasion to observe cases where the actions of the diaphragm instead of being performed with regularity, as in a state of health, become spasmodic, and the patient is distressed with a constant hiccup.

The definitive result of the various lesions of the respiratory organs which we have just enumerated, is to produce sooner or later a degree of asphyxia, under which the greater number of individuals who die from inflammation of the spinal marrow succumb. The influence, then, of myelitis on the respiratory functions is well established, and sometimes the first signs may be discovered long before the disease has sufficiently advanced to modify the motions of the chest. I will relate to you a case which I saw this summer:—A young man had suffered for a length of time from a fixed pain in the upper part of the cervical vertebrae: this was accompanied by a bruit de cracquement, whenever the region of the neck was submitted to examination. During the continuance of this pain in the region of the spinal marrow, he was subject from time to

time to attacks of dyspnoea, of the most violent character, which were sudden access of suffocation; which seemed immediately to threaten his existence: this lasted for a few minutes and then went off, to return again at an uncertain period. Upon examining this case with some attention, we thought the symptoms depended upon some disease situated in the articulation of the first cervical vertebra, giving rise from time to time to displacement and strong compression of the spinal marrow. You can understand that if the attacks of suffocation to which we now allude had continued during a long period, they might naturally enough have led one astray, and given rise to the idea of asthma; indeed, perhaps, we might not go too far, if we were to say, that certain species of this latter disease, which most authors regard as depending exclusively on an organic lesion of the heart or pulmonary tissues, might be traced to derangement in an organ far from either the respiratory or the circulating systems. It now remains for us to ask,

Are the Secretions modified in Myelitis?

Yes, certainly, inflammation of the spinal marrow does modify them, though not in any remarkable degree. You will find it very generally asserted in authors, that the vessels secreting the perspiration cease to act when the limb is paralyzed; in a word, that such portions of the body as have lost the power of motion do not perspire. This may sometimes be the case, but it is far from being a general rule. I have seen many cases which prove the contrary. There is another fluid which is modified, but merely in the mode of its excretion. Several patients affected with inflammation of the spinal marrow, cannot urinate well; however, observe that this does not depend upon any diminution or change in the secretion itself; the incapacity of urinating is here one of the phenomena of paralysis, and the secretion is retained because the bladder is unable to expel its contents. Having thus briefly noticed the modifications of secretion, we come to a question of great interest, and one which has given rise to considerable controversy, viz.,

How far are the Reproductive Organs influenced by the existence of Myelitis?

Here the facts upon which we can depend are very few: however, I may tell you, that I have seen a patient affected with acute pain along the dorsal region, with pains in the limbs, convulsive movements, and other similar signs of myelitis, in whom there existed at the same time a very considerable excitement of the genital organs, such as priapism, &c., and this confirms the arguments of certain physiologists, of the connection between the posterior part of the spinal marrow and the reproductive propensity and its organs. In

chronic myelitis an exactly opposite state has been observed, and the prolonged inflammation of the chord has here been known to bring on complete impotency. The facts to which we have just now alluded, and several others that we possess, are not to be neglected because they are not, perhaps, as complete as we could have desired: if we cannot derive from them any rigorous conclusions, they seem at all events to indicate that the spinal marrow is not altogether foreign to the normal accomplishment of copulation. In the female sex we also observe a certain number of facts that are worthy of attention. Thus authors relate that acute inflammation of the spinal marrow in pregnant women is accompanied by abortion. The nervous irritation gives rise to premature contraction of the uterus, which expels its contents before the period of maturity has arrived. In another form of myelitis, where there is little reaction, but a greater tendency to collapse, the uterus partakes in the general impression, is struck with inertia, and the accoucheur having in vain tried to stimulate it to contraction, is forced to have recourse to artificial means of delivery. However, these phenomena are far from being frequent or general. The premature expulsion of the foetus is by no means a necessary consequence of myelitis, and you will see many women who present the symptoms of myelitis in a well-marked manner, continuing to bear the fruit of conception without any derangement whatever in the organs of gestation.

The Diagnosis of Myelitis.

From the observations which we have now laid before you, you may perceive what a variety of symptoms accompany the development and march of inflammation of the spinal marrow, according to the nature, seat, intensity, and duration of the malady. Let us then pass to the diagnosis of myelitis.

On reflecting upon the numerous lesions of sensation and motion which successively present themselves during inflammation of the spinal marrow, you might think it an easy matter to form a correct diagnosis of the disease, and distinguish it from all other organic affections, but this is not the case. It is by no means easy to determine, in all cases, that the inflammation is situated in the marrow alone, or to discriminate its accompanying symptoms from certain analogous phenomena that occur in the course of other maladies. There are several circumstances which may lead you into error; let us hasten to point out the leading ones. In the first place, the osseous tissue composing the bodies of the vertebrae may be the part affected, and yet it may be impossible to apprehend the affection externally. Here, then, it requires the greatest attention, and no small degree of medical skill, to determine

whether the early symptoms depend on a true inflammation of the nervous pulp of the chord, or on a similar affection seated in the bony canal surrounding it.

There are cases where the phenomena of inflammation of the spinal chord are belied, if we may use the term, by other maladies of a different nature, where the functions of this part of the nervous system are notably deranged, without any trace of organic change existing after death. This is a fact upon which you may rely with certainty. I have seen many examples of it myself, and therefore speak with more confidence than if my assertions were founded upon the testimony of others. I have witnessed many cases in which paraplegia had existed for a considerable period of time, yet I was unable to discover any trace of organic lesion in the spinal marrow, although I examined the nervous substance, the membranes of the chord, and the bones which compose the canal, with the most scrupulous attention. It may seem strange that so grave a lesion of motility as paraplegia should exist for a length of time without leaving behind it any change of structure in the organ which regulates voluntary movement; but such, I repeat, is often the case. The same thing is seen in the brain. As we advance with the present course you will have occasion to see many other examples, and to convince yourselves that in nervous diseases the true cause of the functional disorder but too often escapes the researches of the most experienced anatomist. On the other hand, we have grave and extensive lesions of the brain, which declare themselves by no symptom whatever. We have cited cases of ramollissement, of suppuration, occupying a considerable portion of the nervous substance, and yet the phenomena of sensation and motion were absolutely unaffected. These cases deserve to be compared and contrasted with the former; they show the immense difficulties that surround us in every step we take in the study of nervous disorders, and point out the necessity of observing with minute care the most trivial points, in the hope of one day arriving at the solution of questions which at present are beyond our comprehension.

In numerous cases of myelitis the symptoms are so equivocal, so slightly marked, as to escape our notice altogether. In many other cases we have phenomena, which, however grave, we cannot attribute to any permanent organic change of structure. Thus we have seen an hysterical female who remained paraplegic for several days, and then suddenly recovered the use of her lower extremities. In other cases the patient becomes blind, or has an obstinate contraction of one or more limbs, and yet these symptoms will disappear more suddenly than they were produced. Again, look at the paralysis that sometimes accompanies

poisoning by lead, or what is called "colica pictorum." Here certainly we have no injury of the spinal marrow. In these, and many other cases, the lesion, whatever it may be, escapes discovery; it is in vain that you will seek to explain the functional derangement by an organic change. Unfortunate is he who obstinately persists in such a path. Truths that are familiar to others will escape his notice, or be rejected without examination; the search after a chimera will distract him from more solid pursuits; he will remain for ever at the portal of science; he may knock, but will never enter.

Dr. ESQUIROL relates a case in which the lower extremities were completely paralyzed during life, and what do you think he found on examination of the body? He found two cancerous masses occupying each anterior extremity of the cerebral hemisphere. Here, certainly, according to the received ideas, the lesion should have occupied some portion of the spinal marrow. This is a remarkable case; we find the brain usurping, as it were, the functions of the chord, and giving rise to a lesion of movement which is especially connected with diseases of this latter organ.

Another observation, equally worthy of attention, was published a short time ago in the bulletins of the *Anatomical Society*. Here the patient also suffered from paraplegia; the lower extremities were paralytic. On examination after death, the seat of the disease was naturally sought for in the spinal marrow; but the nervous substance was every where perfectly healthy. It was observed, in opening the body of the patient, that the bones were remarkably friable, and this led to further researches, which revealed the true seat of the disorder. The heads of both thigh-bones were completely destroyed, and hence the pseudo-paralysis, as we must call it, depended not upon a want of nervous influence, but on the simple circumstance that the limb was incapable of being moved, because the upper part would not stir. We merely notice this case to show, how necessary it is in medicine to observe everything with the strictest accuracy; for although pathological anatomy may not give the key to all the functional derangements that prevent themselves in the course of disease, yet we should never neglect to pursue it with ardour, and scrupulously examine every circumstance that may tend to throw light on their nature and causes.

Simulations of Myelitis.

In speaking of the diagnosis of myelitis, we mentioned that certain affections simulate in a very close manner diseases of the spinal chord: it is only within the last few years that this part of the subject has been studied in a regular manner, particularly in England and Germany, where

Messrs. GRIFFIN, TEALE, LABEL, HINTERBERGER, and ESS, have sought to generalize the facts which have been observed, and reduce them to certain principles. Let us enter into some details upon the subject, which is not without interest, especially as you will not find it touched upon in any of the works in your hands; indeed the subject is one new to myself, and I am indebted for my information to the analysis of the works of Messrs. GRIFFIN and ESS, published by the *Gazette Medicale*. If you wish to refer to these, you will find the analysis of Mr. GRIFFIN's work in No. 18 of the journal for 1835. The notice of Mr. ESS's was published a very short time ago in No. 46 of the same journal.* The gentlemen whose names we have just quoted, describe an

"Irritation" of the Spinal Marrow,

whose principal characteristic is to produce a symptomatic irritation in some other part or organ of the body. It is not inflammation, but a disease *sui generis*; in a word, what we call "irritation;" and leaves no trace of organic change after death. Let us see how they establish the existence of this malady. Suppose the patient is affected with palpitations of the heart, weight and constriction about the pericardial region; a feeling of suffocation, frequent nausea, fainting, &c.; they exercise pressure along the spine, and when they come to that portion of it which corresponds to the irritated part of the spinal marrow, they pretend that all the symptoms are aggravated by the pressure. When the stomach is the organ chiefly affected, pressure over the spine increases the nausea, the vomiting, the pyrosis, the pain in the hypochondriac region, and other signs of gastric irritation. If it be the head, the cephalalgia and nervous pains are considerably augmented. Whenever phenomena of this kind are witnessed, that is to say, whenever according to Dr. ESS "a sensibility of a greater or less portion of the spinal marrow to external pressure, coincides with a corresponding pain in some other organ, which we can augment at will by that pressure, the disease consists in an irritation of the spinal marrow, whose seat is indicated by the tenderness of the rachis." According to Mr. GRIFFIN, it is not necessary that any tenderness should exist over the region of the spine. If pressure excite pain in the distant organ, the point of the spine at which this phenomenon commences, is the part affected, although it may not itself be the seat of any lesion of sensibility.

All this may be very true, but it remains to be verified by further observation. I must confess that to me the idea of pre-

* Dr. ESS's paper is number 44, of *Bull's Magazin* for 1835.

ed upon a single part of the spine increasing, at will, ~~vomiting~~, ~~headache~~, or other disorders in a distant part of the body, especially when the spinal marrow does not exhibit any symptom of disease, — all this, I say, appears to me to partake a little of romance. However, we must examine the subject more carefully before we can judge. In medicine, facts are not to be rejected because they may seem a little extraordinary.

The observations of the same physicians tend to establish that a great number of neuralgic affections, attributed commonly to the fifth pair of nerves, really depend on the irritation of the spinal marrow now alluded to. This they establish in the way just alluded to. The patient has, perhaps, a pain in the superorbital region, in the jaw, &c.; pressure over the upper part of the cervical vertebra invariably augments this pain, if connected with spinal irritation; hence the true seat of the disease is to be sought in the spinal marrow, and not in the branches of the nerve, as we have been accustomed to think. In the chest, this affection may give rise to symptoms which simulate phthisis. A cough more or less obstinate is the most common symptom of irritation of the cervical portion of the spinal marrow. The respiration is often embarrassed; in some cases the patient has accessions of suffocation, always increased by pressure on the superior nerves. Many observations also show that several pains existing about the parietes of the chest, and mistaken for rheumatism, depend on this same "spinal irritation" of which we speak. This latter phenomenon is much more probable, and is consistent with what we know of the effects of chronic myelitis. A disease of common occurrence in practice, one that you will frequently meet in certain females, is neuralgia of the mamma; this affection they attribute in a great many cases to irritation of the spinal marrow, and we can admit it ourselves amongst the causes.

Again, Messrs. GRIFFIN and ENN speak of a peculiar pain in the region of the sternum, which is always aggravated by pressure over the spinous processes. Three days ago I had occasion to see a case that one would have been inclined to arrange under this class. A gentleman called upon me at my house for advice; the only symptoms he presented were, a well marked sense of tenderness in the skin covering the sternum, together with an habitual dyspnoea. I examined the pulmonary and circulating organs with care, and could discover no trace of disease. My head was just then full of the doctrines of Mr. GRIFFIN, and the fact that irritation could not, of course, ~~therefore~~ ~~passed~~ ~~my~~ ~~fingers~~ ~~upon~~ ~~the~~ ~~bone~~, ~~pressing~~ ~~upon~~ ~~the~~ ~~bone~~ might be modified; ~~how~~ ~~it~~ ~~occurred~~; how-

ever, the case I now mention is merely a negative fact, and proves nothing against the facts established by Messrs. ENN and GRIFFIN. In the abdomen this irritation may simulate several maladies, such as vomiting, colic, various diseases of the uterus, &c.; but as we said before, all this remains completely to be verified before we can admit it into the science: moreover, it is only an extension of the facts which we have noticed when speaking of myelitis and its symptoms. But it is probable that some forms of asthma may depend upon inflammation of the spinal marrow; yet there is still a vast distance between the two ideas. So much for the doctrine of "spinal irritation." Let us now resume the

History of Myelitis.

The duration of this disease is very variable; sometimes it may terminate in a few days; at other times it is prolonged for a considerable period, and may last for eight or ten years. It may terminate in a cure; but whenever inflammation of the spinal marrow is well marked, the disease is grave, and the prognosis unfavourable. In cases where death results, this latter termination may arrive in a different way: 1st. By extension of the inflammation upwards towards the brain: we have already noticed the tendency of myelitis to propagate itself upwards. 2nd. By extending to the respiratory organs, when the patient dies asphyxiated. 3rd. By implicating the heart; and 4th. Where none of these three organs is affected: the patient sinks gradually; he wastes away; the exposed parts of the body submitted to pressure ulcerate, and he dies in a state of complete exhaustion. A certain number of patients affected with acute inflammation of the spinal marrow go off in this way, without any of the great functions having been implicated during the course of the disease.

Treatment of Myelitis.

Upon this point we shall be very brief. The principles are exactly the same as for encephalitis. When accompanied by symptoms of reaction, you must take blood from the arm: if the fever be mild, you may content yourselves with an application of leeches or cupping-glasses along the spine, repeated according to circumstances. In cases of chronic myelitis, a good deal of reliance may be placed on cutaneous revulsives, particularly on moxa, or the cantry. Some physicians prefer applying douches before they act on the skin; while others direct their attention chiefly to the intestinal canal, and give purgatives, or laxative remedies, according to the patient's habit, or the object they may have in view.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE I.—DISEASES OF THE HIP-JOINT.

GENTLEMEN,—I intend to-day to address to you some observations on diseases of the joints. I have under my care at present many of those cases, and as the histories of several of them have been collected, I shall briefly relate the particulars, subsequently commenting on them, in order that you may trace the progress of diseases affecting the articulations so far as you are thus afforded the opportunity of doing so. Perhaps no subject in surgery is more important. They are productive of extreme distress to those who are the subjects of them, and the surgeon cannot be too careful in investigating them, and in distinguishing the means of cure. To four cases, in particular, I shall now direct your attention.

Case 1.—The first case is that of a patient with disease of the hip-joint. The hip is as frequently affected as any other joint, and perhaps its diseases are of more importance than the affections of any other joint. There is a man in Abraham's Ward, named Edward Carpenter, aged 56, from Bermondsey, who was admitted on the 8th of October, under my care. He stated that he had been regular in his habits, and that ten days previous to his admission, while lifting a sack of seed weighing about three hundred pounds, he experienced a sudden and severe pain in the left hip, extending to the loins, which obliged him to discontinue his work. On the following day, the pain still continuing, he obtained relief to some extent from cupping upon the buttock, according to the directions of a medical man to whom he applied. Pain in a short time was felt also in the knee, extending down the inner side of the leg, as far as the malleolus internus. Blisters were applied at this time, but without much benefit.

On admission he had a dull aching pain, principally situated at the anterior and inner part of the knee; and this pain was more particularly aggravated towards the evenings. Pressure on the groin produced severe pain. The left buttock was somewhat flattened. Pressure over the posterior part of the hip produced only trifling pain. Upon further investigation this limb appeared to be rather longer than the other: this seemed to arise chiefly from the obliquity of

the pelvis. There was a slight wasting of the limb. Every movement of the thigh produced some degree of pain. The pain of the knee was not increased by flexion or extension of the leg. The sleep was disturbed by the pain at night. His general health was pretty good.

I directed an occasional aperient to be given, of senna and salts, and ordered a moxa, of about the size of a shilling, to be applied to the left groin, about an inch to the outer side of the femoral vessels. I further ordered that he should have a grain of the acetate of morphia, with a view to allay the pain and to procure rest, and that he should keep his bed.

13. The report to-day was, that he had rested better at nights, and the pain of the knee somewhat diminished. The slough of the moxa, though partly, had not entirely, separated.—Next week the account was that he complained of pain on the inner side of the knee, extending down to the ankle. Pressure did not produce so much pain. The discharge from the moxa was trifling. I found at this time that he had been used to a certain quantity of stimulus, and as his general powers were failing, I directed that he should have a pint of porter daily, in addition to the medicine which had been ordered.

27. The moxa is discharging freely, and the pain is greatly relieved. He can move the limb without difficulty. The limb appears now to be of the same length as the other; sleeps well at night; the appetite and general secretions are good; bowels open.

30. He is not quite so well. The pain in the knee has become more severe. He has had but little rest at night, and the moxa has ceased to discharge. Probably that, and a change taking place in the weather just at this time, would account for the aggravation of symptoms.

November 3. Pain in the knee severe, particularly on the inner side. Pain in the hip, upon pressure on the anterior part, but not much when pressed posteriorly. I directed another moxa to be applied, in consequence of the aggravation of the symptoms, to be placed a little lower than, and anterior to, the first, which was a little more distant from the joint than I could have wished.

11. Up to this period he has been progressively recovering. The pain in the knee is but trifling, and pressure on the hip produces no pain. There is slight numbness down the inner side of the leg, but only very trifling symptoms remain to indicate any mischief in the joint.

Case 2.—Septimus C., aged 19, residing at [illegible], an intemperate habit, was admitted on the 8th of October, 1835. He stated that

about five months, whilst at work, he experienced a rather severe pain in the right knee, which obliged him to discontinue his labour for a time. His pain was relieved by rest, so as to enable him to resume his work; but he had not entirely got rid of it. In the course of the second day after he had returned to his work, the pain came on more severely in the knee, and he then applied for medical aid, and had blisters placed on the knee, but without any beneficial effect. On his admission, he complained of an aching pain on the anterior and inner part of the knee. I examined the hip-joint, and found that pressure on the groin produced pain; sudden abduction of the limb also produced pain. There was no appearance of the limb being longer than the other, but there was a little flattening of the buttock. As his tongue was not clean and his rest was disturbed, I gave him a small quantity of calomel with half a grain of opium; and the symptoms being trifling; I ordered an emplastrum lyttar to be placed on the groin.

14. The pain in the knee is somewhat relieved; he rests well at night; complains of headache. He was now ordered to repeat the blister, as the former had closed. I had only directed that it should be dressed with simple ointment, or a poultice. A week afterwards he had no pain, except on pressure being made over the anterior part of the hip-joint. But six days afterwards there was a relapse, and he complained of pain in the knee, particularly on the outer side of that joint. Pressure over the anterior surface of the hip-joint gave rise to pain. Any movement of the hip whatever, was attended with uneasiness. I now directed a moxa to be applied to the groin. At this time there was no indication of any disturbance of the general health. Still I have no doubt that that disturbance of the general health had commenced which was afterwards observed.

Nov. 3. Pressure increases the pain. He says he has a general numbness of the foot. It is now quite clear that he is labouring under the full effect of febrile irritation, having, as he states, caught cold.

4. He has still more general symptoms of fever; severe pain in the head; skin hot, tongue furred, bowels open, pulse quicker than usual, and he has a cough. He was now directed merely to take a little effervescent mixture.

5. Passed a bad night, and complains of great soreness about the epigastrium. He now took a dose of rhubarb and calomel, and was likewise ordered to take the house medicine, as the former did not act. A blister was ordered to be applied to the back, and a decoction of house medicine; the cough has been distressing; he has had

but little rest; the soreness of the epigastrium continues, but the skin is moist; pulse a little softer, and the tongue getting clean. In consequence of the cough and pain, I directed him to have some of the Dover's Powder, and to take a drachm of the spiritus aetheris nitrici, a drachm of the sirup of poppies, and ten drachms of the camphor mixture,—a medicine calculated to act in some degree as a diuretic, and also to keep the secretions of the skin and bowels a little excited. Next morning it was found that he had passed a better night, but he still complained of pain in the knee, which was increased upon any motion of the hip. Pressure over the anterior and inner part occasioned more pain. Twenty minims of Ipecacuanha Wine were now directed to be added to each dose of the medicine.

29. The rest is much disturbed by the pain in the knee, and the cough is very distressing. Yesterday there was a good deal of pain in the left hypogastric region. There is pain in the epigastrium. The breathing is rather hurried; pulse 84, and very compressible; skin cool, and bowels open. I directed that he should take a small quantity of mercurial medicine, and that there should be a blister applied over the left hypochondrium. This is the case as it presents itself at present; the local affection is aggravated, and the case is a good one as illustrative of points which I shall presently note.

Case 3.—The third case is one of chronic inflammation of the fibrous capsule of the hip-joint; it is the case of Thomas Lachey, aged 11, residing in the city, admitted October 7th, into Abraham's Ward. He states that about four months ago he experienced a sudden pain in the left knee, but from no particular cause of which he was aware, and that it always increased towards evening, and after taking exercise. For this he was admitted into *St. Bartholomew's Hospital*, when he had two issues placed upon the hip, just over the trochanter major. Those issues having relieved the pain, he was discharged as cured. In a short time, however, the pain returned with increased violence, and in about a week afterwards he was admitted into this hospital complaining of pain of the anterior part of the hip upon pressure over the trochanter major. Any motion of the joint increased the pain. His rest at night was disturbed, but his general health was pretty good. From the severity of the disease and its duration, I directed the moxa to be employed; and from the feebleness of the general powers, which were rather below par, I ordered that he should have some porter in addition to the ordinary diet of the house. The affected limb was longer than the other.

13. Very much relieved. The affected

limb is still a little longer than the opposite limb. Pressure produces slight pain.

21. The lengthening of the limb is but trifling; the pain has subsided, and he is much better.

29. I found he could walk without pain; there was now no lengthening of the limb; the left buttock had nearly regained its natural size, and he was on this day presented as cured.

Case 4.—The next case is one also of chronic inflammation of the fibrous capsule of the hip-joint. Sophia North, aged 26, a housemaid, living at Farnham, in Surrey, was admitted into Queen's Ward on September the 3rd. She states that about four months ago she received a blow on the left hip, from a fall. The part in a short time became swollen, and she experienced considerable pain in the joint, and also at the anterior and inner side of the knee. The pain was of a dull character, and disturbed her rest. Leeches and blisters were applied, and the blisters were kept open, but she derived no advantage from them. Upon her admission she complained of pain of the anterior and inner part of the knee. The pain in the hip was more severe than it had been, and was increased by pressure over the trochanter major. Her general health was much deranged. I ordered that a moxa should be applied over the trochanter major, which gave but little relief. I then directed that a second moxa should be applied to the groin, which relieved her considerably.

Oct. 4. There is less pain; she sleeps better at night; perspires towards morning; the left limb is nearly an inch longer than the right; the buttock on the affected side is flattened, and the general health is impaired.

13. Much improved. To take the decoction of sarsaparilla twice a day.

20. Little alteration.

24. Pain a little greater; passed rather a bad night; the limb apparently is somewhat smaller than it was upon her admission.

28. Pain rather severe, but it does not disturb her rest; there is evidence of additional weakness, from copious perspirations; the discharge from the moxa has ceased.

Nov. 5. Rests tolerably well at night, and the moxa is nearly healed.

11. Pain in the knee yesterday, and increased by the slightest motion of the hip-joint. No pain in the knee to day. Can bear pressure better on the posterior part of the hip, but when pressure is applied anteriorly, it produces some pain. I ordered that a second moxa should be applied.

Diagnosis, Pathology, and Treatment.—These cases all have reference to diseases of the same articulation, and three of them present very nearly the same symptoms. In the first case we find that inflammation was produced in the hip-joint by a violent strain.

We can account for this, when we know that the muscles of the thigh are attached to the fibrous capsule of the joint, their tendons being connected with the capsule itself; so that by violent exercise, such as raising a heavy weight, there might be laceration of the tendons of those muscles, and of the fibrous capsule itself—a very probable cause of such inflammation. We find the pain extending to the loins, probably from some slight strain of those parts, and not as being connected with injury to the hip. After inflammatory action had been set up, and simple means had failed to relieve the patient, he applied here, and we find that he had pain at the anterior and inner part of the knee. This pain is increased towards evening, and pressure produces an aggravation of it. Now, as to the situation of the pain, that is a point of importance. The fibrous capsule of the hip-joint is very extensive, but not so extensive as the mucous or the serous membranes. We know that in inflammation of the peritoneum, the pericardium, the pericranium, and so forth, inflammation extends very quickly along them. But if you take the capsular ligament of the joints, you will often find organic thickening taking place at one part of the ligament, while the other parts remain unaffected; and the pain of the anterior part of the joint denotes that the morbid affection is confined to that particular part. This is indicated by the sympathetic pain which affects the knee; and it is upon the anterior and inner part of the knee that the patient feels the pain. You can account for that by recollecting the anatomical structure, and the distribution of nerves to those parts;—the division of the anterior crural nerve, and the saphenus major and minor, one of which is continued to the foot, and the other is lost above the knee, on the inner and anterior side. It is of much importance to attend to this, because the closer in contact with the affected part that the remedies can be applied, the more likely are they to be of service. Frequently you will find that there has been an indiscriminate use of applications, or abstraction of blood, over the posterior part of the hip-joint. You generally find that blisters or moxa are applied there, which are not likely to do one-sixth of the degree of good that they will do if applied to the groin, near the seat of the disease. It becomes, therefore, of much importance to ascertain accurately the symptoms, and whence they proceed.

Next, there is flattening of the affected buttock. This is the case in all the patients. Taking a posterior view of the affected and the sound parts, from the loins to below the knees, you would see the flattening of the buttock on the affected side, and the division between the two parts, as if being lost. You can account for this obliquity of the pelvis, and account for

lengthening of the affected limb, the crista of the ilium of the sound side being an inch and a half higher than that of the affected side. As soon as the capsular ligament becomes affected, we have sympathetic affection of the knee, and sometimes sympathetic affection of the muscles at a great distance from the part which is the immediate seat of disease. The muscles of the leg become affected, so that its power is much diminished. The condition of the glutei muscles gives rise to this flattening of the buttock, when the patient is in an erect position, occasioned by the want of contraction that results from the adhesion of the integuments over the affected part. It is, therefore, from the loss of the natural power of the muscles to contract, that you have that appearance. On the sound side the proper muscular contraction takes place. The affected limb is frequently said to be longer than the other; but the fact is, that a person who is the subject of an affection of the hip is always endeavouring to relieve the affected side, and for that purpose he is continually throwing the weight of his body obliquely upon the sound side. The one crista ilii may be thrown an inch or an inch and a half higher than the other; and even if you put the patient into bed, in the recumbent position, you will still find a slight degree of difference in the length of the two limbs.

But there is another very important point to be noticed, which gives rise to the apparent lengthening of the affected limb, even when the patient is recumbent; and that is from the formation of the hip joint. The capsular ligament of the joint, which comes from the acetabulum, embraces, as you are aware, the head and neck of the thigh-bone, and owing to its construction this joint admits of motion in every direction,—abduction, adduction, flexion, extension, and I may say, every intermediate motion. We know that the capsule is longer than is absolutely necessary to retain the articular surfaces of the one bone in contact with the other; so that if you were to strip off the whole of the materials from the capsular ligament, you would find that you could draw the head of the femur from the acetabulum, to the extent of about an inch, or an inch and a half. The head of the femur, then, is kept against the acetabulum, in the healthy state, by the influence of the surrounding muscles. All the muscles which pass over the hip-joint have a greater or less influence of this kind, but more especially those which are immediately connected with the joint. Accordingly we find, that if, with forcible means, we pull the two legs, the healthy femur is still kept against the acetabulum, by the tension and influence of the muscles; whereas the separation of the diseased bone from the acetabulum increases the difference in the condition of the two limbs; and that may, as

I have said, admit of a difference in the length of the limbs, to the extent of an inch or more. This is a point referable also to an injury. A patient may have a fall; he may fall heavily upon the trochanter major, and be conveyed immediately to a surgeon, who examines the condition of the limb. The patient is placed in bed, and the surgeon, amongst other modes of examination, tries the length of the two limbs. He is surprised to find a difference of an inch or more in the length of the two; but then he finds that there is free motion of the joint of the affected limb, and not a great deal of uneasiness created by the movements. Now if he was not aware of what I have just mentioned, he might pursue his inquiries to satisfy himself whether there was not really a dislocation; but recollecting what I have stated, he is aware that this occurs from the result of the injury,—that the muscles lose their contracting power for a time, and, as a consequence, allow of the separation of the head of the femur from the acetabulum, upon the application of very slight force.

We have thus an explanation of the pain of the knee, of the flattening of the buttock, and of the apparent lengthening of the limb. We may also explain the diminished size of the affected limb. In the case of such an injury as I have alluded to, we know very well that the larger muscles, those which move the leg, lose their power, and when that is the case, there will be an apparent difference in the circumference of the two limbs, because all muscular fibres in a healthy condition have constantly a tendency to contract. Expose a muscle, or cut it through, as in amputation, and you will immediately observe that there is a strong disposition in the fibres to contract. By sympathetic influence, therefore, the muscles of an injured limb become flaccid, and lose their tendency to contract, therefore the diameter of such muscles will be different from that of sound muscles. There may be the same extent of muscle, but still, if you measure them, you will find that there is a difference in the diameters. However, after a time, or from disease, the muscles actually diminish in size; there is a diminution of the muscular fibres. This becomes very apparent in a case where the disease goes on to ulceration, or even to a more extended stage of disease.

We have seen in each of these cases, that the pain is increased in the knee on motion of the hip-joint, and not increased at all on motion of the knee-joint. These are important points for you to keep in mind. Again, you find, in the second case, that the patient described himself as having experienced an injury of the knee, and he spoke of the plan of treatment that was employed, as having been directed to the knee alone,—blisters and leeches,—but they did not afford relief. Now a surgeon should, in

such a case, immediately direct his attention to the hip-joint, where he would find the true source of the disease. But the point is easily settled in this way. If it be a pain in the knee, and resulting from disease in that joint, it will necessarily be increased by motion of that particular part of the limb. If, therefore, we find, upon putting the finger over the ligaments of the knee, or on pressing the synovial membrane, that the pain is not increased; or, again, if we flex or extend the leg, which may easily be done without moving the hip-joint, we discover that the motion does not increase the pain, then we must immediately look to the hip, knowing that sympathetic pain of the knee is almost the only symptom which indicates incipient disease of the hip-joint. So it was in the case I now allude to. Examination of the knee did not enable me to detect disease of the knee; I therefore proceeded to an examination of the hip, and a superficial examination of that joint enabled me at once to ascertain the disease was there. Again, the situation of the pain affecting the knee is not that which is the result of disease of the knee-joint itself. The pain which has been observed in most of these cases, has been of the anterior and inner part of the articulation; and we find that that denotes the situation of the disease to be of the capsule of the hip-joint, for each patient complained of pain in the knee. When pressure was made about an inch to the outer side of the femoral artery, over the situation of the capsule; but on all parts posterior to the trochanter major and tuberosity of the ischium, when pressure is made, you find they suffer but little. When the pain in the knee results from disease of the knee itself, you will detect that cause by pressure upon the knee, or motion of the knee-joint, as it will then arise from fibrous disease, or disease of the synovial membrane; you will appreciate this more distinctly from what I have to say by-and-by.

The pain in these cases being aggravated at night, is indicative of disease affecting the fibrous tissue. You see this very clearly in inflammation of the sclerotic coat of the eye. You can detect inflammation of this texture very readily, seeing that the surrounding structures are free from inflammatory action, it being alone the seat of disease: and when thus singly affected, we have symptoms, such as I have mentioned, indicative of inflammation of the fibrous capsule of the joint. The same is observable in inflammation of the pericardium, and the same in inflammation of all the fibrous tissues. The patient is perhaps well in the day, but towards morning or evening the pain is greatly aggravated. It is a kind of intermitting pain, of a dull, aching, but not lacerating or lacerating character; quite sufficient, however, to disturb the rest, and to produce exhaustion in that way. Such, then,

is the rationale of the present symptoms, so far as we have tried to illustrate the form of the disease from the descriptions I have given; that is to say, the symptoms I have been relating, point out the situation of the disease and the particular texture affected.

Now as regards the treatment adopted in these instances. We may know, from the observation of circumstances which I shall relate in connection with other cases, that the disease has not extended to the synovial membranes, nor to the cartilages; that it has not extended so as to produce ulceration or disorganization of those parts, but consists simply of slow inflammation of the fibrous tissues, therefore the remedies to be employed are not of a severe kind, constitutionally, nor very much so locally. In the first place we ought to ascertain whether the disease is connected with, or dependent upon, any peculiar condition of the system. We find in most of the cases before us, that the general health is good; there is only one case out of the four related, in which the state of the general system influenced the disease. In two of the others the patients became a little exhausted, perhaps from confinement to bed, and the discharges from the bowels. I was induced from this circumstance to give them a quantity of such stimuli as they had been used to. But as to the local applications, or management, the first, and perhaps, the most important object is, that the patients should be kept at rest. They will find out the position which is most comfortable for themselves. Usually their comfort is increased by having some support under the ham; a small pillow, for instance, between the ham and the bed, and keeping the limb flexed. They will themselves move the pillow as they move the position of the limb. It is not necessary to confine or restrain the motions of the joint entirely. Merely moving the limb in bed may be sufficient for the comfort of the patient, and not likely injuriously to influence the disease. We find that the best mode of relieving the inflammation of the fibrous tissue, which is generally a sub-acute disease, is by resorting to counter-irritation; and we know that counter-irritation to a distant part from that which is affected, and to which you can make no immediate application, is often productive of good. For instance, we find blistering the head or neck in diseases of the brain, productive of beneficial results. So in pneumonia, or inflammation of the pleura, we find blistering the chest do good. Again, blistering the abdomen in peritonitis, or even in enteritis, is advantageous. So that applying counter-irritation to distant parts has a good effect as regards the diminution of the disease, wherever it is; but it is always better, wherever you can, to apply counter-irritant as near as possible. This is the case as possible. This is the case as possible.

area of inflammation of the brain, or of the membranes of the brain. A blister applied to the surface of the back is infinitely more effectual than one applied to the nape of the neck. Again, if we apply a blister to the anterior part of the chest, where the parietes are thin, we effect more good than by applying it posteriorly, where the parts are very thick.

I have directed your attention to the situation of the pain in these cases. If the pain be in the anterior part of the knee, you will find the disease to be at the anterior part of the capsule of the hip joint. If it be in the ham, the patient will experience more pain behind the trochanter; and in such a case, instead of employing the moxa, as we have done in all these cases, in the groin, I should apply them on the posterior part, between the trochanter and the tuberosity of the ischium, over the posterior surface of the capsule of the hip.

When the symptoms are very slight, I have often found a blister on the surface produce all the effects to be wished for, combined with attention to the secretions, and rest. If the disease, however, has been of longer duration, and you have reason to suppose it has proceeded to some extent in the fibrous tissue, it is better to resort to the more severe remedy of the moxa. The moxa is the description of counter-irritation which we now usually employ, and a very good mode of exciting counter-irritation it is. I have known patients who have had the moxa applied, and have had issues formed by nitric acid and by potassa fusa, who have given the preference to the moxa, though one might be disposed in the first instance to say that they would rather object to the moxa, and be content with the other. Still, any of these will have the same beneficial effect.

It is not my practice here, and this is the result of experience, to keep the moxa open by the use of any extraneous matter, so as to form what is usually denominated an issue; nor to keep a blister open. The cases I have related are, three of them those of adults, and one the case of a boy; but this is a very common disease at an early period of life, more common than at a more advanced age. Children at the age of two or three years, immediately on beginning to make progression up to the age of puberty, show a disposition to the setting-up of such disease. In such children it is not an uncommon practice to employ a perpetual blister, as it is called. A blister is applied, the cuticle is raised, and then an ointment, composed of the savine ointment and unguentum lyttæ, is applied to it, morning, noon, and night, for the purpose of exciting a discharge. A discharge is produced in that way, but greatly at the expense of the patient. The irritation produced by the moxa, is such as to

make a greater call upon the constitution than the pain which previously existed from the disease, and therefore weakens the patient most amazingly. I have found that in such cases a repetition of blisters is infinitely better than keeping one perpetually open. If it be a disease that will not yield to a blister, or a repetition of blisters, it is better to employ the moxa, as the irritation of the moxa is not attended with pain, nor does it make the same call on nature that a large blister does, which is kept continually open.

The same reason I have against the continuation of an open blister, is applicable to the continuation of an issue; for if in the case of an issue you use beads, or beans, or peas, there is a great drain on the constitution, a great irritation kept up, and, in fact, an aggravation of the disease. In the ordinary cases, such as I have detailed to you to-day, the use of the simple moxa, allowed to heal, and then applying it again, if need be, is much better than introducing any extraneous matter for the purpose of keeping it continually open. It throws off a slough, and yields a certain discharge, which is as much as these cases require, independent of attention to the secretions, and any other necessary local treatment.

In one or two of the cases we have had, we have thought it necessary to procure rest by artificial means, by morphia or opium. The quiet produced in that way is favourable to the restoration of the natural state; and your medicines or local remedies have a much better opportunity of doing good if the patient be kept quiet, than they have where the rest is disturbed, which it usually is from his sufferings.

The treatment, so far as regards these cases, has been beneficial; one case has been presented cured, and two of the others may be considered as convalescent.

In one of the cases which I read to you, we find that the cure has been interrupted by general disturbance. The patient, as he states, caught cold, and has got rather a severe febrile disease upon him. You must suppose that sometimes local disease becomes aggravated during the prevalence of fever, which is not connected with it. This is the case here. The fever is not sympathetic, but it has been induced by cold, and therefore induced by a cause which is entirely independent of the disease for which the patient came in. The fever, however, has had its influence on the local disease; the boy is not strong, he is rather of a scrofulous habit, and the general powers have been lessened by this attack on the general system; the consequence is, that the local affection has become aggravated, and will continue so till we have subdued the febrile symptoms, and rallied the general powers, by appropriate remedies. At present he is under the influence of such remedies, merely,

as are calculated to check the influence of the fever; he is not in a situation to bear tonics, but as soon as he is they will be given, and you will find the local symptoms will again be subdued after the fever has been overcome, and he is restored to better health.

I am afraid the time will not allow me at present to go into the other cases, but they will be more valuable for observation hereafter, as they will then show more of the process of cure.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON A CASE OF

CHRONIC GASTRITIS.

Delivered in the Session 1835-36.

By DR. ROOTS.

The first case, of which I shall now speak, gentlemen, is a case of chronic or sub-acute gastritis occurring in Luke's Ward, in the person of Henry Free, who was admitted on the 1st of October. He was thirty years of age, and by trade a hatter, and he stated that he had drunk very freely of spirits, chiefly of rum, but that he had been generally healthy up to about three weeks before his coming into the hospital, when, after a long walk, and getting into a state of perspiration, he was seized with shivering, followed by heat and sweating, with pain, swelling, heat, and redness of the right leg. This swelling of the leg it appears was treated by incisions and fomentations. He took at the same time, according to his account, some aperient medicine, and under this plan of treatment he appeared, or at least the leg appeared, to have rapidly recovered. As the leg got better he began to complain of sickness, more especially after taking food, which sickness was attended with some degree of tenderness about the epigastrium, and a sensation of burning heat at the back of the throat and fauces. These symptoms he found were very much increased by taking any stimulant into the stomach. The gastric symptoms had gradually increased in intensity up to the time of his admission, and then he complained of severe paroxysms of hiccup, occurring every five or ten minutes, attended with pain in the epigastrium, and occasionally by the ejection of a clear fluid, of a bitter and saline taste. He also complained of considerable burning sensation along the whole course of the oesophagus up to the back part of the pharynx,

with great tenderness after taking food, frequent eructations, and sometimes vomiting. This case was taken, as I am detailing it to you, by the clinical clerk, who states that there was some degree of tenderness over the region of the stomach. His appetite was bad; he slept badly, on account of the hiccup, which disturbed him very much during the night; pulse 94, rather sharp and hard; his bowels were usually moved once a day; the tongue was morbidly red over the whole surface, having on some parts aphthous points, and in others small, irregular, and irritable ulcers.

Now, when I myself examined him, I found that there was not only considerable tenderness on pressure at the epigastrium, but increase of heat there, and the man was considerably emaciated. He was directed, therefore, to be bled to the amount of ten ounces, to take two minims of hydrocyanic acid, and half an ounce of mucilage, in half an ounce of plain water, every four hours. The diet to consist of arrow-root and water, and sago and water.

3. The report of this day states that the blood was much buffed and cupped; pain and heat in the stomach somewhat diminished, as was also the hiccup; still sufficient hiccup, however, to prevent much sleep. Still, also, pain at the epigastrium, though it was considerably diminished. Aphthae and ulcers of the tongue less irritable; pulse now ninety, and softer, the bowels open, the motions dark.

5. No hiccup since the evening of the 3rd, but he still complains of a burning sensation extending up the throat, and he yet has acid eructation after food. Still tenderness, also, over the epigastrium; tongue not quite so red; the small aphthous spots have nearly disappeared, and the ulcerations are looking more healthy. Bowels generally open every day, pulse 94 again, and rather sharp and hard.

6. I saw him again to-day, and directed twenty-four leeches to the pit of the stomach, and ten grains of the carbonate of soda to be added to each dose of his medicine, — the hydrocyanic acid and mucilage. As I did not think his bowels were sufficiently opened, and as I did not like to order aperient medicine, I directed that a common injection of gruel should be thrown into the bowels, night and morning.

7. Much better since the leeches were applied; no more rising in the throat, and the sensation of heat has nearly subsided. No hiccup since; tenderness over the epigastrium much less; the aphthous spots on the tongue have disappeared, and the ulcers are cicatrizing. His bowels have been opened by injections every morning, and the motions were free.

9. Still improving. The burning sensation and tenderness at the back part of the pharynx, and the burning sensation along the whole course of the oesophagus, are much lessened.

I thought, some degree of heat, I directed eighteen more to be applied.

10. The leeches have relieved the tenderness considerably. There is no hiccup, no uneasiness after food, and no acid eructation; tongue much more healthy, and the ulcers cicatrizing; bowels have been opened twice very copiously; the two motions contained a little blood, the result, apparently, of some little irritation occasioned by the injection pipe. Pulse 96, rather small, but still accompanied by some degree of sharpness. He was directed in consequence of the little bleeding, and as his bowels were sufficiently open, to omit the injection.

12. The affection of the stomach much relieved; appetite much better; no tenderness over the epigastrium, and no further uneasiness after taking food. But at this time the left ankle became swollen and painful, and somewhat hot and red. A dozen and a half of leeches were consequently applied there, and afterwards the liquor plumbi subacetatis dilutus was constantly employed, with directions that he should take in the morning half an ounce of castor oil, and on the 13th the swelling, and tenderness, and heat, had in a great measure subsided. On the 16th he was still more improved, and he was directed to take his medicine only three times a day. This on the 15th was reduced to twice a day, with an occasional dose of castor oil. There is no uneasiness of stomach, no heat of throat, no sickness, no acid eructation after food; the appetite much improved; getting quite well; pulse 85, rather small, but quick. On the 20th he was nearly quite well, but as there seemed to be some degree of debility about him, I directed two grains of sulphate of quinine to be taken twice a day. On the 23rd he was ordered some beef tea.

27. Being now perfectly well, he was presented, with, I should say, no disease remaining.

Now this was a very plain straight-forward case. The man was clearly suffering under chronic or sub-acute inflammation of the mucous tissue of the stomach. There are two forms of the disease, the acute and the sub-acute, or chronic. The acute form is not, I believe, very frequently met with. I have only seen two examples of pure acute inflammation of the mucous tissue of the stomach since I have been in practice. One of these occurred in a young lady the near relative of a medical gentleman at Camden-town. The disease ran its course and proved fatal. The other was the case of a poor man in Somers-town to whom I was called in the latter stage, and which supervened on a severe attack of English cholera some days ago. The post-mortem examinations of these cases proved them to be acute inflammation of the mucous tissue of the stomach. The disease does not often oc-

cur in the acute form, we frequently meet with the affection in the sub-acute or chronic form; and the disease advances so slowly, that it may be readily overlooked, and only discovered when the mischief is beyond relief. Generally speaking, however, strict attention to the symptoms will enable you to detect it when it does exist.

The ordinary termination of the chronic form is generally in ulceration, or thickening, or softening, of the mucous and sub-mucous tissues. The ulceration may consist either in a considerable number of minute ulcers, or in one of considerable size, affecting either the mucous tissue or the follicular glands of the stomach. As the process of ulceration goes on, the surrounding parts thicken, and, ultimately, perhaps the ulceration extends through the sub-mucous to the muscular tissue, spreading even to the serous tissue; and if inflammatory action have not existed to a sufficient degree to excite adhesion to some neighbouring organ, the ulceration may extend through the peritoneal coat, and allow extravasation of the contents of the stomach into the abdominal cavity. Many such instances of the progress of ulceration, from the chronic inflammation, have occurred, without previous suspicion that such a condition of the stomach existed. Such extravasation would set up acute inflammation of the peritoneum of the abdomen generally. Sometimes, however, nature prevents this by adhesion to the liver, the spleen, or sometimes the colon; still of course the disease will ultimately prove fatal, though without extravasation.

The ordinary symptoms of chronic inflammation of the stomach are, a feeling of heat extending from the stomach along the oesophagus to the pharynx; thirst, diminished appetite, nausea, and vomiting. Commonly, also, I believe, you will find tenderness on pressure at the epigastrium, sometimes, as in the case I have read, of a severe character, but the inflammatory action may be of so low a character as necessarily to be accompanied by increase of heat not sensible to the touch.

In the early stage, the symptoms are very often only those which are common to dyspepsia. I do not, of course, admit the existence of such a disease of itself as dyspepsia, difficult digestion. In point of fact, that must be dependent upon some cause, or a variety of causes, often, in different cases; but we understand commonly by the term dyspepsia, functional derangement of the stomach, unaccompanied by inflammatory action, or by any change in the tissues. Let us see, however, what are the ordinary symptoms of dyspepsia, and you will find how nearly they approach to those of chronic inflammation of the stomach. You often have great acidity, eructations, flatulence, and oppression after taking food, frequently with some

degree of pain in the stomach. These are common to chronic inflammation of the stomach, in which, very often, the patient complains only of pain after taking food,—that pain, too, frequently ceasing entirely as digestion is completed, the patient in many instances saying to you, “I am quite well; I only know that I am hungry; I take my food; I only know that I am ill for such a time after taking food.” In other cases the pain is much more prominent, extending often to the back from the stomach. Again, however, I would impress on you, that actual pain, unless you use pressure, is frequently denied, though patients will confess that there is a sensation of weight or oppression about the stomach; and occasionally you will find all these symptoms attended by pyrosis,—by the ejection of a clear, sometimes viscid, sometimes quite thin fluid, to the amount of from half an ounce to an ounce and a half, sometimes tasteless, sometimes acid, and sometimes both acid and bitter. Generally, however, as the disease advances, the symptoms become more urgent; the heat in the stomach is more distressing, the countenance becomes pallid and anxious, the vomiting more frequent, and occurring after every ingesta. The pulse at the same time is generally small, sharp, and occasionally accompanied by some degree of hardness. The tongue also most commonly exhibits some evidence of the disease. I say *most commonly*, because the tongue is not *always* a faithful indicator of inflammation of the mucous membrane of the stomach, though generally it is red nearly all over,—very often white at the back and centre, but morbidly red at the point and the edges,—sometimes covered by small aphthae, and, as in the case related, by minute ulcerations also. But I again urge upon you, that you must not, because the tongue appears natural or white, conclude that gastritis does not exist. I have seen several examples of well-marked gastritis, where there was nothing in the tongue to indicate that fact. Generally, however, it is a tolerably good guide.

As to the causes of chronic gastritis, abuse of diet, eating imperfectly-digestible substances, the abuse of spirituous liquors, and protracted errors in diet, are all likely to be exciting causes. Suddenly drinking a large quantity of cold fluid, the surface of the body, perhaps, being much heated, or, more likely, the nervous system being much exhausted, has been not an unfrequent cause of inflammation of the stomach.

With respect to your diagnosis, it is probable that you will understand all that I wish you to comprehend on this subject, by going at once to the treatment. In inflammation of an organ so essential to life, antiphlogistic measures must invariably be employed, both in the acute and in the sub-acute or chronic form of the disease. Bleed-

ing, generally and locally, are measures of primary importance, whether there is much activity in the inflammation. Never hesitate in such a case to take blood from the arm; let nothing prevent your doing that, unless you are satisfied that the disease has been prolonged to such an extent that the powers of the patient will not justify that measure. Depend on it also, that you will be much more likely (I speak now of the sub-acute form) speedily to subdue the inflammatory action by one or two general bleedings, than by relying upon local bleedings alone, and more especially where vomiting is urgent. You will remember, that with respect to the man whose case I have related, I did not hesitate to take blood from his arm, and that it was bled and cupped, and that the symptoms were thus somewhat relieved, the venesection not being required to be repeated. The subsequent application of leeches freely to the epigastrium was sufficient. But if the symptoms had not given way, if the vomiting, the hiccup, the heat of the stomach, had continued to be as urgent as before, I should have directed a second, perhaps a third, and perhaps a fourth abstraction of blood from the arm, before I began to rely on leeches alone.

In conjunction with bleeding, you will find counter-irritation of considerable advantage, but to this I would not resort until the activity of the inflammation was much diminished by general or local depletion. There can be no objection to occasional mustard cataplasms, because these leave spaces perfectly free for the renewed application of leeches. Therefore if you suspect that you shall have frequently to repeat the leeches, do not apply a blister; leave that until you feel pretty certain that you will not have speedily to reapply leeches. Do not understand me to coincide with some who I know have imagined that the inflammatory action of the mucous membrane of the stomach may be increased by a blister. I have never seen any such effect. In treating chronic inflammation of the mucous tissue of the stomach or bowels, I have, almost invariably, during some stage of the treatment, used blisters, and without ever having had occasion to regret their adoption.

As to medicines, if the vomiting be urgent, and there is much irritability of the stomach, I believe that the best thing you can give is the hydrocyanic acid, in doses of from one to two minims every two, three, or four hours, or even less frequently, according to the urgency of the vomiting. I believe, too, that it is useful to combine the hydrocyanic acid, as I did in this case, with some mucilaginous substance. *Cham water* is a nice soft application to the inflamed surface. The aphthae about the tongue and

ceedingly distressing, and a little gum water will often allay the irritation.

If I can possibly do without purgatives, more especially the nearer the inflammation approaches to the acute form, I rather abstain from them in the early stage, confining myself to the use of injections; but if obstinate constipation takes place, and the injections are not sufficient to produce what you may think requisite, then I would suggest, as the best purgative by the mouth, some castor oil. Too frequently, however, that will not be retained, and if so I should prefer a full dose of calomel, combined, perhaps, with a grain of opium; not, however, giving mercury with the slightest idea of its producing a beneficial effect on the inflammation of the mucous tissue. This, I am quite sure, from experience, would increase it; and I would also advise you to avoid opium if possible, because it only tends to produce greater constipation, and when it is simple inflammation, rather aggravates that condition. The hiccup (the diaphragm sympathizing with the stomach) is sometimes very distressing, and you may occasionally be driven to the exhibition of opium, but I am quite sure that you can only give it, with propriety, as a means of deriving a temporary respite from the distressing effects of the hiccup, which it is far better to endeavour to lessen, indirectly, by diminishing the inflammation of the stomach. But supposing opium seems to be absolutely necessary; then, before giving it by the stomach, I would prefer throwing it into the rectum, in the form of injection, thirty, forty, or even fifty minims, in a small quantity of starch or gruel.

You will remember, too, that during the early part of my treatment in the case of this man, on the second or third day—I added to each dose of the hydrocyanic acid and mucilage, ten grains of carbonate of soda. The acid eructations appear to be caused by a morbid secretion from the mucous and follicular glands, and which secretion, unneutralised, becomes an additional source of irritation in the stomach. The carbonate of soda, then, was given for its chemical effect, and its exhibition was attended with advantage.

The diet under such circumstances cannot be too simple. Chylification is evidently very imperfectly performed, and it would be absurd to task the stomach with food in large quantities. Nature would soon show the impropriety of it by vomiting the ingesta, with an increase of all the distressing symptoms. If the inflammation be very urgent, nothing but a little cold water should be given, or perhaps the best thing would be a small lump of ice placed in the mouth, to be thus slowly dissolved, and allowed to trickle down the stomach. The patient I am generally deriving great relief from the reduction in this manner, of the heat which

extends from the stomach into the pharynx. Plain cold drinks, in fact, are most grateful, though, if the symptoms be less urgent, there is no objection to allowing the patient, as I did in this case, a small quantity of arrow-root, or sago, in water. Every stimulant ought to be most carefully avoided. This man himself stated, that everything he took that was "strong," meaning beer or spirits, aggravated his symptoms. You will find it of great importance to attend to this in private practice. You will frequently be called to cases which will puzzle you to decide whether they really arise from some slow and insidious inflammatory action in the mucous tissue of the stomach, or are merely the result of functional derangement, brought on probably by some intemperance in eating or drinking. Take it as a rule, in which you can never err, that if there is much heat of stomach, much tenderness in the epigastric region, and, more especially, an increase of heat there on pressure, you will be right in treating the case antiphlogistically, immediately debarring your patient from every stimulating article of drink and food, and applying leeches to the pit of the stomach, or if the pulse warrants it, abstracting blood from the arm. Supposing that you commit an error in diagnosis, and that it is only functional derangement (and I admit that sometimes it is difficult accurately to distinguish), you can do your patient no harm by the restriction of his regimen, the application of a few leeches, and employing counter-irritation; but you may do infinite mischief, under the idea of the case being merely one of a weak condition of the stomach, by giving stimulants, and tonics, prescribing carbonate of ammonia, allowing brandy-and-water, advising an increase in the daily quantity of his wine, and permitting him to live a little more "generously."

There was another case admitted at about the same time, in Anne's Ward, which I did not designate as *gastritis chronica*, but as *vomitus-cum-hysteria*, because I did not believe, though some of the symptoms were present, that it arose from actual inflammation in the stomach. I rather ascribed it to that peculiar irritation of the stomach which we often see in hysterical females; and the mode of treatment pursued, verified, I think, the diagnosis. As considerable pain was complained of (though there was no increase of external heat), upon pressure of the epigastrium, I thought it right to apply some leeches, two or three times, and afterwards a blister. There was here some slight degree of redness at the point and edges of the tongue, but much less than in the man, therefore, as a precautionary measure, I applied the leeches; but I found, after a time, that there existed so much of that peculiar morbid condition of the sentient extremities of the nerves, which almost universally accom-

panies hysteria, that the same degree of tenderness was complained of on pressure over the whole of the abdominal and thoracic regions. Considering, however, that there might be some insidious inflammation going on, which this would be the best means of relieving, I applied the leeches, knowing that the loss of a small quantity of blood could do no harm to a girl in her condition. But the next day, believing that there could be no inflammatory action in the stomach, I ordered her some creosote, which, upon increasing the dose from one minim to three, speedily allayed the irritability of the stomach. This quite convinced me that the disease could not be of an inflammatory nature, because I never yet saw creosote taken into the stomach where there was any thing like inflammation existing, without its producing either increase of vomiting, or increase of pain, or heat in the stomach, speedily after it had been taken. I was, in fact, confirmed in my original opinion, that this was a case of hysterical vomiting. I may allude to it again, in order to say a few words with respect to the advantage of creosote—at least, to the degree of advantage which I have myself found in its use—in gastric affections.

HOPITAL DES ENFANS MALADES, PARIS.

RESEARCHES INTO THE DISEASES OF CHILDREN,

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY.*

TUBERCULAR MENINGITIS.

Child five years of age, of scrofulous constitution; sudden disappearance of an old affection of the scalp; for the two succeeding months headache, retching by irregular accessions; dulness; diminution of the intellectual faculties, and of motility; alternation of diarrhoea and constipation; pain in the abdomen; gradual wasting, and then constant headache, vomiting, followed by stupor, and incomplete paralysis of the limbs on the right side of the body.—Leeches behind the ears and to the temples; blisters to the neck and lower extremities.—Death; tubercular infiltration of some portion of the pia mater; granulations beneath the arachnoid, the plexus, and the peritoneum.

CASE.—Anne Camusat, five years of age, was transported to the hospital, from the Rue d'Angoulême, on the 30th of April, 1835. The parents of the young child, who themselves enjoy excellent health, and do not labour under any tubercular affection, inform us that she has never had convul-

sions during her infancy, and that she has been subject to placid swellings of the neck, eruptions of the scalp, and ophthalmia. About two months ago a suppurative of the scalp, which had existed for the last two years, disappeared suddenly, and since that period the child has frequently complained of pain in the head; she has become dull, apathetic, and ceasing to take pleasure in the amusements of her age. At the same period she experienced pain in the abdomen, was alternately constipated and affected with diarrhoea, and became gradually thin, a circumstance attributed to jealousy; during the three first weeks of the month of April the child coughed a good deal, but the cough has disappeared within a few days.

April 29th. Constant headache; the prostration is more marked than for last few days; appetite diminished; on the 30th bilious vomitings.

May 1. We found the patient in the following condition:—Face pale and thin; answers only by monosyllables to the questions put to her, and points to the frontal region as the seat of the pain; the eyelids are closed, and the patient avoids the light; she cannot maintain the upright posture, but can raise up the limbs freely enough; the latter do not present any spasmodic movements; the sensibility of the skin is not remarkable, and is equal on both sides of the body; pupils normal; the sight is weakened, but still preserved; the face exhibits alternations of paleness and redness; the skin is moderately warm; pulse 72, intermittent; the respiration is slow and unequal, 16 in the minute; the tongue moist, covered with a slight whitish fur; the vomiting has not returned since the 30th; tumefaction and tenderness of the abdomen; constipation for the last four days.

From a consideration of the patient's history, and the ensemble of the symptoms which presented themselves, viz. frontal cephalalgia, sensibility to light, slowness and unwillingness to answer, the stupidity, the diminished sensibility of the integuments, the slowness and irregularity of the pulse and respiration, the constipation, &c. we ventured upon diagnosing "a meningitis." However, the existence of this affection seemed doubtful to the physician of the hospital, who contented himself with ordering an *infusion of mallows*, and a *poultice to the abdomen*.

During the day the dulness and tendency to sleep persisted; these were interrupted in the evening by low cries; the alternations of flushing and paleness were now well marked.

May 2. Same sleepiness as before, no answers to the questions we address; eyes fixed; conjunctivæ injected; sensibility of the skin obtuse; movement of the limbs very strongly before we can reach them; pulse 60; respiration 20; constipation persists; urine

* The present paper forms a continuation of the cases and remarks which appeared at pages 429 and 430 of the present volumes of THE LANCET, under the above title.

sion of urine involuntary. (*A blister to each leg.*) During the day and night the patient did not articulate a single word, or put forth a single cry; she does not seem to be conscious of what passes around her; and from time to time is affected with a trismus which prevents the introduction of fluids into the mouth.

May 3. The stupor is more profound; the pulse has risen to 90; respiration continues at 20. A more active treatment was now thought advisable; four leeches were applied to the temples, and four behind the ears; sinapisms were placed on different parts of the lower extremities; the little patient does not recognise her parents.

4. Pulse 108; inspirations 16; incomplete paralysis of the limbs on the right side of the body. *Four leeches behind the left ear.*

5. Patient is in nearly the same state as yesterday; no answers can be obtained from her; excretions involuntary; pulse 90, intermittent; inspirations 24. *A blister to the neck.*

6. The patient is not so stupid as on the former days. The eyes are now open. She distinguishes objects, and answers by signs to the questions addressed to her. When asked to point out the seat of pain, she carries the left hand to the head. The right hand still continues incapable of moving. During the day the amelioration seems to progress very considerably. The child has recognised her parents; asks to drink, with a clear, articulate voice, and answers several questions addressed to her. The suppuration of the blister on the neck is kept up. Sinapisms are applied to the inferior extremities. The patient is allowed some milk and broth.

7. The intellectual faculties present the same phenomena as yesterday; but the incomplete paralysis of the limbs on the right side still persists. The pulse is now much more accelerated; the respiration has become embarrassed; deglutition is difficult; pulse 130; inspirations 40.

8. To day the pulse cannot be counted, from its great frequency. The patient still answers a few questions. She asked to drink once in the course of the day, and then gradually sunk until midnight, when a convulsive fit terminated life.

Body Examined Thirty Hours after Death.

Body emaciated; members relaxed.

Head.—The volume and parietes of the cranium do not present any thing remarkable. The dura mater is healthy. The great cavity of the arachnoid does not contain any serosity. Underneath the arachnoid lining the convex portion of the left hemisphere, we perceive a number of small round bodies of a tender yellow colour, hard as cartilage, and not larger than a millet-seed in most cases. Some, however, attain the size of the seeds with which birds are

commonly fed. These bodies, clustered together along the traject of the vessels, form small irregular plates or patches, which when examined by a magnifier, after having been detached, appear evidently formed by a reunion of small granulations. Upon separating the convolutions we find some of them adherent together on the convex surface of the left hemisphere, these adherences being produced by the pia mater, which is infiltrated with a yellow, consistent, steatomatous matter. On the right side of the surface of the brain, we find some granulations, a few patches of much less extent than on the left side. On the lateral surfaces of both hemispheres, the granulations are disseminated, but they again become confluent in the fissure of Sylvius. The pia mater does not contain the slightest trace of purulent infiltration: it is merely infiltrated, in the intervals of the granulations, with a little serosity. The membranes lining the base of the brain are intact. The ventricles do not contain any serum. However, the cerebral convolutions are flattened, and the cortical substance is often of a light chocolate colour; the medullary substance moderately injected. The brain is, generally speaking, a little less consistent than in the normal state; but does not present any marks of ramollissement at any point. We cannot discover any tubercle in the substance of the brain, which was completely divided by very thin slices. The pons varoli, the cerebellum, and its membranes, are intact.

Chest.—Both lungs are free from adhesions with the parietes of the thorax, but underneath the pleura which covers them, we perceive a multitude of small granulations analogous to those found underneath the serous membrane of the brain. In the parenchyma the tubercles are crude and much disseminated; the bronchial glands are also tubercular: the heart and its appendages healthy.

Abdomen.—Several convolutions of the intestinal canal adhere together by means of ancient false membranes studded with tubercles. We observe granulations underneath the serous envelope of the liver, spleen, and intestines in general. The stomach contains some residue of indigested aliment. On the anterior wall we observe the traces of two or three cicatrized ulcerations, round which the mucous membrane is pale and of good consistence. The interior of the rest of the intestinal canal does not present any thing remarkable.

Remarks.—This case presents several circumstances worthy of attention. Let us endeavour to seize the most remarkable. In the first place, let us notice the slow and gradual manner in which the inflammation of the brain was developed. This circum-

stance has been pointed out by several writers, particularly by ABRACOMBE, but it was impossible to explain the reason of the insidious manner in which the disease so often commences and goes on, before the fact was established by recent researches at the *Hopital des Enfants*, viz., that in a *great majority* of cases denominated "hydrocephalus," "acute meningitis," "meningo-encephalitis," &c., the inflammation of the brain, or its membranes, is either connected with, or dependent on, the formation of tubercular granulations in the cellular tissue of the organ.

This fact, to which we shall have occasion to refer more fully at a future period, is one of immense importance in the history of cerebral disease, and gives the key to various other phenomena which have hitherto remained obscure, or totally unexplained—for example, the hereditary tendency to hydrocephalus, its frequency in families subject to scrofula, its attacking successively many members of the same family, the great length of time during which the premonitory symptoms may last, &c. In the case now before us, the first symptoms of cerebral disease appeared two months before the acute attack; the patient, moreover, was evidently scrofulous; and here let us remark, that the duration of the premonitory signs, together with the history of the patient's life, previous maladies, &c., affords the best, perhaps the only means of distinguishing tubercular meningitis from the simple uncomplicated form. The transition from the chronic to the acute stage took place on the 29th of April, when the headache became suddenly augmented, and was followed by bilious vomiting on the 30th.

The connection of these two symptoms, acute headache and vomiting, without any apparent lesion of the digestive organs, is of the utmost value in the diagnosis of meningitis. We have not yet made an analysis of the cases we possess to determine this point, but we may affirm with confidence that they exist in five-sixths of the cases. Constipation is another symptom which frequently accompanies meningitis. In the present instance, the influence of the brain on the intestinal canal was sufficient to suspend the habitual diarrhoea under which the patient suffered, producing in its stead a degree of constipation sufficient to indicate the use of active purgatives.

But the symptom which we would lay the greatest stress on, is the state of the pulse at the time of the patient's admission. It was seventy-two on the third day of the disease, and (if we reason from the analogy of many other cases which we have observed) was not probably more accelerated during the two first days. This is a point upon which a grave error exists, even in the writings of the very best authors upon diseases of the brain; it is a doctrine received almost universally, that in the commencement of meningitis the pulse is feeble or accelerated; that the pulse *falls* as coma supervenes, and rises again shortly before death; indeed, we heard M. ANDRAL profess the same doctrine but a few hours before the present remarks were written. The present case is sufficient to demonstrate the contrary fact, and we possess ten or twelve other cases in proof, which we could bring forward were it necessary. In a great many cases of tubercular meningitis, the pulse is slower than natural at the very commencement of the disease; it preserves this slowness for one or two days, then mounts to eighty or ninety as coma supervenes, and gradually becomes accelerated, with the other symptoms of cerebral compression, until the patient's death, when it often reaches 140, 150, or 160. Instead of finding the pulse accelerated during the first two or three days of meningitis, we have frequently seen cases where the artery gave seventy, sixty, or only fifty, pulsations in the minute, and this at a period when the only symptoms of the disease were, headache, followed by vomiting, a very slight drowsiness, and irritability on touching the patient; with these symptoms we cannot admit the idea of effusion; besides, the slow pulse (as in the present instance) has been frequently observed where no effusion whatever existed in the ventricles. In many other cases, certainly, it does happen that the circulation is accelerated at first, then falls a little, and mounts again; but this may occur equally without effusion as with it, and, moreover, does not present itself so often as the case in which a slow pulse manifests itself long before the supervention of coma and insensibility.

The point of symptomatology we have now stated, is one to which we call the attention of those who have a disposition of studying extensively diseases of the brain.

We are persuaded that it is one of very great importance in the diagnosis of meningitis, and that in conjunction with severe headache, followed by sympathetic vomiting, it is sufficient to establish the existence of a malady which has hitherto remained obscure. Perhaps as much from the inaccurate manner in which it has been observed, as from the real difficulties that accompany its investigation. In fact, we are not acquainted with any other disease whose general symptoms simulate those of meningitis, in which his remarkable slowness of the pulse is to be observed.

A third circumstance worthy of notice, was the recovery of the intellectual faculties, and the power of speech, at an advanced period of the disease. This has been pointed out by several writers, who judiciously warn us against being deceived by this apparent amelioration. We have had an opportunity of witnessing this phenomenon more than once, not only in cases where the inflammation occupied simply the surface of the brain, but where the meningitis was accompanied by very considerable effusion into the ventricles.

Finally, we may notice the coincidence of tubercular deposits in all the other great cavities. This is an important fact in the history of tubercular meningitis. We have never observed (nor are we aware that any such case has yet been recorded) an example of tubercular meningitis, without, at the same time, finding a deposit of tubercular matter in the bronchial glands, the lungs, the mesenteric glands, or underneath the peritoneal lining of the contents of the abdomen. In two cases we have observed tubercles in the kidneys. This, we repeat, is a capital fact. The coincidence of hydrocephalus (in our view the same disease as meningitis, the presence of serosity having little or no influence on its march and symptoms in a scrofulous constitution) was long ago suspected, and even announced, by Drs. PARCIVAL and CRYNE, and several other of the best writers on this disease; but the fact was never demonstrated in a rigorous manner, until the researches made within the last three years at the *Hopital des Enfants Malades*, by Messrs. GRUBARD of Philadelphia, RUFF of Martinique, CONSTANT of Paris, and ourselves. Since that period we have observed a consecutive series of more than forty-five cases of acute menin-

gitis terminating in death. Nine-tenths of these presented a greater or less trace of tubercular affection of the meninges, and in all there was at the same time a deposit of tubercles in the cavities of the chest or abdomen.

P. H. GREEN.

TREATMENT OF FRACTURES WITHOUT SPLINTS.

TROUGH FOR THE LOWER LIMBS.

To the Editor of THE LANCET.

SIR,—I entertain no doubt that your readers have been strongly interested by the letters on the treatment of fracture, recently published in THE LANCET by Mr. Radley, of Newton Abbott. For one, I freely confess that the simplicity of his statements, and the highly practical character of his reasoning, have excited a very convincing influence upon my own mind; the more so, as I had in the following case, which I submit to you for publication, an opportunity of corroborating, so far as one case can do it, the principle maintained by Mr. Radley, viz. that in fractures of the long bones "splints may be dispensed with."

Case.—Mr. Richard Barker, a stout, elderly gentleman, while out with a coursing party near Cove, in Yorkshire, had the misfortune, in attempting to spring over a ditch (not on horseback) from the top of a stake-and-bound fence, to trip, in the act of precipitating himself forward, and fall, with the right leg bent under him. The tibia was broken across, about three inches below the patella, and what was quite as bad, the parts investing the knee-joint sustained such a violent wrench as to be followed by considerable inflammation and an ecchymosis, extending to the hip. He was fifteen miles from home, and extremely anxious to be nursed by his family, but the limb was carefully and skilfully reduced by Mr. Hill, surgeon of Cove, who, probably with a view to keep the limb steady during the journey in a post-chaise, had applied splints, firmly bandaged. I visited him at his own house on the same evening, about six hours after the accident, and found him suffering dreadfully. A mattress and bed having been laid on the floor of a small back-room, looking into his garden, he was conveyed there and stripped of his clothes, when I discovered that it was highly necessary, from the amount of heat and swelling, to undo all the bandages, for that night at least; twelve leeches were then applied to the knee, and a gin-and-water lotion was directed to be applied to the smoking-hot limb. These soon placed him in a state of com-

parative ease. The broken leg was merely laid in the hollow of a soft pillow, and the foot was kept erect by means of a heavy box, which afforded it a convenient prop.

In the meantime a strong iron rod, lengthened so as to allow it to reach across the room, was hung upon two hooks, at six or seven feet from the floor, so as directly to traverse the foot of the bed. A heavy piece of mill-board, eighteen by twenty-four inches, after being soaked in warm water, was then doubled upon itself, so that its sides approached each other within about ten inches, so as to form a trough, nearly a foot deep, into which was carefully spread a nice soft thin pillow, having a many-tailed bandage beneath. The sides of the trough kept the foot upright, and in preparing it I tore a piece out, to allow the ham to rest at ease; for the board, in a case like this, must be long enough to come quite up to each side of the knee, and project a few inches beyond the toes, and likewise be so deep as to completely receive the foot and rise above it. A piece of very strong tape, two yards long, was next passed under each end of the trough, and kept from slipping by holes bored through the upper corners of the mill-board. After the leg had been laid in this apparatus, the ends of the tape were tied together in one firm knot. A double cord, running through a swivel-ring that was made to slide along the iron rod, was let down and fastened to the knot, and the whole was thereby gently drawn up an inch or two, to clear the bedding, and was tied and made secure. To this he himself added what he called his "bridle," viz. a piece of cord fastened to the trough, and brought across the bed to his hand, so that after a few days he could steer the whole concern with great precision.

Mr. B. soon felt the convenience of this plan; he could turn in bed on either side without affecting the position of the leg and foot, and was enabled to ease nature with comfort and without assistance. After three or four days, by means of a bed-chair, he could sit up in bed to read and write, take his meals, and wile away the tedium of confinement. With the exception of a saturnine lotion, and loose linen rag placed upon the upper surface of the leg, nothing more was required, and the case got quite well in six weeks, and would have done so sooner, had not the inflammation of the knee-joint delayed us awhile. The union is so neat and perfect as almost to defy scrutiny.

The support afforded by the trough on every side, rendered the many-tailed bandage unnecessary, and it was laid aside almost from the first. My patient would now and then ventilate the limb by propping back the sides of the board with a bit of stick, and getting us to draw down the creases of his pillow-slip, so that a plan which will enable a patient to attend to these

small matters is no trifling improvement; for if the creases of the pillow will, in the course of time, not so torment a patient, what is to be said of splints and tight bandaging. The principle of treatment I consider to be the same as that of Mr. Radley, viz. the absence of undue pressure, the convenient access of ventilation, and other kindred means. The trough is, as I have described, by no means a substitute for a splint, but merely a convenient support, without pressure,—at all times the grand desideratum, and, in the case of fracture of the lower limb, an improvement even upon that gentleman's very scientific system of treatment. I remain, Sir, your obedient servant,

HENRY CHARLES SHERWIN,
Surgeon.

Hull, December 8th, 1835.

CASES OF BRONCHIAL IRRITATION

MISTAKEN FOR TRUE CROUP,

AFTER RUBEOLA;

WITH REMARKS ON THE

EXTERNAL APPLICATION OF CROTON OIL
IN CYNANCHE TRACHEALIS.

To the Editor of THE LANCET.

SIR,—I transmit the following remarks for insertion in your highly interesting and useful journal, and remain, Sir, yours, Ac.

JAMES INGLIS, M.D., M.R.C.S.E.

Castle Douglas, December 18th, 1835.

That epidemics are at their invasion more fatal, although less contagious, than at their height and decline, is a fact which long observation has confirmed. Russell on Plague, p. 261. The circumstances, however, are by no means universal, as was exemplified in this district during the recent stay of rubeola amongst us. It appeared, prowling about the country, in straggling cases, nearly five months ago. These became more numerous as the "epidemic constitution" advanced, till at length there was scarcely a family in which some members were not affected. It was not however until on the decline that the disease, which heretofore had been remarkable for its mildness, assumed an alarming aspect. Instead of running its course in its usual period it became more irregular, the rash not appearing until the fifth, sixth, or seventh day of the eruptive fever, and then appearing only perhaps on one cheek, remaining an hour or two, and again subsiding, or making its appearance, first on the lower extremities, and then on the face and upper extremities.

or perhaps on the same. Several years ago, when rubella was the principal organ which suffered, were the lungs. At that time the thoracic inflammation ran so high, that the abstraction of blood in large quantities was necessary, even in infants, and in many instances the regular pneumonic sputa were observed. The present epidemic is attended more by tracheal irritability than pulmonary, and the symptoms approximate those of croup. In only two cases, however, have I seen what might be called *regular croup*, and in them the "tussis clangosa" was well marked. In innumerable other instances there was an assimilation to it, and I believe that many such have been magnified, from mere bronchitic irritation, into formidable and successfully treated cases of croup. Of such is the following instance:—

Case 1.—H. C. a girl, *æt.* 8, was seized with measles, and treated accordingly. On the seventh day from the invasion, the eruption had faded, but the other symptoms became aggravated, the cough was more severe and urgent, the respiration difficult and sonorous, the pulse of considerable strength, and there was much pain of the trachea and upper part of the chest. A dozen leeches were applied, and, the bowels being torpid, calomel and jalap were administered. The leeching alleviated the respiratory symptoms, but severe abdominal pain, and tenderness on pressure over the umbilical region, quickly supervened. As the powder had not acted, an enema of oil was given her, which was soon returned, with very slight effect. Ten leeches were now applied to the abdomen, after which she experienced great relief, and had several copious stools. On the following day she continued to improve, until the evening changed the scene, when I was suddenly called, as the father expressed it, "to see the child die." On entering the room, I found her, indeed, apparently near death; the head, thrown back, was tossed from side to side; the countenance was anxious; the breathing so laborious as to threaten instant suffocation; and the pulse upwards of 160. I immediately bled her from the arm until an impression was made upon the pulse, and the symptoms having abated in some degree, a blister was put on the chest, extending up the trachea to the chin. Next morning she was much better; the blister had risen well, but, the bowels being slow, and having experienced the greatest benefit from croton oil, I applied two drops of it to the blistered surface, and this not only acted as a counter-irritant, but also had the desired effect upon the bowels. From this attack the child in a great measure recovered; but being of a scrofulous habit of body, and being much weakened through the loss of blood, *œdema* of the feet and legs appeared about ten days afterwards.

The anasarca speedily became universal, the respiration was greatly impeded, the resonance of the chest and the respiratory murmur became faint, whilst the sub-crepitous or mucous r le left no doubt but that the lungs, too, were *œdematous*. The child died in a semicomatose state, probably from effusion into the ventricles of the brain; but a post-mortem examination could not be obtained, from the prevailing vulgar prejudices against it.

In this case, some of the symptoms assimilated croup, but the cough though severe never had the pathognomonic sound, nor was the blood drawn in the slightest degree buffed. It was simply a local irritation.

The following case, whilst it is a contrast to the former, exhibits also the good effects of croton oil as a remedial agent in regular croup:—

Case 2.—I was called to see A. F., a child *ætat.* 3 years, three days after the subsidence of the rubeculous rash; her breathing was loud and sonorous; the inspiration difficult; the head thrown back; the eye suffused and watery; the arms thrown out from the body nearly at right angles, whilst sometimes the hand was suddenly raised to the throat, indicating the seat of suffering; the pulse was 180. These symptoms, together with the well-marked crowing cough, left no doubt as to the nature of the disease. Calomel and James's powder were immediately given, and a dozen leeches were applied to the upper part of the sternum and on each side of the trachea. Immediately after the wounds had ceased to bleed, an effective blister was applied, and more calomel and antimonial medicine was exhibited, by which two scanty greenish stools were passed during the night. Early next morning the dyspnoea and cough were nearly the same as on the preceding night. The blister had risen well; on the denuded surface I put two drops of croton oil. This acted freely on the bowels, and produced a marked irritation, which I did not regret, although it suppurred copiously; for, from the time of its application, the symptoms became less severe, and she made a rapid recovery. The croton oil seems to keep up its action on the bowels for several days after its application.

It is necessary to diagnose between these two kinds of irritation. In the one, depletion carried to a considerable extent is called for, even when the croton oil has been employed; in the other, more confidence is to be placed in, and less danger results from, local counter-irritation, as the detail of the next case will show.

Case 3.—M. C., four years of age (sister to the first-mentioned girl), was seized with measles; but the mother knowing the disease, as at that time raging, to be of a very mild nature, did not call medical advice

until the eruption had faded, and the tracheal irritation had fairly set in. The case resembled, as nearly as could be, that of her sister's, only the cough, if any thing, was more severe. As this was one of the first cases of that nature which had occurred, croup was dreaded, and she was in consequence freely depleted by leeches, and other antiphlogistic remedies were employed, by which the tracheal and thoracic symptoms were certainly overcome. But what was the result? When I called in the evening the little patient was fast slipping out of existence, in a low comatose state, with a small quick fluttering pulse. I immediately ordered her a strong beef-tea injection, which was retained about half an hour. This was ordered to be repeated every two hours. After the fourth she began to revive, the pulse got fuller and more moderate, and she was soon out of danger, but the complete recovery was slow. I am persuaded that had not these enemata been used, she would soon have been past all human aid, and *that* principally from the error committed in mistaking bronchial irritation for cynanche trachealis.

Before concluding, I may remark that children at the breast appear to be less liable to be affected by epidemics than those of stronger and maturer years. This, whatever may be its cause, appears to be a wise provision of nature; for neither could the infant bear with impunity a sharp attack of the disease, nor could the remedies requisite for its removal be employed with safety. The almost invariable answer of a mother, when asked regarding any one of her children which may have escaped some epidemic, when the rest of her family has been attacked,—that “it was suckling at the time,”—first led me to notice the fact; and I find that others also, on recalling to remembrance long-past experience, accord with the truth of the assertion. A brief case or two will suffice to show that there is at least some cause for this observation. The first is that of a woman, who, during the full blush of the eruption of measles, was delivered of a living full-grown child. She had a quick accouchment, and made a favourable recovery. It was her fourth child. Ere the measles had subsided the child was put to the breast, and continued to enjoy uninterrupted health, without even the slightest rubiculous spot.

The next case is that of a Mrs. R., who, having occasion to enter the house of a person labouring under typhus fever, caught the infection, went through the disease, and suckled her infant all the time, which remained unaffected; whilst a little sister, a husband, and a son, were all seized. And there is now a family under my charge, three of whom have been for the last three weeks affected with typhus, whilst the child in the cradle, in the same room, beside them,

remains uncontented. Other similar cases I might mention, but I have already trespassed sufficiently in occupying so great a portion of these valuable pages.

ANEURYSMS OF THE THORACIC AORTA.

To the Editor of THE LANCET.

SIR,—I was lately requested to make an examination after death, of the annexed interesting case, the particulars of which, with a few detailed circumstances, in reference to the patient's history, I offer for insertion in your valuable publication. I am, Sir, your obedient servant,

CHARLES J. H. RAY.

Tonbridge, December, 1835.

Jeffrey B., *etat.* 52, of a plethoric, unhealthy appearance, by trade a sawyer, and accustomed to hard labour, in the performance of which he had habituated himself to large drinkings, was, about twelve years since, suffering from a protracted pneumonic attack, that produced a troublesome cough, to which he was afterwards almost constantly subject. With this exception for the following ten years his health was tolerably good, or until he was accidentally struck by a heavy piece of timber on the upper part of his chest, which projected him forcibly against the axle of a waggon, near the centre of his back. At the time, he was informed that no fracture had resulted, but he was bled freely, and attended medically. From this occurrence to the period of his decease he always complained of much uneasiness in these situations, describing what he felt as a constant, dull, gnawing sensation, oftentimes distressingly aggravated. He had persevered in the use of the warm-bath, large doses of iodine, colchicum, and opium, the latter only appearing to be serviceable, by its composing influence. Cupping, also, and many varieties of counter-irritation, had been freely prescribed, but without benefit. From last September his sufferings increased considerably, and during his coughing, small portions of dark coagulated blood were frequently ejected. He was unable to exercise the left arm, to rest on the left side, or in a horizontal position, and could ascend the stairs only with great difficulty. On the 12th of November he felt much easier, and whilst exerting himself rather more than usual, coughed up a large quantity of blood, frothy in appearance, and of a bright red colour. This was followed by a state of coma, which continued for several hours. He was immediately bled, and stimulant means were administered, but death terminated his sufferings in rather less than

two days from the presence of this circumstance.

Autopsy, 20 hours after death.—The whole body presented, externally, a pale sallow aspect, and appeared slightly distorted on the left side. That side of the chest was evidently much distended, and afforded a solid resonance on percussion, whilst on the right side a perfectly natural sound was distinct. Immediately on dividing the cartilages of the ribs, on the left side, a large quantity of serous fluid escaped, and within this cavity was contained upwards of a gallon of blood, about one-third of which consisted of firm coagula. The superior lobe of the lung on that side had, from the pressure, collapsed towards its root, but the inferior lobe apparently occupied its usual extent of surface, although so much altered in structure and appearance that it almost entirely resembled the spleen; in its interior was formed a cavity that might have contained two fluid ounces; and the pleura, on its posterior surface, was closely adherent to the body of the descending aorta, near the situation of the sixth rib. From this vessel, between the sixth and eighth ribs, a large aneurysmal swelling had existed, which had also become connected to the inferior lobe of the lung; its gradual expansion from within outwards had completely absorbed at least two inches of the seventh, and about half an inch of the eighth ribs, commencing at about an inch from their articulations with the corresponding vertebra, and the fibrinous aneurysmal coagula were firmly embedded in this remarkable depression. The heart was of ordinary size and appearance, unusually flabby, and perfectly evacuated. The right lung was healthy. The whole body of the arteria innominata formed another vast aneurysm, which appeared to commence just before the origin of that vessel from the aortic arch; while its extent terminated at the bifurcation, nearly opposite the sterno-clavicular articulation of the right side. Its size was that of a large orange, and on its anterior aspect the parietes were ulcerated, and irregularly detached, to the extent capable of admitting a small egg. This large fissure was in immediate contact with the sternum, and from a mutual pressure had caused a considerable absorption of its substance, centred by two deep and distinct depressions, either of which was capable of admitting a sixpence, and near to the sterno-costal articulations of the first and second ribs on the left side. On attempting to raise the sternum, after a division of the cartilages, it was broken transversely in this situation, and exposed a curious state of the surrounding bony structure. The abdominal viscera were generally healthy.

INJECTION OF THE NITRATE OF SILVER

IN

GONORRHOEA AND LEUCORRHOEA.

To the Editor of THE LANCET.

SIR,—Having been the humble means of introducing to the notice of the profession the nitrate of silver as a local remedy in leucorrhœa and gonorrhœa in the female, and being interested in ascertaining whether the experience of others was likely to confirm the opinion I had entertained of it, I felt great satisfaction in observing so favourable a report as that contained in your journal of last week from the *North-London Hospital*. Dr. Elliotson, in his clinical lecture on a case of gonorrhœa in a female, when speaking of astringents and specifics given internally, remarks, "There is, however, a local application which is, I believe, recommended by many practitioners,* and which has, I think, by far greater power over gonorrhœa and leucorrhœa than any other local application, where there is no inflammation, and that is the nitrate of silver."

I shall make no comment on the above passage, except to observe that it affords me much pleasure to find the remedy favourably spoken of by so distinguished a member of our profession as Dr. Elliotson. My principal motive in addressing you, is to remark on the exceedingly weak solution which Dr. E. says he begins with, namely a quarter of a grain to the ounce of water. I need scarcely observe that I have used the nitrate of silver in those diseases of females in a variety of forms, and I have never found a solution of three or four grains to the ounce to create any painful sensations which have induced me to discontinue its use, or even to diminish its strength, unless, indeed, there existed excoriations, or a highly inflamed state of the parts; and as an instance of the extent to which its strength may be increased, I may notice the fact of a patient now under my care who has used it for a period of three years, in the proportions of seventeen grains to the ounce of water; this being the only remedy which has kept leucorrhœal discharge in check, and which I have no doubt has arrested the progress of organic change.

Permit me to suggest the necessity of avoiding the common pewter syringe, as, when used, a decomposition in the solution takes place. The short straight syringe I consider quite a useless instrument. The ivory or bone syringe,—my invention some time ago,—and which may be purchased at

* In a clinical lecture, published in THE LANCET of Aug. 11, 1832, Dr. Elliotson ascribed the proposal to employ this astringent in vaginal discharges, to Dr. Jewell.—ED. L.

most of the surgeons' instrument-makers (in the sale of which I have no interest, direct or indirect), will, I think, be found, from the material and shape, a convenient and efficient instrument, and may be used for injections of any kind. I have the honour to be, Sir, your obedient servant,

GEO. JEWELL.

Sackville-street, Dec. 22, 1835.

OBSTRUCTION OF THE NOSTRIL.

To the Editor of THE LANCET.

SIR,—I shall feel obliged if you will insert the following letter, and the remarks which I have subjoined to it, in your journal. The letter is addressed to me as the history of his case, by a patient. I am, Sir, your obedient servant,

S. PLUMBE.

Southampton-street, Dec. 14, 1835.

"Dear Sir,—As it appears that my case may possibly be instructive, I beg to hand you its history up to the time at which I consulted you. Previous to the attack which it describes, I had served during twenty-four years in India, and had never experienced severe illness of any kind.

"Shortly after a trip to Brighton, in August, 1834, I experienced a sensation of cold in my nose, with a catarrhal discharge, which soon afterwards became thick and offensive, causing me much annoyance. In December it became much aggravated, and in the subsequent May a partial obstruction of the right nostril took place, and increased daily. Shortly afterwards the left nostril became similarly affected for a short time, though only at intervals. The right nostril now speedily became quite impervious, and I found myself unable to draw air through it, or to expel air from the lungs by that passage. I experienced also great pain over the root of the nose, in the direction of the frontal sinuses.

"At about the latter end of May I consulted a surgeon at Brighton, and afterwards sought advice elsewhere, without any favourable result. I was recommended by one to use an injection of nitrate of silver, and by another to try one of tincture of kino, and a variety of other similar applications, all of which I patiently tried without effect. Other surgeons assured me that the constant sanious discharge from the nostrils, which excoriated my upper lip, and which had rendered me uncomfortable in society to an extent which I am hardly able to describe—might be got rid of by treating it as a gleet affecting the mucous membrane of the nose. Accordingly I used balsam of

copaiba and cubeba both locally and internally. Subsequently I was directed to use the golden filament, and to thrust it up the nostril by means of a camel-hair pencil; and, as a last resource, to give a trial to the injection of chloride of soda; and, finally, with the hope that the disease really existed in the antrum, I had made up my mind to the extraction of a molar tooth. Sea-side leisure and pursuits did me no good, either as regarded my general health or the local affection. I am, your obedient servant,

C. S.

"To S. Plumbe, Esq."

Remarks.—The case of this gentleman is, so far as my experience goes, one which the profession will consider rather singular and instructive, for although suffering for so long a period, the sequel is, that by the most simple means he has been restored to a state of perfect health, in the course of a few days. On examining the nasal passages, I found the right perfectly closed by the contact of the Schneiderian membrane at the point of union of the vomer with the cartilage and the ala, with the osse nasi, a fissure presenting itself there, instead of the open nostril. A probe was introduced on the first day, with some pain. On the second day a small pledget of lint was passed through an eyed probe, and introduced, with a little pain, and some blood was discharged. The quantity of lint was increased from day to day, and, finally, the probe reached the throat, and gave the opportunity of applying the black lotion to a part of the ulcerated surface. The day after, the probe passed into the throat, and, to use the patient's expression, "hurt the root of his tongue." He could then pass a little air, by great exertion, through the nostril, and some minute flakes of curdy matter were blown out. The sanious discharge continued for two or three days, the nostril being still half obstructed, when the patient, by a forcible effort, expelled a large mass of curdy matter, which I take to be the inspissated pus,—the ulcerated surface having been pouring out a healthy secretion of matter, but the passage before and behind having been so closed as to prevent the egress of any but its most fluid parts. Whether this view of the case be correct or not, a very large lump of the substance described was blown out, with little effort, into the patient's handkerchief, and he recovered within a fortnight, by the application of the black lotion, with a camel-hair pencil. The right nostril is now even larger than the left, and the patient's health is better than it was since the first attack.—S. P.

SOUNDS AND MOTIONS OF THE HEART.

REMARKS ON THE REPORT OF THE DUBLIN COMMITTEE OF THE BRITISH ASSOCIATION.

To the Editor of THE LANCET.

SIR,—The committee, appointed by the *British Association for the Advancement of Science* to examine into the nature of the heart's movements, and the causes of its sounds, have, after a series of experiments, arrived at some conclusions which are confirmatory of views which I have long since advocated in the pages of *THE LANCET*, and at other conclusions which are at variance with those views, and which I have been induced to quote and comment upon, from a desire to arrive at truth on a subject, which, to use the words of the committee, "from its importance, whether in a practical point of view, or as an object of philosophical inquiry, is deserving of further investigation."

The following quotations are from the report of the committee, as contained in the *Dublin Journal* for September 1835.

"Section 3.—*Conclusion 5.*—If the interval between two successive beats be regarded as divided into four equal parts; two of these parts may be allotted to the duration of the ventricular systole."

A similar opinion was advanced by Laennec, and since by Dr. Hope, but it has met with unanswered objections in *THE LANCET* of January 12, 1833, which contains the detail of an experiment by which the time from the commencement of the first sound to that of the second sound was carefully measured, and found to be a fraction less than one-third of the time, instead of two-fourths, as maintained by the committee.

"*Conclusion 6.*—The ventricles, in their systoles, approach the front of the thorax; and, by their contact and pressure against it, produce the impulse or beat of the heart."

In the natural state of the parts the ventricles must always remain in contact with the parietes of the chest, and can neither recede from nor approach them. If the ventricles did recede from the parietes, they would cause a vacuum between their anterior surface and the parietes; and this is so much at variance with physics and common sense as to be unworthy of a moment's consideration. In their deductions, the different experimentalists on the heart's motions have not contemplated the effect of cutting away a portion of the parietes of the cavity containing the heart. They have drawn their conclusions from changing one of the terms of

their proposition, and without making any allowance for that change. They have altered the mechanical relations of those parts whose motions they were about to examine; except as regards duration and succession, we might as well examine into the manner of the progression of an animal, having previously broken one of its legs, and set down its awkward gait for its natural movement.

If the above-mentioned alteration in the mechanical relations of the heart, and of the parts which enclose it, were allowed for, the results of their experiments would, I think, agree entirely with my description of the heart's movements contained in *THE LANCET* of February 8, 1834.

"Section 4. *Conclusion 3.*—That the first sound is connected with the ventricular systole, and coincides with it in duration."

That the first sound is connected with the ventricular systole had been long established; but that it is of equal duration will not, I think, be generally admitted; particularly as that duration is stated by the committee to be two-fourths of the time of one beat, in which case the duration of the heart's first sounds would be twelve hours out of twenty-four.

"*Conclusion 4.*—That the cause of the first sound is one which begins and ends with the ventricular systole, and is in constant operation during that systole."

On what ground is it stated that the cause of the first sound is of equal duration with the sound itself? There is no necessity for this. The sound of a drum is of longer duration than the blow which caused it; a harp-string vibrates long after the finger has struck it; and though the shock of the sudden tension of the ventricular valves be instantaneous, yet the vibrations excited by the shock of sudden tension may continue.

"*Conclusion 7.*—That it is produced either by the rapid passage of the blood over the irregular internal surfaces of the ventricles, on its way towards the mouths of the arteries, or by the bruit musculaire of the ventricles, or by both these causes."

Passing over the inaccuracy of stating the bruit musculaire to be the cause of the first sound—i. e. one sound to be the cause of another, I have merely to observe that the muscular sound of a powerful muscle bears no comparison in loudness to the heart's first sound; and if the passage of the blood over the internal surface of the ventricles be the cause of the sound, why does not the entrance of the blood during the diastole of the ventricles cause a similar sound? For be it remembered that the Committee state the duration of the systole to be two-fourths of the time of one beat; and, consequently, two-fourths only remain for a fresh supply from the auricles. Then, in both cases, the velocity of the blood being nearly equal,

why attribute a sound to the exit of the blood over a comparatively smooth path, when its entrance over a comparatively rough path causes no sound. Both of the above explanations are at variance with analogy, and they are equally so with pathology, for the loudness of the sound is, *ceteris paribus*, in the inverse ratio of the quantity of muscle; and when a bruit is heard, consequent upon the passage of blood over the surface of the ventricles, or of their orifices, the sound is so different from the true first sound, that it has become a diagnostic mark of functional or organic derangement of the heart.

The experiments of the Committee afforded no results which at all invalidate the opinion that the heart's first sound is caused by the auriculo-ventricular valves, and the only argument they advance against that opinion is contained in the following conclusion:—

"5. That it does not depend on the closing of the auriculo-ventricular valves, at the commencement of the systole; because such movement of the valves takes place only at the commencement of the systole, and is of much shorter duration than the systole."

The conclusions of the Committee afford, throughout, evidence that they consider the first sound of the heart to be a continued and equal sound; otherwise there has been a great omission in their not having stated the instant of its greatest intensity.*

The nature of the first sound is, however, a matter for the ear to determine, and not for argument; but I think I shall be generally supported in the opinion that it is an abrupt sound, and not continued and equal, as described by the Committee. If it be a continued sound, how could Magendie have supposed it to be the result of a blow, or an impulse of the heart, against the parietes of the chest?

My answer to conclusion 4 applies equally to conclusion 5; and I have merely to add, that the first sound occurs at the instant in which the valves close,—that the closure of the valves inevitably causes sudden tension of the valves,—that the sudden tension inevitably causes vibration of the valves,—and, therefore, as all sounds consist of vibration, and as no sound can exist without vibration, nor (within certain limits) any vibration exist without sound; and as, in the healthy heart, there occurs no phenomenon which is calculated to produce so

abrupt and strong a vibration as the sudden tension of the valves. From these facts and reasons I am led to attribute the sound to the valves. I am, Sir, your obedient servant,

E. L. BRYAN.

London, Dec. 16th, 1835.

LONDON PHRENOLOGICAL SOCIETY.

SKULL OF DEAN SWIFT.

At the second meeting for the session of this Society, a paper on the skull of Dean Swift was read by Mr. J. I. Hawkins. This skull was examined at the late meeting of the *British Association* at Dublin, and became the subject of an article in the *Dublin Phrenological Journal*, and other periodicals. Mr. Hawkins, on the present occasion, examined some points of debate which had subsequently arisen respecting it, and endeavoured to show that the real character of Swift was in accordance with the phrenological developments of the skull. The character of Swift in domestic life, and as an author, seems by many persons to have been greatly misunderstood; and amongst other individuals who made the examination of the skull a subject of ridicule against phrenology, was Doctor Macleod, one of the lecturers of *St. George's Hospital*, who adopted the vulgar belief respecting Swift, and strove to show either that phrenology had no foundation in truth, or that the skull was not the skull of Swift. As Doctor Macleod professed to be a medical man, Mr. Hawkins "probably on that account" took up his remarks, and allowed other writers to be answered in the reply which he had to give to the comments of the editor of Messrs. Longman's periodical.

The question respecting the identity of the skull was indisputably settled by Mr. Hawkins. Swift, being a dean of St. Patrick's, was buried in that cathedral. A short time since, some alterations were made in the edifice, which caused the exposure of the coffin of Swift and Mrs. Johnson, his "Stella." The circumstance coming to be known to Dr. Houston, of the Dublin College (whom Dr. Macleod describes in his pamphlet as a "buzzing busy-body"; Dr. H., with "impertinent curiosity," as Doctor Macleod declares, helped to "ransack the coffin," in order to find "a stumbling block for himself and other fools." This "worthy," continued Doctor Macleod, then displayed his "deplorable ignorance and folly," on finding that the skull was a "null one," by suggesting that the "mental powers" of Swift arose from a "diseased activity." (Mr. Hawkins in his paper said "that he remembered no such suggestion falling from Dr. Houston.") At the private examination of the skull, or at the

* Had this been attended to, the Committee must, I think, have been led to admit the explanation of the first sound, as well as that of the second, as first given by Dr. Billing, and first published in *THE LANCET* of May 10, 1832, and since brought forward by M. Roussel and myself, without, however, possessing the slightest knowledge, on my part, of Dr. Billing's Essay, or I should have acknowledged that priority to which, on this point, I consider Dr. Billing entitled.

subsequent public examination," and he believed that it never was uttered.) Doctor Macleod then produced in his pocket a pamphlet to show that almost every faculty of Swift ought, according to the doctrines of phrenology, to have been developed in a directly opposite extent to that which the skull was stated to present.

In briefly analysing the paper of Mr. Hawkins, it will be right to show, first, the grounds for believing in the identity of the skull, which was permitted to be temporarily removed (together with that of Mrs. Johnson) by the present Dean of St. Patrick, the Rev. Henry Dawson, for the express purpose of examination, when, also, drawings and casts of them were taken.—"There is no reasonable doubt remaining," said Mr. Hawkins, "respecting the identity of the skull. Dr. Houston declared that he himself took it from the coffin of Dean Swift, in the presence of several gentlemen. He also took from the adjoining coffin, on the same conditions, viz. that it should be returned in a few days, the skull of 'Stella,' Swift's female favourite, which skull Dr. Houston also produced at the meeting, and a more beautiful and well-balanced skull I never beheld. It was the beau ideal of a perfect female skull, and admirably harmonized with the character of Mrs. Johnson, as given by Sir Walter Scott, and some other of Swift's biographers. In order to satisfy some sceptics as to identity, the skulls, after having been exhibited at the meeting, were taken by Dr. Houston and replaced on their respective veritres, and several of the party ascertained the perfect fitting of the respective bones. Among the gentlemen present were several medical men from various parts of the United Kingdom; and a distinguished member of this Society, to whom I am indebted for this information (having myself left Dublin early on the morning after the public meeting), copied the inscription from the coffin of the Dean. This gentleman further informed me, that when the coffin was about to be first opened, the present verger of the cathedral said to the company—'Now we shall know whether old Richard Brennan told the truth or not. Brennan was formerly Dean Swift's servant, and afterwards was verger of this cathedral, until he became a very old man, and he used to say that the skull of Dean Swift was sawed in two before the interment, in order to take out the brains, and that he (Richard Brennan) held the basin to receive the brains.' Accordingly, on opening the coffin, the skull of the Dean was found sawn in two, to the very great astonishment of the verger, who had his doubts of old Richard Brennan's veracity thus removed. On the day of the public meeting," continued Mr. Hawkins, "I compared the skull with a cast which was a duplicate of the cast which is in the possession of this Society, and which is said to

have been taken from the Dean after death, and I found, by accurate measurement, that the cast belonging to the Society must have been a cast of the skull exhibited at Dublin, after it had been sawn in two, and the integuments had been again drawn over the divided parts. The weight of the plaster had evidently pressed upon the upper piece of the skull, and forced it about an eighth of an inch posterior to the lower portion, leaving a sudden step at the middle of the forehead, or, rather, an inclined plane, formed by the integuments not bending to the sudden falling back of the calvarium. Some persons imagined that this was an enormous wrinkle in the integuments during life, but no phrenologist could be deceived as to the real cause of the irregularity."

Next as to the vulgar opinion respecting the character and qualities of Swift. His *amatory propensities* were supposed by Dr. Macleod to have been little or none, and he referred to the opinion expressed in Scott's biography of Swift, in proof of the supposition. "Scott (quothe the dub) says, his whole intercourse with Stella and Vanessa indicates the very reverse of an ardent or a licentious imagination, and proves his coolness to have been constitutionally inherent, both in mind and person." And, again, "The coarse images and descriptions with which Swift has dishonoured his pages, are of a nature directly opposite to the loose impurities by which the voluptuary feeds his imagination. The latter courts the seductive images of licentious pleasure; but Swift has indulged in pictures of a very different class, and dwelt on physical impurities, calculated to disgust and not to excite the fancy." The anti-phrenologist urged also, that Swift had very little, if any, love of approbation, and in evidence of his statement, he again quoted Scott in the following sentence:—"There were three peculiarities for which he was remarkable, viz., his originality, his total indifference to fame, and the distinguished excellence which marked him in all his undertakings. As a literary man (the proudest light in which he can be viewed, if we except his patriotism, and even of that he was not vain), the careless mode in which Swift suffered his works to get to the public, his refusing them the credit of his name, and his renouncing all connection with the profits of literature, indicate his disdain of the character of a professional author."

The *benevolence* of Swift, said Roderick, was very great, as the subjoined words of Scott testify:—"The Dean's real and discriminating charity aimed at a better reward than popular applause. Even in his latter years, when habits of economy had assumed the appearance of parsimony, they could not overcome his principle of benevolence;" and, again, "he was charitable and benevolent

to the extreme limits of a moderate revenue."

The *ideality* and *wit* of Swift were said by the anti-phrenologists to have been remarkably great, and his "Gulliver," his "Tale of a Tub," and his "Battle of the Books," were pointed to in evidence. His powers of *imitation* they declared to have been very small, Swift being, they said, the most original of all authors. His power of *language* they considered also was extremely limited, because he "seldom used any but his vernacular tongue," and employed words only as "a means to an end." His faculties of *comparison* and *causality* they regarded as remarkably great, on the ground that he was "the finest and most subtle reasoner" that ever entered the field of politics or controversy.

These opinions were placed in array by the anti-phrenologists against the following extract from the table of the developments found in the skull examined at Dublin:—

"Amativeness, large.
Philo-progenitiveness, large.
Love of Approbation, very large.
Benevolence, small.
Ideality, small.
Wit, small (skull thickened here).
Imitation, rather full.
Number, moderate.
Language, large (skull very thin).
Comparison, moderate.
Causality, moderate (skull thickened)."

In opposing the views of the anti-phrenologists Mr. Hawkins drew a character of Swift, which tended to show that his actual propensities and faculties were very different from those described by his opponents, and that they were, in reality, in very exact accordance both with the developments described in the above list, and with the following account of other organs measured at Dublin:—

<i>Individuality, very large.</i>	<i>Order, full.</i>
<i>Form, large.</i>	<i>Weight, full.</i>
<i>Size, large,</i>	<i>Eventuality, full.</i>
<i>Locality, large.</i>	<i>Time, moderate.</i>

"The average of all these," said Mr. Hawkins, "will evidently warrant the opinion that, at the lowest estimate, the term *rather large*, should be applied to the intellectual indication, the lower percepts being *very large*, and the reflectives *moderate*." This remark was made by Mr. Hawkins in contradiction of a statement which became current, that the intellectual developments in the skull were very small, as compared with those which might have been expected in the head of such a writer as Swift. Amongst the biographers of Swift referred to by Mr. Hawkins in his estimate of Swift's character, is "the learned Dr. Beddoes, who, in the ninth essay of his work, entitled 'Hygeia,' has ascribed the vertigo, with all its distressing consequences,

suffered by Swift in his latter days, to habits of early and profligate indulgence; and he has argued upon his conduct towards Stella and Vanessa, as indicating the inflamed imagination, and the exhausted frame, of a premature voluptuary, who still courted pleasures which he was unable to enjoy." The same conclusion Dr. Beddoes was disposed to derive from the tone of gross indelicacy, of which Swift's writings afford so many proofs. Mr. Hawkins also observes that in his biography of Swift, at page 343, Sir Walter Scott, speaking of the impure tone of conversation prevalent in Swift's time, says, "Although Swift's offences of this description certainly far exceeded those of contemporary authors, the peculiarities of his habits and state of mind are also to be received in extenuation of his grossness." Again,—"*his delicacy must have been only occasional and capricious, for his journal furnishes many instances in proof of how little that delicacy influenced his own correspondence with females.*"

Mr. Hawkins also quoted the following passage from Dr. Barrett's Essay on the Life of Swift, to show the gross animal propensities of the Dean:—

"Nothing is more observable in the true and undisputed productions of Swift, than the pains which he seems to take in taking together the most nauseous ideas, and dwelling upon the most indecate images. It is unnecessary for me to bring examples of this strange propensity of his nature; which is the more serviceable to us, because he is almost singular in this respect, and it forms the strong outline that distinguishes him from almost every other writer. In a pamphlet which came out in 1704, called 'Some Remarks on the Tale of a Tub,' he is similarly described."

With regard to the extent of Swift's *benevolence*, Mr. Hawkins observes that Mr. Jeffery, in a number of the *Edinburgh Review* for 1816, says of the Dean:—

"He was neither a very dignified nor a very amiable person. The truth is, we think, that he was extremely ambitious, arrogant, and selfish; of a morose, vindictive, and haughty temper; and though capable of a sort of patronizing generosity towards his dependants, and of some attachment towards those who had long known and flattered him, his general demeanour, both in public and private life, appears to have been far from exemplary. Destitute of temp and magnanimity, and, we will add, of principle in the former; and, in the latter, tenderness, fidelity, or compassion."

Respecting Swift's *love of approbation*, Mr. Hawkins said,—"*I was informed in Dublin as a notorious fact, that in a fit of benevolence, the Dean lent small sums of money to several poor men, with some intention that it might be paid at a certain time; but that shortly afterwards he died, and acquired*

iveness, he instigated legal proceedings against the whole of them, and thereby ruined many industrious men and their families." Scott also says that in Swift's latter days he was "moody, melancholy, and ill-humoured, and absolute on all occasions."

In reply to the allegation that Swift was a man of great self and imagination, and had little imitation, Mr. Hawkins quoted first, the remark of Dryden on receiving some poetical exercises from Swift,—"Cousin Swift, thou wilt never be a poet," which Swift never forgot, or pardoned; and, secondly, Mr. Hawkins referred to the following remarks by Scott:—

"He never attempted any species of composition, in which either the sublime or the pathetic was required of him. But in every department of poetry, where wit is necessary, he displayed, as the subject chanced to require, either the blasting lightning of satire, or the lambent and meteor-like coruscations of frolicsome humour. We look in vain, in his writings, for depth of feeling or tenderness of sentiment; although, had such existed in the poet's mind, the circumstances must have called them forth. The mythological fable which conveys the compliments paid to Vanessa, is as cold as that addressed to Arden or to Miss Floyd. It is, in short, a kind of poetry which affects neither sublimity nor pathos." Again,—*"Yet this grandeur is founded not on sublimity either of conception or expression, but upon the energy of both; and indicates rather ardour of temper than power of imagination. *Pacis in ignis non recusat.* The elevation of tone arises from the strong mood of passion, rather than from poetical fancy." And, to conclude the extracts on this head,—*"But Swift, without ever trespassing into figured or poetical expressions, or ever employing a word that can be called fine or pedantic, has a prodigious variety of good set phrases always at his command, and displays a sort of homely richness, like the plenty of an old English dinner, or the wardrobe of a wealthy burgess. This taste for the plain and substantial was fatal to his poetry, which subsists not on such elements; but was in the highest degree favourable to the effect of his humour, very much of which depends on the imposing gravity with which it is delivered, and on the various turns and heightenings it may receive from a rapidly-shifting and always appropriate expression."**

Respecting the opinion that Swift ought to have had, from his faculties, the organ of language very small, Mr. Hawkins quotes from Mr. Walter Scott the following passages:—"The government of Ireland rewarded his eloquence as much as his learning." Again,—*"His powers of versification were admirably adapted to his favourite subject, satire, which is a handiwork to an inferior poet, as who is master of his*

art wears as a bracelet. Swift was of the latter description; his lines fall as easily into the best grammatical arrangement, and the most simple and forcible expression, as if he had been writing in prose."

Scott also observes that "logic, then deemed a principal object of learning, was in vain presented to the notice of Swift." This fact, said Mr. Hawkins, is in direct corroboration of the declared smallness of his organs of comparison and causality." In concluding his argument against the repeated declarations "that the character of Swift was the very opposite in every respect to the description given of his skull by the phrenologists, Mr. Hawkins said—"It may be remarked that Swift's very large individuality and form, large size and locality, full weight, eventuality, and order, will account for all his extraordinary powers of discrimination; and his very large secretiveness, destructiveness, and combativeness, combined with the above, would give that causticity to his satire, which made him such a pest to his friends."

We need not farther extend our extracts. We have suffered the subject to occupy so large a space in our Journal, chiefly because the skull of Swift has furnished, through misrepresentations and want of information, the most important occasion that has offered for many years to the enemies of the doctrines of Gall; and because, while the science of phrenology is one of great interest to medical men, too many of them have not time to examine the facts on which it is based, for themselves. We do not, ourselves, hold with many of the opinions that are entertained by its disciples, but we cordially concur with ANDRAL, in the general opinion expressed by him in a late address which he delivered as president of the *Phrenological Society of Paris*, at the annual meeting of the Society. A brief notice of the discourse appears in the *Edinburgh Phrenological Journal* for Dec. 1835:—"In this discourse," says the editor of the above-mentioned journal, "Andral endeavours to remove existing prejudices, by showing that Gall's leading ideas are in strict harmony with the principles which have always been followed by physiologists in endeavouring to discover the functions of the bodily organs, and that their truth is established by a body of evidence, direct and indirect, which it is impossible to resist. 'In what I have just said,' observed M. Andral, 'I have only one aim, and that is, to prove that the science of which Gall is the founder must henceforward be included among the *graves and serious studies of physiology.* The question is not now whether Gall or his successors have committed any mistakes in determining the functions of individual portions of the brain: even although none of the organs were yet ascertained, the fundamental principles of the science

' would not on that account have existed the less, and sooner or later they would have led to the accumulation of facts and the filling up of details. But if phrenology be true, do not concern yourselves about its future success, for there is no example of an important truth once fairly launched, having failed to make its way. It must, however, pay the usual tax of entry; some one must be put to inconvenience in its progress, and few people are fond of being set aside. *It has, moreover, the great fault of being younger than those whom it pretends to enlighten*; but let it alone, and it will soon throw all obstacles behind it with 'marvellous force.' We recommend these remarks to the serious consideration of such medical students as are deterred from the study by the influence of our own prejudiced professors. Andral's professional reputation and labours may be put in the scale against those of any of our living teachers."

The efforts of Doctor Roderick Macleod, and his coadjutors, to collect the "usual tax" from the new candidate for admission into the grave and serious field of physiology, form none of those "obstacles" which phrenology need use "marvellous force" to throw behind it.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Dec. 13, 1855.

MR. RICHARD QUAIN in the Chair.

ECZEMA.

Dr. Addison exhibited several wax casts this evening in order to illustrate the different forms of eczema. The Doctor congratulated the members on the fact that medical men were now paying that attention to the disease which it well merited and required, for the ordinary forms of the disease had hitherto been much neglected, indeed, he feared, treated with contempt; and the same with cutaneous diseases generally, although there was no class of diseases so little understood, and none more likely from a wrong diagnosis to affect the reputation of a medical man. He still maintained that the work of Wilson and Bateman contained the description of Mr. Thompson's case of eczema, with the exception of the exquisite form of exfoliation. As to vesication existing in the case, he had not the least doubt of it, as it oftentimes required the greatest attention to ascertain, and might escape notice therefore. He did not doubt, in fact, that it was frequently overlooked. Why the exfoliation had proved so exquisite, he presumed, was owing to the vesication not being fully developed, and occasioning an effusion of fluid between the cuticle and the

epithelium, causing a swelling, instead of the general moisture that is almost invariably found on the surface of the skin. Dr. Copland had, with his usual acumen, mentioned at the last meeting the presence of gastro-enterite with eczema, but he (Dr. Addison) believed that it was difficult to say which produced the other, as eczema often arose from local irritation, and was benefited by arsenic and other irritants, which would not, he thought, be the case, if eczema were dependent on gastro-enterite, which he did not, therefore, consider essential for its production. Eczema was often mistaken for erysipelas, but if the vesicles characteristic of the two diseases were observed, the error would be prevented; prothiasis was another form of cutaneous disease, for which it was frequent to mistake it, but reference to the history would always rectify that blunder.

Dr. JOHNSON thought that the novelty of the case narrated by Mr. Thompson, consisted in the periodicity of the disease. Had Dr. Addison met with, or Bateman noticed particularly, this phenomenon?

Dr. ADDISON replied that the statements of patients could not always be relied on, but he believed that about seven weeks was the usual period at which attacks returned, and in one case described by Bateman they returned every month for a considerable period.

Mr. THOMPSON said that had any student referred to Bateman's description of eczema rubrum, he would not have recognised the similarity between it and his Mr. T.'s case. It was far from his intention to deprive the merits of those authors. Since the last report the antiphlogistic treatment had been persevered in, and the patient had with benefit been bled twice; the blood was cupped. The subject here dropped.

Dr. JOHNSON informed the Society that it had to regret the loss of another member Mr. Mart, who had been carried off very suddenly by hemoptysis. He was seen for to see him, on Friday, at seven a.m., in consequence of the hemorrhage, but was unable to attend until five p.m. In the meantime Mr. Lambert was requested to see him and he bled him. The blood drawn was cupped, the first hemorrhage did not exceed a cupful, and throughout the day the sputa was only tinged. At his Dr. J.'s visit, the pulse was somewhat accelerated, the secretion becoming more florid, and the cough more troublesome. The friend said that the patient had had a slight cough for two months, with but little expectoration. He ordered a grain of lead with a grain of opium. The bowels were regular, but shortly after one dose was taken the bleeding returned, and proved fatal at nine p.m. Had any members seen or terminating with equal results?

Dr. ADDISON, finding that no post-mortem examination had been seen institute

waived giving an opinion, but remarked that cases of supposed aneurysms were sometimes found to have really been aneurysmal.

Mr. THOMPSON detailed a case which terminated as rapidly, the autopsy displaying an immense vomica, satisfactorily accounting for the result. A similar cause might be developed in the present case.

Mr. HORNE considered it but right to inform the members, in case an opportunity of ascertaining the truth should not be granted, that when he was requested to see Mr. Mart a short time back, it required not much difficulty to discover that his end was fast approaching, and of this he (Mr. H.) informed his friends accordingly; Dr. Clarke, also, under whose care he was from the beginning, had given no hopes of him.

Mr. LAMBERT declared with warmth that Dr. Clarke had not given any such opinion, but quite the contrary, and he (Mr. L.) also believed that his lungs were not affected.

Mr. HORNE intimated that there were gentlemen present who had heard the diagnosis of Dr. Clarke expressed, and Mr. DAVIDSON said that Dr. C. certainly had considered his case irremedial.

MEDICAL MAGNETISM.

After some further remarks from Mr. Verrall, and Drs. Stewart, Webster, and Blondell, Dr. Horne requested Mr. Thompson to report the progress of medical magnetism since the last discussion on the subject.

Dr. SCHMIDT first satisfactorily explained to the Society how Dr. Faraday's name had been used, although not by Dr. S. himself, and also alluded to the statement made by Messrs. Watkins and Hill, who it appeared had now authorized Mr. Davidson to disown on their part all knowledge of the competition in magnets. Dr. Schmidt said (as we understood him) that Mr. Wilkinson of Pall Mall was delegated by Lord Scarsboro' to make the proposal before stated to those gentlemen, that it was accepted by them, and that their failure was attributed to the inferiority of the English steel.

Mr. HALE THOMPSON now stated with regard to the question whether the magnet could produce physiological effects on the human body, that he must answer "yes," although Dr. Ritchie had denied the possibility of that result. As to its remedial efficacy, the time, he believed, had not as yet been sufficient to allow an opinion to be formed at the Ophthalmic Institution. From eight cases of amaurosis presented to Dr. Schmidt, four were selected, but these were not considered without their faults; in all of them some was produced, and great improvement was effected. But this afternoon, through the liberality in lending his magnet, and the skillful manner in which he (Dr. S.) had explained his mode of op-

erating, he (Mr. T.) had certainly produced a more decided physiological effect, by magnetizing a boy, who was received into the *Westminster Hospital*, with concussion of the brain. The pupils were dilated, and on first applying the magnet for three minutes, contraction followed, and on again employing it for five minutes, the same phenomenon occurred, to the complete satisfaction of himself and Mr. Snowden, a gentleman who had acted as house-surgeon to several hospitals. He thought it right to state, that, unknown to Dr. Schmidt, he had been told by Mr. Weiss that he could not undertake to make magnets of equal power to those of Dr. S.

Mr. HOLT stated that his daughter, who had been deaf for many years, and who had been placed in the circle of the magnets five times, had derived considerable benefit from their employment.

Dr. WEBSTER remarked, that out of the four cases which he had witnessed at the Eye Institution, only one received benefit; that of a lady, who affirmed that she could see much better after each application, all other remedies having failed to afford her any relief. In the second case the man saw worse. The other two received no benefit.

The PRESIDENT, before adjourning the meeting, remarked, that it was no unusual thing for amaurotic patients to say that they saw better after any new application was made.

THE LANCET.

London, Saturday, December 26, 1835.

DEPUTIES from the medical schools have been visiting the CHANCELLOR of the EXCHEQUER during the past fortnight, relative to the establishment of the new University. We hope that the whole of these bodies are satisfied with respect to the liberality of the scheme.

Still the draft of the proposed CHARTER is not before the public. Nothing, however, shall induce us to believe that the members of a liberal Government will shrink from placing before the community that document which it is their intention to convert into a law, by obtaining for it the sign manual of the King. The institution of the *Metropolitan University* will constitute an important epoch in the annals of the literature and

science of England. It will also affect, in great measure, the immediate interests of a large body of individuals, the conductors of scholastic establishments in and near London. The conduct, therefore, of the whole business should be as open, candid, and straight-forward, as the object sought to be accomplished is prudent, enlightened, and national. We repeat, however, that there will be no protection against the perpetration of what is unjust, unless a draft of the intended charter be circulated for the inspection of the public.

WHAT species of folly or cruelty can be practised which would not find defenders? A correspondent, who has most unwittingly adopted the signature of "PHILO-HUMANITAS," maintains that the charges advanced by the profession against the Poor-Law Commissioners and the Boards of Guardians are not well founded, or justly advanced; and the writer attempts to establish the accuracy of his position, by referring to the willingness with which medical gentlemen have agreed to become parties to the contracts in the Unions, and by referring also to the powers which the Commissioners can by right exercise, in conformity with the conditions of the Poor-Law-Amendment Act. Suppose we concede all that our correspondent has advanced,*—suppose we allow that the Commissioners and Boards of Guardians possess a statute right to treat the members of the medical profession with disrespect, with harshness, nay, with cruelty,—suppose also that there are a set of mercenary adventurers, who, having no feeling for the character of the profession to which they unfortunately belong, are willing to sacrifice every other object to the promotion of their own sordid and base propensities,—suppose, we say, that all this

* It would be useless to insert the note of "PHILO-HUMANITAS," as he attempts to prove no more than what we have, for the sake of argument, just conceded to him,

is admitted, does the connexion between the Poor-Law Commissioners, the Guardians, and the public, assume no other aspect? Does it present no wider view? Why "PHILO-HUMANITAS," and other writers of his intellectual stamp and caliber, in the blindness and the zeal, or in the muddy-mindedness of their folly, appear to forget the sole—the only object for which the poor-laws were instituted, so far back as the days of ELIZABETH—that of affording succour to the necessitous sick poor. This is an item in the account, which some of our hot-headed, over-zealous disputants will do well to include. The appearance of such a statement may be displeasing to the calculating political economists, and to the more philosophical, but still less generous utilitarians; nevertheless, it is quite certain that the mass of the English community, and, it is to be hoped, a majority in both Houses of the Legislature, will never forget that poor-laws were instituted for the protection of the poor, and that to such protection the poor are as much entitled as is the first lord in the kingdom to his landed estate. On a subject in which the feelings of humanity so strongly and convincingly admonish the mind that all attempts at mystification must fail in accomplishing their object, assuredly the people of this country—of course we refer to the *rate-paying* people—have not become so brutalized as to merge every question of human suffering occurring amongst the poorer classes of society, into a mere matter of pounds, shillings, and pence—in short, of setting up a saving of five shillings on the one hand, in comparison with relieving an afflicted fellow-creature from five days, five weeks, or five months, of bodily torture on the other!

Admitting, then, that the Commissioners and Boards of Guardians may, *by law*, exercise the right of giving to a medical practitioner the smallest coin in the realm, the treatment of the sick poor, at the rate of twenty or thirty pence per week, content that the moral obligation which that law

imposes, is altogether cruelly neglected, and is perverted into a base and unworthy object, which the provisions of no parliamentary statute ever can, or ever did, recognise.

When, therefore, a medical practitioner is insultingly offered a sum of money which is, confessedly, notoriously, an inadequate compensation for the labour which he undertakes, the executive authorities of the Poor-Law Amendment Act thereby virtually disregard the necessities and agonies of the afflicted poor, and they convert an Act of Parliament into a piece of insolent mockery. If the contract system, screwed down to the very last turn, be so exceedingly efficacious in the case of medical practitioners, why would not the same system be equally efficacious in fixing the salaries of the Commissioners and their worthy assistants? This branch of the subject must be mentioned in Parliament. It is really a pity that the Commissioners should be shut out from benefits which they so liberally bestow on other individuals. Why should *they* be encumbered with two or three thousand a year, when other persons might be found, equally competent to discharge their duties, for five hundred pounds per annum? If the contract system is to be pursued, let it be carried out to all functionaries throughout every department of duty in the new unions.

In making contracts with medical practitioners, every person, who is not utterly callous-hearted, will at once admit that the most scrupulous attention should be given to the means which the surgeon may possess of fulfilling the engagement which is enjoined upon him by the moral, as well as the written, obligation of the law. If the Poor-Law Commissioners could but behold in many, as in most, country parishes, the destitute, poverty-stricken, wretched hovels inhabited by the claimants on parochial relief, they would deserve universal execration. They would withhold from the sufferers the only consolation they could receive,—if they

shut out from them their only source of hope and comfort in the hour of bodily affliction and mental agony. The Commissioners may state, perhaps, that they are uninformed on these subjects, and that they consider that their duty to the rate-payers, as well as to the poor, is best discharged by ratifying, in all cases, the lowest tender which is offered by any medical practitioner who has received from one of the public bodies a legal qualification for undertaking the duties of his profession. In such a consideration there is plausibility, but no humanity. On the contrary, as the Commissioners must know, it is not in the power of a surgeon to attend and do justice to many hundreds of poor persons located over a surface of many miles in extent, for a sum of money, amounting, in many cases, to not one shilling a head for the medicines and attendance awarded to each individual. A thrill of horror darts through the blood, when reflecting, only for a moment, on what must be the consequences, the fatal, direful results, of such a nefarious engagement. With a practitioner thus employed there can be no alms giving; *he* evidently is not in a condition to afford extra-official aid to the miserable objects of the law's solicitude. He must indeed himself stand in need of that very assistance which he is made the ostentatious puppet and instrument of giving to others, or he would not, he could not, allow himself to be a degraded tool in the hands of men who appear to be ever occupied in working out the double purpose of destroying the poor, and accumulating insults on the members of the medical profession. The Commissioners and the Boards of Guardians ought to know that the mere testimonial of professional qualification is not a sufficient voucher for the character of that surgeon who undertakes, by contract, to furnish every requisite medical assistance to the parochial poor. Knowledge and skill in such a case are not all that is required; there are principles of honour, moral attributes, of the existence of which the most undoubted and

positive testimony should be obtained before thousands of helpless creatures are placed at the disposal of his tender professional mercies. What evidence of moral character have the Commissioners and Boards of Guardians demanded and received from the medical adventurers with whom the contracts have been ratified in the Unions? The gentlemen of the office in Somerset House will be called upon to place copies of these certificates before the Legislature. The whole of this subject, indeed, we are resolved, shall be thoroughly and searchingly investigated. Instead of treating with practitioners of known and acknowledged respectability, resident amongst the poor,—moving in their vicinage upon terms of benevolent and familiar intercourse with the sufferers,—strangers have been chosen, whose only claims to notice have been,—first, that they carried in their pockets a piece of worthless parchment, called a “diploma,” or “license;” and, secondly, that they would undertake, at less than a hangman’s wages, to reduce, at a rapid rate, the number of applicants for medicines and parochial relief. The Commissioners know, and so do the Boards of Guardians, that they would not treat the horses in their stables, or the dogs in their kennels, in this manner. Not a man of them would send to a veterinary surgeon, or a “dog doctor,” unless experience had given some assurance that the skill of the party would be exercised with honesty of purpose, and with kindness of feeling. A rule, therefore, is adopted by the Commissioners and Boards of Guardians, in the treatment of the sick poor of England, which no man of common sense and benevolence would pursue in the treatment of brute animals. Can such a system be sustained? Impossible! It is too revolting to be tolerated. It is repugnant to the national character of Englishmen; and the Legislature, in its wisdom, will beat down,—crush for ever,—that authority which has been so grossly outraged by the Commissioners, by their insolent assistants,

and by their too-complaisant Boards of Guardians.

When it is recollected that the medical contractors in the Unions are called upon to exercise their curative functions upon not only the most distressed, and most impoverished, but also the least informed, portion of the English community, too much stress cannot be laid upon the dependence which, in such cases, is necessarily reposed upon the humane integrity of the practitioner. In all instances of sickness, the surgeon, the physician, or the apothecary, can, if he be so disposed, conduct himself in a manner which shall deceive his unlearned patient; but in treating the inmates of our parochial work-houses and hovels, the sufferers are absolutely placed at the mercy of their medical attendant,—the *mercy* of a “contractor,” who undertakes the medical treatment of the poor, resident ten miles from his dispensary, at a charge of from one to three shillings for each person—a sum not amounting to the cost of a single set of shoes for the bare-ribbed, half-starved hack which takes him to mock the groans of the sufferer. Have the Commissioners ever paused for the purpose of asking themselves this question,—If medical practitioners are adequately paid in such contracts, what ought to be said of their charges while treating the sick in the houses of respectable private individuals?

If, then, it be confessed that the payment, in the case of the poor, is *not* an adequate remuneration for the duties which the medical attendant is, by law and moral feeling, required to execute, with what show of justice can the Commissioners and their tools insist that the terms shall not be enhanced,—in a word, that a just compensation shall not be awarded? *A priori*, we should say that the practitioner who agrees to undertake the medical duties of an extensive union at an income varying from £50 to 100*l.* a year (including all his medicines), furnishes by the fact of his accepting the very proposal which he makes, the most

Indubitable fact, that he ought to be spurned from the presence of the Commissioners. Such a man, indeed, not only offers to obtain money under false pretences, but at the expense of the welfare, nay the lives, of the most afflicted portion of his fellow-creatures. Such a man must carry the stamp of cruelty upon his brow. There can be no mistaking the characteristic features of such a being. He knows that in cases of fever, of inflammation, of visceral disease, he may neglect his patient with complete impunity; with complete impunity we say, because the mercenary brute is insensible to the throes of conscience. In the eyes of the relatives of the victim he stands exonerated from censure, even from accusation, because they are incapable of forming a notion of his guilt. *They* know not how often the visits should be made,—*they* know not the medicines which should be administered; the practitioner beguiles them with a soft assurance, with a smile of affability, but both emanate from the sanguinary spirit of a vampire.

Nothing can be more narrow-minded or unjust, than to regard the subject of medical contracts in the unions, as being exclusively a medical question. It may suit the purposes of factious and designing writers to restrict the limits of the inquiry within that narrow compass, but we can tell them that it shall be viewed upon a basis not less capacious than are the boundaries of England and Wales. It is strictly a *national* question, involving many of the noblest principles of humanity. As such, we shall again and again discuss the subject in the pages of this journal, and as such we firmly believe that it will be fully considered by a benevolent executive Government, and an enlightened Legislature.

Model in Wax, coloured, of the Otic Ganglion and its Neighbouring Parts. Published by Schlosser, 1835.

A most completely beautiful representation of an extremely interesting part of human anatomy, the modeller has submitted to our

view all but a portion of nature itself. The imitation is so close, so signally striking and true, that the mind is unavoidably turned from contemplating the obvious purpose of the design, to dwell on the marvellous skill of the artist. So nearly animate is the model, that we might almost suppose it to be traced by the hand of Prometheus. Criticism on the production must consist wholly of praise. A more perfect work of art of this description was never submitted to the inspection of the profession.

THE LATE DR. TURNER.

[From an Edinburgh Correspondent.]

ALL the members of the profession here deeply lament the premature death of Professor TURNER; for although he was not one of those brilliant stars whose rays have materially contributed to illuminate the dark paths of medical science, and his fame as a lecturer did not add much to the renown of the University, yet he was a man of considerable intellectual acquirements, a sound and judicious surgeon, and an assiduous and zealous teacher.

Dr. TURNER was educated chiefly in Edinburgh, where he served an apprenticeship to Dr. JOHN THOMSON, and was a contemporary of Dr. GORDON, our eminent anatomist. He commenced practice in one of the East-India Company's ships, and was afterwards elected a Fellow of our College of Surgeons, where he became intimately associated with his old preceptor Dr. THOMSON, who was at that time professor of surgery to the College. On the resignation of THOMSON, Mr. TURNER was appointed to the vacant chair. Some time afterwards, when Dr. THOMSON succeeded in accomplishing the favourite object of his life, that object to which the whole energies of his intriguing spirit had been directed,—the manufacture for himself of a chair in the University, he contrived also to create a chair of surgery for his *élève* TURNER. However much Dr. THOMSON was to be reprobated for the manufacture of those chairs, and the mode in which they were obtained from the Government, no one had any personal objection to offer to TURNER's appointment to one of them, though the object of the creation was palpable enough. The two self-elected professors, backed by their political ally at Holland House, succeeded in making their chairs sources of considerable emolument, at the expense of the unfortunate students in the University, for they contrived to get both the topics on which they lectured, added to the curriculum of "learning" which the pupils were compelled to attend in the Edinburgh School.

Dr. TURNER died, after only a few days' illness, at the 46th year of his age, and scarcely had he taken his lamented departure, that bourne whence no traveller returns, before a successor to the surgical chair of the University became an universal theme of conversation in the medical world of this northern division of the empire. Hardly, however, had the subject been broached, when, to the dismay of some, and the astonishment of others, Mr. LIXTON arrived from London. It is now, however, generally understood here, that the appointment of Sir CHARLES BELL is the alternative which will be consummated; but I am confident that I speak the sentiments of many, when I say that we want none of your London *pures* amongst us. You might as well send us a specimen from Rhubarb Hall, or a dowager from Pall-Mall East, equal, in poetical and in medical talents, to the distinguished individual whom your amiable President inflicted on the University of Glasgow. We are only astonished that a *pure* from one of your great hospitals should think of occupying so unprofitable a situation in Auld Reekie. There are several other individuals canvassing for the chair, and some of them of pretty good pretensions.

December 11th.

INTERCEPTED LETTERS.

"DEAR SIR HENRY,—It is singular enough that a few hours before your letter arrived, I had received the inclosed note, addressed to you from Madame V. You will perceive that she is *very* desirous to have the benefit of your able assistance. I am informed that she has an impression that the 'subordinates' under whose care she now is, do not understand her constitution so well as you do.

"MURRAY consents to publish your oration. It will not occupy more than thirteen pages of long primer type, well spaced, so that he fears that *one* shilling will be more than it's worth. I told him, however, that you did not publish for profit, and that you would distribute many copies gratis—but that he need not throw off more than 150, or 200 at most, for the *first* edition.

"I have had much to do with PARIS. He is one of those old birds that is not to be caught with chaff. I shall, nevertheless, keep rallying him, and driving at him. In the meantime, something under the name of 'Lectures' on *Materia Medica* must proceed in the Strand. We must get some one to act as *pro-tempore* lecturer. I imagine that none of the Fellows will undertake the unprofitable task; but, doubtless, some one or other of the Licentiates, on being asked by a Fellow, would not object to the labour,

though the title must be worn by PARIS, who, I am happy to assure you, will have no objection, for the sake of the College, to be called *professor* at least during the winter. He has made a kind of promise to lecture in January, but you know what *promises* are. He is evidently flattered by your opinion of him, to which I myself added that you thought there was something very imposing in his personal appearance, and that in a *given* he would make a most interesting and impressive lecturer. I have also assured him that he will have numerous invitations to dine with the Archbishop. This pleases him, for no man enjoys a gastronomic fete more than our friend PARIS.

"Nothing is talked of in the scientific world but the new Metropolitan University, and none of us can find out a man amongst our Tory friends, who can approach the Government without a suspicion being created, that would injure rather than help our sacred cause. There are only two individuals whom we can think of employing to discover the secrets. I allude to HOLLAND and BRODIE. They are both, as you know, every body's men. HOLLAND'S habits would enable him to find out something, and BRODIE, who loves to work under-ground, might contribute his aid. I know your dislike to any thing like intrigue, but we *must* employ men of that kind when circumstances demand. The secrecy which is preserved respecting the details, affords us reason to fear that your apprehensions are too well founded, and that all our exertions will not avail to preserve from destruction the rights and privileges of our venerable institution.

"In the meanwhile, however, as a certain quantity of time must be required to carry the diabolical project into operation, we must strive to raise what monies we can for the support of the College. I have kept the Fellows in total darkness about our finances, and none of them know that the building is deeply mortgaged, and our income so diminished. Let us make an effort to get a few more applicants before the licensing system is crushed *by law*. There are several men who have been lately purchasing degrees abroad, who I think would jump at a proposition from our College. The Scotch degree market being shut up, the subordinates have latterly sent to Frankenhansen, or some such place in Germany, for degrees. I will procure a list of these from the city, and, if you approve, will at once propose to sell them our licenses. We must let them understand that the examination will be very mild, simple, and god-like, — just such as CLENNING, who, by-the-by, has regularly come over to our cause, was blockhead enough to bring our Parliamentary Committee here to Oxford.

"As to our College *et cetera*, I have

“Taken the liberty to advise the Fellows that you will, in your usual liberal manner, forward to pay all the expenses of the tea, coffee, &c., and that they will take place the moment that political matters are so settled for the session that you know what ministers and dignitaries can safely be asked on the first night. I hope you will find leisure to compose a paper on the death of some more illustrious personages. To me it is unaccountable how great an interest all your papers create, and how much more people seem to wonder at the mode in which an illustrious man leaves this sublunary world than a man in the humble walks of life. We all look forward to your speech at our meeting on the 22nd, and we are full of anxiety to know more of the reasons why the Ministers have not consulted you in the new University scheme. I remain your dutiful and obliged servant, J. Mc. M.

“London, Dec. 1835.”

“DEAR SIR ASTLEY,—Will you join a deputation from *Guy's Hospital* to the CHANCELLOR of the EXCHEQUER to ask the right honorable gentleman how far the new University scheme will affect our school. Deputations are going from St. Bartholomew's, the Middlesex, the Bricks and Mortar in Webb-street, and several other recognised schools, and we shall be proud of your company from our own. Ever yours,

“B. HARRISON.

“Treasury, Guy's Hospital,
Southwark, Dec. 12th.”

MY DEAR SIR,—I think you will get on better without me; I am very busy in my museum; but Mr. BALDERSON shall go as my representative if you do not object. In truth, however, I think it is a useless mission, for I expect that the CHANCELLOR of the EXCHEQUER will only tell your Majesty, as he may most correctly and wisely, that you ought to know a d—d sight better than he, what a liberal plan will do for all the schools.—I know well enough what it will do for our College. In fact, I have long been convinced that in its present form and constitution it cannot last. I don't speak of its fate with regret. It has had its day, and I may tell you plainly, that I intend, in the present inevitable state of things, to give the Government all the support in my power, in arranging their new scheme. Ever yours, my dear Sir,

A. C.

● Conduit Street, Dec. 13th.”

MAC,—Poor WARREN is dead. I don't know your last why I have gone down ever since I visit him, when I must have well known in how little estimation he held

me. I am aware that WARREN never appreciated my talents as he ought, but that was no reason why he should not reap the benefit of them when he was ill. And, besides, it was just to me that the world should at least suppose him to hold a high opinion of me, for I mean to skim the cream of his practice—such of it at least as is left. I was rejoiced to see, in our last number, the Manchester weaver's notice of the Chapter on Mind, in ELLIOTSON'S Physiology, and I can tell you how to turn it to account for me, who have worked so hard for you. It has struck me that the Professor at the London University is not unlikely to step into WARREN'S shoes, for WARREN was also a liberal, you know, and to prevent this the opportunity occurs of getting up a cry of materialism against ELLIOTSON. It looks rather odd, to be sure, to see the Manchester critic seizing at this time of day upon opinions which have been in so many old editions of the Physiology; but never mind that. It will seem to the public all new, and the way to proceed is this:—Advertise the Manchester article every where in connection with ELLIOTSON'S name. Attract attention to it through the papers. Call it an “Elaborate and Convincing Refutation of the Doctrines of *Materialism* broached in Dr. ELLIOTSON'S Physiology,” or something of that kind—in CAPITALS, well displayed; I'll pay the cost. You know me too well to doubt that. Only do it well; frighten the old women—every body—and raise a proper feeling of indignation in the public mind. These are “no popery” times, and all liberals should go to the stake. In the mean while I shall set every other wheel in motion to forward my object. I have plenty of time to attend to the matter, having given up my appointment of Medical Examiner to the East-India Company, though, by the way, I have sat in the chair so long—ever since I commenced practice (thanks to my uncle, the Governor)—that I leave it not without a pang. By-the-by, some, I find, suppose that the Company will give the appointment to a physician who is practically acquainted with the diseases of tropical climates; but I don't consider that at all a necessary proviso. Indeed, the credit I have earned in performing the duties, proves the contrary, and I believe it will be given to HUME, as the Duke has made interest for him. I can send you no articles at present; but if you are dry in a fortnight, I'll help you with a page or two. In the mean time be assured, that whenever I am away, my patients shall be sent to you; but don't order any *mica panis*, or else write too obscurely for inquisitive patients. Yours at all times,

“F. W. C.

“Brook-street, Dec. 5.”

THE METROPOLITAN UNIVERSITY.

To the Editor of THE LANCET.

SIR,—As the enclosed letter to the Rt. Hon. T. S. Rice relates to a matter of great importance at the present time, I shall be obliged by its insertion in your pages. I am, Sir, yours, &c., JOHN EPPS, M.D.
89, Great Russell-street, Dec. 17, 1835.

To the Right Honorable THOMAS SPRING RICE, M.P., Chancellor of the Exchequer.

Sir,—When Vice clothes itself in the garb of Virtue, she is the more dangerous, because more difficult of detection; and hence, sometimes, even the good embrace her, without being aware, until the consequences of the embrace become apparent, of the hideous being they have acknowledged.

Thus attired is MONOPOLY.

To the hatefulness and the injuriousness of monopoly, the Government of which you were and are now a member, have testified by the measures introduced in various sessions, to destroy, or at least to mitigate, the evils of some of the most extensive monopolies. So that every unbiassed man, looking upon these proceedings of the Government, has come to the conclusion that the necessity is seen, on the part of the Ministry, of abolishing all monopolies, so far as such abolition can be effected with safety.

One monopoly that stands most in need of abolition is exhibited by the Universities of Oxford and Cambridge. These Universities exclude all save those who are of a particular creed, and thus make the honours of literature and science to depend, not upon a man's talent, but upon his religious opinions.

The atrocity of the monopoly thus created is now very generally felt, and a general cry for the abolition of the unsalutary power perpetuating this monopoly, has been raised through the kingdom.

To that cry it has not been possible, on account of the peculiar constitution of the Universities of Oxford and Cambridge, to pay any effectual regard.

What has happened? The evil is felt. Individuals, not content to wait till the removal of the evil shall be effected by the influence of public opinion, acting through the House of Commons, and through that House on the House of Lords, determined to realize the privilege of obtaining the power of conferring honorary degrees without the degrading condition of submitting to a particular creed.

These individuals, instead of going to the Legislature, and demanding that an University should be established in the Metropolis, combined together; and, by subscribing for certain shares, constituted a large proprietary of shareholders, who determined to

raise an edifice, ~~with~~ with the adjuncts of ~~the~~ ^{the} ~~University~~ should be called "The University of London."

The building was raised; the teachers were appointed, and the system of instruction was commenced. Forthwith an attempt was made by ~~them~~ to obtain a CHARTER, not merely of incorporation, but to secure to them the power of conferring degrees.

It seems, moreover, from the nature of the motion of Mr. Tooke, in the House of Commons, on March 26th, 1835, that a royal charter of incorporation had been drawn up and approved of by the law officers of the Crown in the year 1831.

Now, Sir, what would have been the consequence of giving such a charter* to the London University? What but the establishing another monopoly? a monopoly of teachers.

The proof is easy. The object of a college and of all schools is to teach. The skill of the teachers, and the means possessed for the manifestation of that skill, ought to be the only grounds upon which any pre-eminence can be claimed. Each teacher becomes interested in communicating scientific truths in the most clear and comprehensive manner. There is a beneficial, a scientific rivalry, pregnant with advantage. But if there be any exclusive advantages possessed by particular teachers, what is the consequence? To render this apparent, take two lecturers, A and B, both of whom are equally talented. They make known that they lecture. They are equal in talent to instruct, and in the possession of means for instruction. Those anxious to be instructed hear of their intentions, and determine to place themselves under their instructions, some under A and some under B. But, by some contrivance, B has managed to obtain a peculiar and exclusive advantage; namely, that his pupils will be enabled, by attending his lectures, or teachings, to obtain a degree, which the pupils of A will not. Does it not follow that *plus* advantage added to *equal* talent must give B an injurious superiority? And, in addition, does it not follow that this superiority must be injurious to A? And is not the possession of such a superiority a manifestation of the exclusive principle,—a monopoly of the worst character?

Such a monopoly would have been established, had the London University obtained the charter which they sought. But they would have obtained a monopoly of a more glaring character, had the charter sought for been granted.

The senate would have been the examining body. The professors, or the teachers, would have become the examiners of their own pupils.

* This charter included the power of conferring degrees.

It is true, Sir, that the plan now proposed by the Government obviates the latter evil. And in this view of this important matter every enlightened mind must agree with Mr. Hume, that "the Government is in the novel position of taking the lead of them" (the proprietors of the University) in the general liberality of the plan."

What then is proposed by the Government? It may be stated thus:—

1. That a board of examiners, to be termed the University of London, shall be authorized by charter to confer degrees.

2. That pupils from University and King's Colleges shall be admitted to examination.

3. And that any other bodies for education, whether incorporated or unincorporated, may, from time to time, be named by the Crown, and their pupils be admitted to examination for degrees.

Such are the intentions of Government; intentions indicative evidently of the fact, that degrees are to be conferred upon the prosecutors of every department of learning and of knowledge, divinity excepted.

To this no liberally-minded individual can object. But, in developing the intention, one circumstance occurs which mars the beauty of the plan. It is this, that while "the University" can confer all degrees save those in divinity, an excellent exception, the individuals on whom these degrees are to be conferred are not all who may be qualified by their learning and knowledge,—not all who have laboured hard to acquire every necessary information, but those only who have been educated at "any chartered college within the Metropolis."

Now, Sir, is not this giving a positive monopoly to the teachers in chartered colleges? Is not this as much as asserting that the education of students is better within the walls of a chartered college than within the walls of any other building? Is not this a spirit of intellectual consecration of bricks and mortar? Is not this a sacrifice to the god of wealth, because the largeness of the building seems to have some weight in the matter? Finally, Sir, is it not saying to those beginning their studies in London, "Gentlemen, go to the King's College and to the London University (to be called "London University College"; become pupils there, for there you will have talented lecturers: and there, in addition, you will be able to gain honorary degrees?"

But, Sir, it may be said, that the Government plan is not so exclusive as this; for it is expressly stated, in the communication from Downing-street to the Council of the London University, dated Aug. 19, 1835, that "Any other bodies for education, whether incorporated or unincorporated, may, from time to time, be named by the Crown, and their pupils be admitted to examination for degrees."

But, Sir, as is stated, in the preceding

clause, that a particular class of pupils is at once admissible to examination for degrees; and this particular class consists of pupils from University and King's Colleges.

Here, Sir, is given at once a priority to those educational bodies over other schools,—and why? Are they better teachers at these thus styled "Colleges" than at other schools? Personal comparisons would be invidious, and therefore should be avoided. But it may be asked without fear, Is the education at either of these institutions superior, in reference to the production of real medical qualification for medical practice, to that given at the "private" schools, as they are called?

Let, Sir, an application be made to the examining Boards of the Apothecaries' Company and of the College of Surgeons, and let a report be presented from each body, of the pupils passed or rejected, as belonging to individual schools; and I myself, as an individual private lecturer, am quite willing to abide by the result, as a testification of the nature and of the sufficiency of medical education, as given at the private schools.

Is it then just, Sir, that the pupils of any one institution, or of any institutions, should have the priority given them of starting in this intellectual race for intellectual honours, in advance of the pupils belonging to other institutions?

I sincerely believe, from various sources, that it is the wish of Government to act in this matter with the greatest fairness; but is it not apparent that the naming the pupils of the London University College and of King's College is giving an undue priority?

It may be asked, "What then do you propose?"—I propose, Sir, that the Government of this country, recognising the grand truths, that science has no country, that scientific men have generally been those who have received no aids of collegiate education, should declare, that

Literary and scientific honours shall be open to every individual, who can prove himself qualified to possess those honours:

And that, in addition,

Those honours being gained, the individuals gaining them shall have every legal privilege connected with the qualification.

With regard to the latter point, it would evidently be absurd to give an honorary degree as indicative of qualification, and then, afterwards, to require the qualified to pass another ordeal, previous to the realization of the benefits of such qualification.

It is true that such a plan would require the sweeping away, in the present state of society, of many scientific, or rather pseudo-scientific, nuisances; but the gain would be immense; the loss would be nothing.

And what a noble memento of the Government such a proceeding would be! What a pleasurable satisfaction would arise

in the mind of yourself, a member of such a Government, in contemplating the fruits of such a labour! And finally, what a thought to console at the close of an honourable life,—“I have been an instrument in removing a mighty barrier to the diffusion of education and enlightenment amongst the people.”

Trusting, Sir, that you are capable of appreciating the high behests connected with the decision of Government on this important question, I have the honour to remain, your obedient servant,

JOHN EPPS,

Lecturer on Materia Medica and Chemistry,
and Director of the Royal Jennerian and
London Vaccine Institutions.

METROPOLITAN UNIVERSITY DEGREES.

REPLY TO THE LETTER OF “A KING'S COLLEGE STUDENT.”

To the Editor of THE LANCET.

SIR,—I did not expect that the suggestions which I offered in THE LANCET of Dec. 5, respecting the conditions of granting degrees in the New Metropolitan University, would have met with the opposition which “A King's College Student” has offered them. I did not expect to be so hastily dignified with the title of “opponent,” by a gentleman who is already in possession of those advantages which I merely suggested should be extended to others. But, Sir, as he has appealed to the public to decide which of us is right, I am induced to reply to his remarks, and shall then leave the subject with perfect confidence in your hands, satisfied also in what manner the public will ultimately decide on the question. My opponent takes occasion to reprove me for calumniating a body of men who are “*not yet called into political existence.*” How can I have effected that impossibility? However, the commencement of my letter shows that I did not refer to any set of men, but to a proposed system, which I conceived to be objectionable. But I proceed to his objections.

Certificates of moral character, he says, are frequently forged. To this I reply, that a written character ought not to be accepted, unless some means are taken to ascertain that it is authentic.

He objects to allowing young men to graduate without having been College Students, because, though it might benefit a few, it would ruin the majority, for many who do now attend lectures occasionally, would not then, he says, attend lectures at all. And suppose students did not attend lectures at all? Suppose they did not study? Why then they would be certain of not obtaining a

degree. In fact, it is more than probable that instead of the new system causing ruin to any one, it would arouse students to a sense of the necessity of profound study, and induce them to seize every opportunity adding to their mental and professional attainments.

My opponent imagines that I think the students who neglect the lecture-room, more profitably employed elsewhere study. Those gentlemen who neglect the lecture-room do so, I should suppose, for far less noble pursuits than those of science. I quite admit the benefits of oral instruction. I merely argue that if a student does, without its aid, obtain as much knowledge as one who is in possession of its advantage he ought to be entitled by law to the same honours, and the same standing in society.

My opponent next says, that a man can not obtain sufficient knowledge from books alone, to qualify him to possess a diploma. I reply, that a Board of Examiners could fully test this. They can test his knowledge of anatomy and the operations of surgery on the dead body, his knowledge of the practice of medicine in the wards of an hospital, his knowledge of chemistry, if need be, in the laboratory.

He says, that the duration of the examination which would be necessary under the new system, would be so long as to render impracticable in operation. I reply that lengthy examination is not impracticable. As it is designed to secure the public against incompetency, the examiners would undoubtedly be fully remunerated for their time and there is no other point than that in question. My opponent himself says, that certificates are often forged (and I know they are often given without being deserved) how then can he support a system in which he would allow certificates to play any part in the conditions of granting diplomas?

His last, his most startling, and his only sincere ground of objection, is based on the supposition that the new system would tend to deprive the graduates, as a body, of the respectability. Why, truly, if respectability consists in the exclusion of all but the rich from literary or scientific honours, the new system most certainly would ensure respectability to the class of graduates; but in as I apprehend, respectability belongs to the mind and not to the pocket, then what is the worth of my opponent's objection? For although he may exult at this exclusive system, although he may feel indignant at the thought of a “farmer's or a tradesman's son” aspiring to the honours of learning and skill, yet I can tell him that farmers' and tradesmen's sons deem it as much their right to aspire to reach the eminences of science and will demand (if they should be prevented from learning from the corruption of the present system to despise them) equal honours with those, who, though rich, possess no great

Attainments. But the "Student of King's College" is liberal enough to say that he has no objection to the low-born being raised by their abilities to eminence in a few instances. And why so liberal as regards a few? Because he cannot help himself. Those few have raised themselves already. My opponent and the "exclusive" party, would grant no opportunities to low-born youths to raise themselves. But when, despite all obstacles, despite all prejudices, genius has broken through the castes of society, and raised itself by force of talent to its appropriate station, they then would "not object to a few poor students" occupying stations in the ranks of titled men of science. Whatever exclusions the rich in society may desire to enforce, nature has made no law which peculiarly fits the wealthy for the purposes of literature and science, but rather the contrary. Arrangements of society which set at defiance the laws of nature, are most iniquitous to God and man. In conclusion, let me express a hope that the "King's College Student" will now perceive that he has advocated some erroneous opinions. It is lamentable to hear a gentleman who professes to be a Student of Medicine, with a desire to obtain eminence in the science, supporting the cause of those giddy creatures whom he describes as forsaking the lecture-room for the excitement of dissipation, and doing so at the expense of ardent students who do not chance to be the sons of wealthy men. I am Sir, your very obedient servant,

A STUDENT.

London, December 15th.

METROPOLITAN UNIVERSITY DEGREES.

MONEY AND CERTIFICATE QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—In differing from the views of "A King's College Student" as expressed at page 420 of a late number of THE LANCET, permit me to make a few observations on the two great questions of subjecting candidates for medical degrees to a prescribed course of study, and leaving them to follow that which best suits their taste and convenience.

Your correspondent cordially agrees with the proposition, that an unequivocal certificate of good moral conduct should be required; yet according to his arguments for the present system as a means of sustaining the "respectability" of the profession, he would effect this object not by a written statement of morality, but by a plan which, while it affords the aspirant an opportunity to conceal his faults, also to hide, "a multitude of sins." A pocketful of money it is

clear not only opens to a giddy youth an enticing vortex of dissipation, but furnishes him with those "oblivious antidotes," the false certificates, by which he obtains admission to an examination, at a time when, probably, having exhausted his pecuniary resources, exigency compels him to stand the test. To the dread of this test, inadequate as it is, will such an one owe the little knowledge he may be found to possess, and not to any obligation imposed and inevitably exacted by the certificate system. How often does it happen that the candidate, after having squandered away his time, and deluded his friends by the display of certificates of "diligent" attendance on lectures, &c., has recourse to a "grinding," by which he is "crammed" in a few weeks with what is supposed to have taken him some years in acquiring!

Your correspondent's assumption that an expensive education is likely to be obtained only by persons of good birth, is erroneous indeed. Were the degrees given to a student to be measured by the length of his purse, the sons of "farmers" and "tradesmen" would carry much more respect than your correspondent seems to allow them. I recollect the landlady of a small country inn, who was bringing up her son as a "doctor," boasting that he would "come out as big a gentleman as any in the land," because, forsooth, she was plentifully supplying him with that which in her estimation could not fail to effect the object. This feeling, vulgar as it is, will have at least the appearance of truth on its side, so long as illiterate young men can find their way into the profession upon a money qualification.

As my object has simply been to show the fallacy of an hypothesis upon which is based many of the arguments in support of the certificate system (which, from observation, appears to me to work very ill), I here conclude. What alterations are most likely to answer, it is not for me to suggest. This is now, happily, the province of an enlightened body of individuals, to whose judgment, aided by THE LANCET, and the experienced voice of its Editor in the senate, the public may confidently commit the cause he has long so ably advocated. I remain, Sir, yours truly,

A LONDON UNIVERSITY STUDENT
OF MEDICINE AND SURGERY.

December 17th, 1835.

ST. GEORGE'S HOSPITAL.

DISEASE OF THE BONES OF THE ILIUM.

WILLIAM HARDEN was admitted, Sept. 16th, into Winchester ward, when, Sir BENJAMIN BRODIE being out of town, Mr. CUTLER took charge of the case, who at once told the patient that his was not a

fit case for the hospital, and then added that he must take rest and apply poultices, these remedies being of great efficacy in such cases. The case in which this treatment was to be adopted was one of diseased bone of the left ilium, of eight years' standing, with two large sinuses (one leading from the trochanter major, the other from the sacrum), extending to dead bone. Leeches were afterwards applied, and house-physic was given, and on the 25th of September, Sir BENJAMIN first saw the man. We then learnt that about eight years ago he first felt pain in the affected hip, for which a surgeon to whom he applied, also recommended rest, at the same time opening two large abscesses (which have now degenerated into sinuses) and letting out a large quantity of matter. The pain has continued more or less ever since. The hip-joint is nearly ankylosed, but the patient complains of no particular fixed pain in any part of the limb. The thigh of the same side is enlarged, but there is no perceptible difference in the length of the two limbs. He was ordered half a pint of the compound decoction of sarsaparilla, with two drachms of the extract of sarsaparilla daily, and one-eighth of the oxymuriate of mercury in a pill. This plan of treatment (according to Sir B. BRODIE's usual method) will be persevered in for some time, to produce an effect on the constitution.

Oct. 9. The patient has steadily persevered in the use of the remedies until this day, when the oxymuriate of mercury having deranged his bowels, it was discontinued *pro tempore*, and he was ordered the *Infusio of Casaria with Tincture of Kino*, twice or three times daily.

21. He has continued the medicines with much benefit. The diarrhoea is better, and there having been some sero-purulent discharge from one of the sinuses, Sir B. BRODIE laid open a fresh abscess at the upper and outer part of the thigh, from which blood, pus, and putrid coagulum, were discharged. A poultice was ordered to be applied, and the sarsaparilla medicines to be continued. The man's countenance is pallid, unhealthy, and anxious.

DISLOCATION OF THE RADIUS.—A little boy was admitted with this injury about four months since under the care of Mr. KEATE. The accident occurred from his being thrown from a pony. He was brought to the hospital about a fortnight after the accident had occurred, and Mr. KEATE first tried to reduce the dislocation over his knee, but failed. Several other attempts were made, by manipulation, and extension with towels, at various times, but all of them failed; and after the boy had been in the hospital upwards of a month, a consultation was held as to the propriety of making further attempts, and decided in the affirmative. The

boy was then ordered to take nauseating doses of tartar emetic, and to be bled. Neither of these directions, however, was complied with, as he left the hospital, though he returned again on the following day. We then examined the arm (the left) and found the radius dislocated backwards, upon the condyle of the humerus, with much thickening of the parts around, some ligamentous adhesions having, probably, formed around the displaced head of the bone, to such an extent as effectually to prevent reduction. Our prognosis was verified on the boy being again brought into the operating theatre. Extension by pulleys was steadily made for five minutes, but the bone did not move. A towel was then passed over the humerus, to hold it as a fixed point backwards, and the fore-arm being half flexed, the bones were drawn away from the joint in a similar manner, while Mr. KEATE, by manipulation and rotation, endeavoured to move the bones, but to no purpose; some ligamentous adhesions were broken down, but the head of the bone did not move from its abnormal situation. A bandage and a bent splint were then put on the arm, and the boy left the hospital with his father.

WANT OF APPARATUS.—We take this opportunity of remarking that there exists no mechanism in the operating theatre for the reduction of dislocations. One staple only was driven into the wall on this occasion, and that proved to be of no use whatever. The physical force of arms, legs, and towels, was therefore employed. Mr. KEATE and Mr. BABINGTON were antagonists to Mr. HAWKINS, but their strength was soon exhausted. The board-room is the spot generally fixed upon for reducing dislocations, but it was the weekly board-day, and it was not deemed advisable to trouble any of the gentlemen who assemble on these occasions, with an exhibition so well calculated to shake their nerves.

CONGENITAL OSTEO-SARCOMATOUS TUMOUR.—A patient was admitted some time since under the care of Mr. Hawkins, with this species of tumour affecting the external condyle of the left ulnar (congenital, so far, we understood), and the first and second phalanges of the ring-finger of the same side. The finger being removed, Sir B. BRODIE observed, that he had met with a precisely similar case, in which the tumour near the olecranon had been congenital, and the tumours of the finger had supervened, as in the present case. The man has gone on well since. He was very restive during the operation, and something more than a common chair was required to restrain him, but was not obtained.

INJURY OF THE ARM.—William Rose was brought into the admission-room, Sept. 18, 40, admitted with

for the care of Sir B. Brodie. The patient's countenance was extremely idiotic, and had the appearance of his having just recovered from an epileptic fit. The only account then obtainable was, that he had been shot in the head, and he was observed to have a drawing back of the head. In consequence of his distressed appearance he was immediately sent to one of the upper wards to bed. On making some further inquiries into the history of the case, it appeared that about a month since he had been shot in the back of the head over the occipital region, and that some of the shot had been extracted by a medical gentleman who attended him. He has now but little power over his lower limbs; the senses of sight and hearing are very much impaired, and he complains of great pain over the whole region of the head. He was immediately ordered calomel and opium.

Sept. 23. Sir B. Brodie saw him to-day, and ordered the medicines to be continued; a blister to be applied over the back of the neck, and kept open by the green savine cerate.

25. He is quite amaurotic, and his sense of hearing is still very imperfect. The drawing back (opisthotonos) of the head, which was very great when he was admitted, to-day is somewhat less; the blister has discharged freely, but by some mistake it has been dressed with savine and mercurial ointment mixed, and this double mercurialization of the system by blister externally, and the calomel internally, has affected the mouth, and his gums are red and spongy. The head was ordered to be shaved, and the present blister to be dressed and healed, and another put on higher up over the occiput, and kept discharging with savine cerate only. The calomel and opium, which had been given three times a day, were ordered to be given only once daily.

Sir Benjamin Brodie remarked that this case was a very interesting one, and requested his clinical clerk to keep an account of it. In all these cases of injury to the brain, in which opisthotonos had been remarked, in which he had witnessed the post-mortem examination, there had been found a collection of pus about the tuberculum annulare and medulla oblongata. "I have seldom (he continued) observed loss of vision in these cases, but as it is now said that the optic nerves can be traced as far back as the corpora quadrigemina (the testes), and as these parts are all situated near one another, it is but fair, I think, to conclude that there is some deposition of pus in this case. I remember one case of injury of the head in which there was loss of sight, and after death, there was found a transverse fracture of the bones at the base of the cranium, and the optic nerves were discovered to pass on the sphenoid bone.

Loss of the other senses may be present after these injuries, without at all increasing the danger or affecting the recovery of the patient. I have known the patient to be stone deaf and recover; and I have known the nerves of taste to be so vitiated, that sweet things would taste sour, and bitter things sweet, and yet the patients have recovered."

Oct. 2. The same treatment is persevered in, and with very good results. The deafness is less and the amaurosis diminishing. The opisthotonos is nearly gone.

Oct. 10. Since our last report he has had rather a severe epileptic fit, the peculiar phenomena of which it baffled the nurse's skill to describe. He was bled, and took calomel and Epsom salts to affect the bowels, which have been very sluggish. The "head" symptoms remain much the same, without any progressive amendment.

20. He has had frequent returns of epilepsy, for the relief of which Sir Benjamin ordered him to be put on full diet for a few days, but without, as may be supposed, producing any sort of influence on the attacks. His other symptoms are much the same,—certainly not better. The sphincters ani and vesicæ are relaxed; as the nurse says, "he does everything under him." Sir Benjamin thinks that the disease is beyond the reach of medicine, and looks to the pathology of the case with interest.

THE refusal of Mr. LISTON to accept the Chair of Surgery in the University of Edinburgh, does not appear to have been by any means satisfactory to the feelings of some of the magnates in modern Athens. In reply to an article which appeared in the *Scotchman* of last week, the *London Courier* evening paper, of Dec. 19, wrote as follows:—

"The notice which our worthy contemporary the *Scotchman* has taken of an article in last Saturday's *Courier*, relative to the recent appointment of Sir Charles Bell to the Chair of Surgery in the University of Edinburgh, as well as the remarks made upon that article in the Town Council of Edinburgh by one of the members, render it indispensably necessary for us to reassert the accuracy, to the very letter, of that part of the article in the *Courier*, in which it is stated that "as soon as it was ascertained, by reference to Mr. Liston, who has lately settled in the metropolis, that he would not forego his prospects in London for any of the medical chairs in the University of Edinburgh," the members of the Edinburgh Council resolved to elect Sir C. Bell.

"Mr. LISTON, we have reason to believe, received the first intimation of its being the

wish of certain members of the Council to bestow the vacant Chair on him, when he was recently in Edinburgh, to which he had been called soon after the death of Professor TURNER, to perform an operation of no trifling description. The truth of our assertion, however, does not depend on verbal conversations, but on the unerring testimony of written documents, which passed between members of Council and Mr. LISTON, and which have been in our hands.

"Sir CHARLES BELL's friends seem to us to have acted injudiciously, and to have shown more sensitiveness than discretion in originating this discussion. Whatever may be the respective merits of Sir CHARLES BELL and Mr. LISTON, we certainly never meant to institute, in the columns of the *Courier*, any comparison between these eminent professional men, either as public teachers or as skilful and able surgeons. We merely stated facts known to us, and whatever might have been our private opinion as to the result of the election, had Mr. LISTON as well as Sir C. BELL been in the field, we neither assumed nor insinuated that Mr. LISTON would necessarily have been elected to the chair, had he been willing to accept it. His decided refusal made the election of Sir CHARLES BELL "the fittest individual, who was willing to accept the situation," unanimous, and of course without opposition.

"We are surprised that the report of the Town Council proceedings on this occasion, does not contain what was said by one of the members of the Town Council, in answer to the speech remarking on the article in this Journal, nor other details of the discussion which we understand took place. We hope that at the next meeting of Council, the Member of Council to whom we have

alluded, will present Mr. LISTON's letter of his declining to be a candidate for the Chair.

In the press, and speedily will be published by John Murray, Albemarle-street, "Oratio ex Harveii Instituto, habita in aedibus Collegii Regalis Medicorum Die Junii 25, 1835, Ab HENRICO HALFORD, Regis et Reginae Medico, praeide."

Clinical Illustrations of the more Important Diseases of Bengal, with the Result of an Inquiry into their Pathology and Treatment. By William Twining, M.R.C.S.L. Second Edition, two vols., 8vo. Calcutta. Parbury and Co., London, 1835.

CORRESPONDENTS.

WE must use the letter from *St. George's Hospital*, respecting the Street School, for our private information. We cannot publish it without permission to append the name of the writer. The anxiety to obtain pupils at new establishments, is not unlikely to lead to many concessions of gratuitous admissions at the outset of their career.

T. H. B. The paper will be inserted. Our arrangements have not hitherto allowed it to appear. In the proposed communications, brevity should, where it can usually be observed.

WE have not yet had time to consider the propositions contained in the letter signed *A Consulting Surgeon*—nor yet to print some long communications from correspondents both in town and country, forwarded for insertion in our columns.

The proposition of a *King's College Student* could not, we are sure, be carried into effect without loss to the *speculator*,—at least not at present. We could cite numerous instances in proof of the correctness of this opinion.

LECTURES ON DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

BY M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE VI.

ANEMIA OF THE BRAIN AND CEREBRAL HEMORRHAGE.

GENTLEMEN,—We have now traced the history of two of the great divisions under which we arrange diseases of the central part of the nervous system, viz., congestion and inflammation. We shall now, therefore, pass to a consideration of the accidents connected with anemia, and then terminate this part of our subject with cerebral hemorrhage, or apoplexy.

Anemia of the nervous centres is a disease which is especially remarkable in this point of view, that it often gives rise to phenomena which very closely resemble hyperemia, and yet it is evidently a matter of the utmost importance to distinguish these two opposite states from one another. In practice, you will frequently have to ask yourselves this question, "Do the functional derangements of the nervous system which present themselves, depend on too great an afflux of blood to the brain, or are they connected with a condition quite opposite, viz., anemia?" It is unnecessary to say, that hyperemia and anemia will require different modes of treatment; let us, therefore, enter into a few considerations on this latter disease; and first, for the

General Characters of Cerebral Anemia.

Anemia of the nervous centre is characterized, as its name would lead you to suppose, by a marked pallor of the sub-

stance of the brain. The gray substance is much more pale than in the normal state; it contains a less number of vessels, and thus approaches in its general appearance to the white or medullary portion of the brain. In some cases the organ looks as if it had been macerated in water for a considerable time; and BILLIARD relates that he has sometimes found the cortical substance of the hemispheres so completely decoloured and pale, that the surface of the brain resembled a mass of modelled wax. The state of the nervous centre just described, may exist alone, or become complicated with other changes of structure. In some cases it has been observed to coincide with a peculiar hardening of the cerebral mass; in others the brain is softened, and does not present its usual consistence; however, we now propose to examine anemia in its simple form, when it exists alone, and without any complication.

Its Symptoms.

Anemia may be confined to the brain itself, or coincide with a similar state of anemia in the rest of the body. Thus we have frequently occasion to observe it after the occurrence of considerable hemorrhages; or it may be a consequence of chronic or acute disease. The influence of the latter cause is often seen in children affected with acute gastro-enteritis, at the termination of which we observe symptoms that seem to announce a state of irritation in the brain, while, on the contrary, the organ is anemic, and presents, after death, an extreme degree of paleness. Sometimes, however, anemia of the brain may occur without any disorders which indicate a diminution in the general quantity of the blood, or a deterioration of its quality. Here the disease is confined to the brain alone, and depends on causes peculiarly influencing the circulation in that organ.

Anemia gives rise to the existence of certain symptoms, whose connection with it as a cause we can prove upon living animals. If we bleed an animal to such an extent as suddenly to deprive him of a large portion of blood, we give rise to a series of symptoms that, under other circumstances, we might easily attribute to excitement of the

nervous system, and the animal is seized with general convulsions, and these become more and more intense in proportion as the brain becomes empty. In the human subject we observe the same phenomena. After traumatic hemorrhage, copious loss of blood in uterine hemorrhages, &c., the patients are frequently attacked with nervous delirium, convulsions, and other symptoms, which we have pointed out when treating of congestion. Hence we establish this general rule, most important in practical application, that a diminution of the normal quantity of the blood gives rise to the same symptoms as hyperemia, or an increased quantity. Look at the digestive organs: a difficulty of digestion coincides equally with an increased injection of the mucous membrane of the stomach, and with an abnormal paleness of this same membrane. In the latter case, as in the former, digestion is troubled, because the organ no longer receives the quantity of blood necessary for the normal accomplishment of its function. In the lungs, dyspnea is equally produced, either by an hyperemia more or less considerable of the pulmonary tissue, or by the fact that the air, in penetrating the vesicles, does not find enough of blood to vivify. In the centre of the circulating system we may observe a similar phenomenon; thus the heart is equally affected with palpitations when it is distended with an over-quantity of blood, and in the opposite condition, when its cavities are imperfectly filled by a poor and impoverished fluid.

These examples we might multiply infinitely. The nervous centres furnish us with a great number. We may therefore, I say, lay it down as an established principle, that the brain, like the other great apparatuses, presents specific symptoms when it ceases to be stimulated by the normal quantity of blood. Let us briefly enumerate these symptoms. They are, 1st, Those connected with the intelligence. Delirium is a common symptom of cerebral anemia. Dr. PAPAVERNE, an ex-interne of the *Hopital des Enfants Malades*, has published several cases of children affected with the most violent delirium, and dying in this state. After death no other lesion could be discovered in the brain, except a complete decoloration of the gray substance which appeared confounded with the white.* We observe the same delirium in persons accidentally submitted to a forced abstinence, or in patients weakened by a former malady, and kept on too severe or prolonged a diet. In these cases we observe functional disorders, resembling closely those depending upon congestion, but certainly in no way connected with that state, for they gradually disappear as the blood is regenerated, and under the influence of a generous

and wholesome alimentation. Examples of this kind are chiefly seen in children, or in individuals endowed with what is called a nervous temperament. You have already seen how hyperemia and inflammation of the brain are often produced by increased stimulation of that organ. We may produce the same effects, or, rather, give rise to the development of exactly similar functional disorders, by withdrawing the quantity of any stimulant to which the brain has been accustomed.

A remarkable case of this kind has been published by a German physician, Dr. HANSERANDT. It illustrates perfectly the point we have just advanced:—A man, given excessively to drinking, was thrown into prison for theft, and of course reduced at once to the prison diet, bread and water. After a week or two living in this new fashion, the intellectual faculties of the prisoner commenced to show some symptoms of trouble; his strength and flesh declined at the same time; finally, he was seized with delirium, which, at first tranquil, became afterwards more and more furious; the patient cried out from time to time in the most agonized manner, and thought he was constantly surrounded with horrible figures. The physician called to attend him in this dangerous state, having informed himself of his previous habits, suspected that the cause of his mania and other symptoms consisted in the abstinence from spirituous liquids which he was compelled to observe; he therefore ordered a small quantity of brandy to be given twice a day; the effect of this change of regimen was soon obvious; the cerebral accidents gradually disappeared, and the patient recovered his flesh and strength, and continued to enjoy perfect health during the remaining period of his detention.*

The faculty of movement is also more or less disturbed, in consequence of cerebral anemia; thus, we have already noticed the convulsions which supervene after copious hemorrhage, or in animals from whom a large quantity of blood has been designedly abstracted. The sensibility is sometimes modified in a remarkable manner; the least stimulant produces effects infinitely more rapid and energetic than we observe in the normal state of the economy. In several cases of anemia, it is not rare to see a marked exaltation of sensation. If we place a blister on the skin, the sensibility is awakened at once, acute pain is produced in the part, and the whole system partakes of the excitement. This is a point to which you should pay attention in practice. When your patient's strength has been considerably reduced by sanguineous emissions, be particularly cautious and reserved in the employment of cutaneous stimulants; a

* Journal Hebdom. de Médecine, Dec. 1825.

* Journal des Progrès, Dec. 1825, p. 349.

single blister, a stimulant may be enough to produce a degree of local disturbance or general excitement which you may have great difficulty in mastering.

Treatment of Anemia.

We have now laid before you the prominent characters of anemia as connected with the central organ of the nervous system. It remains to say a few words on the treatment of this disease. The analogy between the symptoms of hyperemia and anemia has been frequently alluded to. Your first care must, therefore, be to distinguish between them. Having once satisfied yourselves that the nervous symptoms under which the patient labours, depend not upon congestion of the brain, but on anemia, the indication is a very simple one. You must employ every means in your power, by which the normal quantity and quality of the blood may be restored; in a word, you must make new blood. Be careful above all things not to attribute the phenomena of cerebral anemia to any other cause, or you may commit the most fatal errors in practice. Thus, for example, when a patient in the last stage of typhus fever, after twenty or thirty days' suffering, after strict abstinence &c., is seized with delirium and other cerebral symptoms, are we at once to conclude that he has congestion or inflammation of the brain? Certainly not. Support your patient under these circumstances with moderate cordials, light nourishments, &c., and you cure. Bleed him, and you hasten the fatal termination.

CEREBRAL HEMORRHAGE.

We have now studied several morbid conditions of the brain; we have next to take up a subject to which more interest is attached than perhaps to any of the questions that have hitherto occupied our attention; we have to investigate the nature, symptoms, and treatment, of cerebral hemorrhage. This disease, as you know, has been long known under the name of *apoplexy*, a term employed to indicate a sudden loss of motion, sensibility, and intellect, supposed to depend upon effusion of blood into the brain, but I think that

We cannot preserve the word "Apoplexy" any longer in the Science.

It is too vague; it does not indicate with precision the material change in the organ, but, like all other similar terms capable of various interpretations, it lends itself to every theory, and in the end serves no real purpose but that of covering our ignorance. But observe how many different affections of the brain give rise to the same symptoms, *viz.*, sudden loss of consciousness, &c. See how the effects of simple congestion, of cerebral softening, of cerebral emolliement, &c., are equally covered under this generic term.

On the other hand, hemorrhage into the substance of the brain (the essential anatomical character, remark, of apoplexy) may take place without producing the ensemble of symptoms compressed under the word apoplexy. Thus we may have hemorrhage of the brain without loss of intellect. We may observe loss of intellect, and derangement of sensibility, while motion remains intact. You will see this presently. We therefore, I say, must reject the term apoplexy from medical nomenclature, because it refers to various forms of injury in the brain. We reject it, because it represents identical symptoms depending upon various and quite different causes.

Situations of Cerebral Hemorrhage.

Hemorrhage of the centre of the nervous system may occur at any point of the cerebro-spinal axis. However, it has been observed more frequently in the substance of the hemispheres than in any other part. Again, there are certain portions of the hemispheres which seem much more subject to this accident than others. Thus, from an examination of a large number of cases of cerebral hemorrhage, we find a great majority to take place in the nervous pulp, on a level with, and outside of, the corpora striata and optic thalami. One or other of these latter parts may be attacked in an isolated manner, or both together; but it would appear that the striated bodies are much more subject than the thalami to effusions of blood. Again, the hemorrhage may exist beyond the points we have just mentioned, or in the mass of nervous matter called centrum ovale. Finally, in some cases the effusion of blood does not take place in the interior of the brain, but at its surface. The blood is shed between or on the convolutions, and then represents an uniform layer, spread over an entire hemisphere; or it may be confined to a single lobule.

There are, again, other parts of the cerebro-spinal axis in which effusion of blood may take place, but much less frequently than in those we have now spoken of. Thus, hemorrhage occurs in the substance of the pons varolii, or in the prolongations which it sends off to the cerebrum or cerebellum; or, finally, in the substance of the latter organ itself. Apoplexy of the cerebellum is, however, a very rare disease, and here, as in the cerebrum, the effusion may have its seat in the median lobe, or in one of the lateral hemispheres. The medulla oblongata also presents us with examples of hemorrhage, and the spinal column in any one point of its extent.

The central parts of the brain, properly so called, are much less frequently the seat of hemorrhage. Thus it has been observed but seldom in the inferior part of the centrum ovale, and in the septum lucidum in

particular. Authors sometimes speak of another species of hemorrhage, viz. that which takes place in the interior of the ventricles; but these also are rare. We certainly find blood effused into the cavity of the ventricles in many cases of apoplexy; but if you examine with care, you will find the blood has made its way from the nervous pulp surrounding them; or, for example, when the septum lucidum is broken down, the blood may traverse that space, and pass into the other ventricle; both cavities will then appear full of blood, but there is almost always a communication between them and the accidental cavity formed by the effusion of that fluid into the substance of the brain. The hemorrhage may take place in the tissue of the pia mater, which envelops the cerebral convolutions. This form of effusion has been called by M. SERRES "meningeal apoplexy;" it is a very rare variety, and when we have occasion to observe it, we generally find at the same time an effusion of blood in the brain. The fluid finds its way into the membrane from the apoplectic cell, in the same manner as it does into the ventricles. Sanguineous effusions into the centre of the nervous system differ considerably in extent in different cases. Sometimes the cell is excessively small: so insignificant that it would scarcely contain a pin's-head. In other cases the hemorrhage has been abundant: the cell is vast, and occupies nearly the whole of the hemisphere. The number of these apoplectic cavities is as various as their extent; we may find but a single one; sometimes two or more. In some cases, on the contrary, the brain appears, as it were, riddled with an immense number of these hemorrhagic cavities, which have been formed either at the same time or successively, one after the other. Certain effusions of blood exist frequently alone; for example, those seated in the different parts of the hemispheres; but others, on the contrary, do not occur unless we have effusion somewhere else. Thus in by far the greater number of cases where blood has been found effused into the substance of the cerebellum, an hemorrhage has at the same time been discovered in some one part of the cerebrum; and this is perhaps one of the principal reasons why apoplexy of the former organ is so little known, why we are so imperfectly acquainted with the history and symptoms of hemorrhage of the cerebellum.

The Appearance of the Effused Blood

varies much, according as we have occasion to examine it at a period more or less removed from the instant of its effusion. In recent cases, the blood is generally of a blackish colour and liquid consistence; at a later period, it resembles currant jelly, surrounded by some blood still quite fluid. Still later it becomes more solid, yellowish, or

whitish, and at length loses entirely its normal colour and appearance. If we seek

The Source of the Hemorrhage.

the part from which the hemorrhage takes place, we find two different sources. 1st. In some cases it is effused from the capillary vessels, and on examination we are unable to determine the exact point whence it has proceeded. 2nd. A vessel of some magnitude may have been ruptured, and given rise to the effusion. In this latter case, we can frequently discover the injured vessel on the surface of the apoplectic cavity, but it is right to warn you that in some other cases the ruptured artery has been found very far from the neighbourhood of the effusion, with which it is connected by a pedicle that might easily escape notice.

The Blood once Extravasated from its Vessels, what becomes of it?

This is a question of some interest in the history of apoplexy. It may remain unchanged until the death of the patient, or, under other circumstances, it may gradually diminish, and eventually become absorbed. In this latter case nature performs an extraordinary and beautiful operation, which commences with the removal of the effused blood, and terminates in the cure of the patient. We have already noticed the changes that take place in the blood contained in an apoplectic cavity. At first dark and fluid, it gradually loses its colour and consistence, from the absorptive of the more fluid parts. At length we find that nature has prepared an apparatus for its more complete removal. The coagulum is now contained in a rounded or irregular cavity, whose parietes are lined by condensed cellular membrane, forming a yellowish cyst, very analogous to a serous cyst. This cyst secretes a kind of serous fluid, whose use appears to be to penetrate the coagulum, separate the different parts of the blood, and render it more easily absorbed. Still later, upon examining the cyst, we find nothing but serum or a gelatinous fluid in its cavity. The parietes are connected together by a number of fibrous bridges that pass from one side to another, and intercross in various directions. The effused blood is now completely absorbed, but nature does not rest here; she now commences the task of removing the cyst; and the latter having enjoyed for a certain time its provisional existence, is gradually effaced, until no trace remains of the original accident, except a simple linear cicatrix, or a cicatrix with puckering and depression of the cerebral substance.

It was only within the last few years that the series of transformations we have now briefly described were followed up in a connected manner, by Messrs. RIGAUD, BOURG, and others, although the possibility of linear cicatrization in the brain was known, and the process alluded to, two centuries ago.

A modern author, however, has distinguished two ways in which the blood may be affected with regard to the nervous substance. He has sought to establish two forms of cerebral hemorrhage. In one there is laceration of the brain, with a greater or less loss of substance. In the other, the cerebral pulp is not injured; the blood is simply effused between two layers of the cerebral fibres. In the first case, accompanied by laceration, where the nervous substance is completely broken down, we may ask ourselves if the nervous pulp can be so far reproduced as to transmit volition &c through the injured part. Dr. FOVILLE thinks not. But the possibility of such a regeneration seems established by the experiments of M. SERRES. Besides, do we not know that a divided nerve may unite, and continue to transmit nervous influence as before the injury took place?

Period when Cicatrization is completed.

We cannot lay down any fixed rules upon this point: the time varies considerably in different cases; sometimes the process of cure is very rapid, at other times it is tediously prolonged. In some cases, after a lapse of five or six months from the first appearance of cerebral symptoms, we find that the coagulum has been removed, and nothing remains but a trace of cicatrix: in other cases, on the contrary, the serous cyst of which we have spoken has been found many years after the occurrence of the original accident.

We have hitherto been occupied with the contents of the apoplectic cell, and the manner of its removal. Let us now examine the

State of the Brain in the immediate vicinity of the Effused Blood.

The vessels may present nothing particular, or have undergone an important modification which it is necessary to mention. In several cases of cerebral hemorrhage we find the vessels ossified in a high degree, or so friable, that the least effort is sufficient to rupture their parietes; and you know that in aged persons, who are peculiarly subject to sanguineous effusion of the brain, this state of the vessels is very common. The vessel may give way on the wall of the apoplectic cell, or at a certain distance from it, and in that case the hemorrhage may result from the rupture of a great vessel on the surface, or at the base, of the brain. M. SERRES has seen a case produced by the rupture of the basilar artery, not far from its bifurcation: the blood here made its way into the ventricles. The nervous pulp itself may present certain alterations in or around the apoplectic cell. It may be absent, or we may find it broken down, lacerated, and presenting no other trace of organization than some kind of vascular tissue. Now we may ask, is this ramollissement pre-existence, or was it consequent to the hemor-

rhage of the brain? I am inclined to think that in a great many cases the effusion of blood is preceded by a certain degree of softening of the nervous pulp. The proof is this,—in many cases we can follow, in the softened portion of the brain, all the degrees by which a simple injection of blood is transformed into a more or less extensive effusion: we see the latter commence by a number of small red points, which gradually unite, multiply, and enlarge, to form, in some other portion of the softened mass, a true apoplectic coagulum. However, we should distinguish this species of ramollissement from others of a decidedly inflammatory origin.

Let us now examine the state of the nervous tissue around the seat of the hemorrhage. In some cases the cerebral substance immediately around the cell may be in its normal state, but this is rare; in others the pulp is more or less coloured and injected, and bears marks of having been the seat of irritation. In other cases, again, the coloration of the nervous pulp seems to depend entirely on imbibition of the blood: the parts surrounding the coagulum are the seat of a true ecchymosis; hence it may present a great variety of colours, bright red, red, pale, yellow, &c., according to the vicinity of the cell, in a word, the cerebral substance may present all the shades of coloration which we observe in ecchymosis of other parts of the body.

The nervous tissue surrounding the effusion may be in a state of true ramollissement. This change, as M. LALLEMAND has demonstrated, may take place before the effusion, or it may succeed it, and then give rise to quite another order of symptoms. When the effusion is recent, the nervous substance around it may present several modifications: it may, as we have just remarked, be more or less softened; it may be infiltrated with purulent matter: finally, in some cases, we find a very considerable induration, which many authors attribute to chronic inflammation, in the immediate vicinity of the apoplectic cell.

Let us now leave the environs of the effusion, and consider the

State of the Cerebral Mass in general.

We frequently find in the brain, marks of very considerable congestion, and this is a circumstance of importance to observe, for many of the subsequent symptoms depend more upon the degree of hyperemia which thus occupies the nervous centre, than on the actual hemorrhage itself. As the work of cicatrization goes on after the absorption of the coagulum, this congestion may be repeated at uncertain intervals, and it requires the utmost care and watchfulness on the part of the physician. When very considerable hemorrhage has taken place into the substance of the brain, the opposite

hemisphere to that affected may also become compressed, and that in two different ways. 1st. By the congestion of one hemisphere, giving rise to an increased bulk, and acting directly upon the other, which it compresses. 2nd. By the passage of blood through the lacerated central parts, from one hemisphere to the other. These circumstances have an influence on the appreciation of the signs of cerebral hemorrhage, and are therefore not to be neglected.

Now let us inquire in what state do we find the membranes? They may remain altogether intact, or be infiltrated in a greater or less degree with blood, serum, &c., and thus become a source of complication of the symptoms. When the hemorrhage is of long standing, the membranes may exhibit other lesions connected with the duration of the primary affection. Thus the pia mater covering the convexity of the brain, may be infiltrated with serosity: or we may find a very considerable quantity of serum in the ventricles: this latter is a case which we sometimes meet with in practice. A patient has been attacked, perhaps several years ago, with apoplexy: the first symptoms pass off, but a new set is slowly developed. You now recognise chronic hydrocephalus. The patient dies, and on the autopsy you find, together with the traces of an ancient effusion of blood, a considerable quantity of serous fluid in the ventricles of the brain. We have now to occupy ourselves with

Causes and Times of Cerebral Hemorrhage.

But here our task is short. They are the same as for cerebral congestion; the only differences depend upon different degrees of intensity, and varieties connected with individual peculiarities. We shall therefore refer you to what has been said during the lecture on congestion, merely adding now and then a supplementary remark. You remember that we studied at some length the influence of temperature on the development of cerebral congestion. We have made a similar statistical investigation for hemorrhage of the nervous centre, and found that it is more common in winter than during any other season of the year. Thus of 177 cases which we examined with this view, we found that 60 occurred in winter, 42 in spring, 40 in autumn, and only 35 in summer. You see, then, that the disproportion between summer and winter is very considerable.

We have also asked ourselves whether cerebral hemorrhage is not more common at certain periods than at others: we cannot doubt this. From a statistical calculation made in London by HARRISON, it would follow that during the 17th century apoplexies went on gradually increasing from the commencement of the century to the middle; acquired greater intensity after that period; and became more and more fre-

quent towards the end, when they had attained their maximum. A similar calculation was made in Paris, during the same time, on a very large number of cases, and gave an exactly similar result: the number of cases towards the end of the century exceeded that observed towards its commencement, in a very remarkable manner. Here you see an example of what we stated in our introductory lecture, that diseases of the nervous system are influenced by the different circumstances under which man is placed in society at different periods. What we have just said establishes the greater frequency of cerebral hemorrhage in latter times than at a period not so very far removed from the present. We have now to consider the

Influence of External Agents in its Production.

With respect to this point we have little to add to what has been already said in the lecture on congestion. We shall only subjoin, by way of supplement, that the abuse of spirituous liquors, and the frequent administration of narcotics, are often causes of cerebral hemorrhage, as well as of congestion. Another question is the following: What influence do the different states of the nervous centres exercise in the production of cerebral hemorrhage? May they be regarded as an exciting cause? Certainly, different acts of the brain, such as powerful emotions, violent passion, excessive head-pain, acting upon the central nervous organ, — all these may produce apoplexy. However, we shall add, that simple congestion and its symptoms, without effusion, are more frequently the effect of the causes just mentioned, than actual hemorrhage into the nervous substance.

The Influence of the Digestive Organs in the Production of Cerebral Hemorrhage.

is the next point we have to consider but here we can only repeat a remark which we have just made; derangements of nutrition act in the same way for hemorrhage as for congestion; they may become a cause of either disease; however, they rarely produce actual effusion of blood in the brain, unless the individual has been predisposed to this accident by an original peculiarity of constitution. We have next to examine the

Influence of the Circulation.

Some authors have endeavoured to show that any considerable diminution of the caliber of the aortic arch cannot take place without exercising a corresponding influence on the brain, and favouring the development of apoplexy. This is possible, but I do not know that it has been established in any thing like a satisfactory manner. We are not without examples in the occurrence, of the more or less complete ob-

teration of the great vessels of the heart. We have, indeed, a certain number of cases in which the arch of the aorta was completely obliterated below the point from which the great cephalic arteries are given off. The records of medicine furnish us with four authentic cases. Now out of these four we find only one, a single one, of a corresponding influence having been exercised on the brain; it is that published by Dr. REXNAC, of an individual, ninety-two years of age, who died presenting the symptoms of hemiplegia of the right side of the body. On examination of the body after death, traces were found of an old effusion into the substance of the hemispheres, and the arch of the aorta was found completely obliterated below the origin of the left subclavian artery. This is the only case we are acquainted with showing the connection between an apoplectic attack and diseases of the aortic arch, by which its caliber is diminished. In the three other cases of this kind nothing similar occurred: the brain remained intact, notwithstanding the existence of an organic change by which we might naturally suppose that a great quantity of blood would be determined to the organ. I next mention a case in which the carotid arteries were nearly completely obliterated, and where, of course, the impulse of the circulation in the brain was greatly diminished; yet the patient died of apoplexy. This case destroys the influence of the fact we have just noticed, and, on the whole, it may not be too much to say that the partial aorta attributed by writers to diminution of the aortic caliber in the development of apoplexy, has been excessively exaggerated.

As to the influence of any changes that may take place in the venous circulation, we have nothing new to add to what has been already said on congestion. The causes of the one act equally in the production of the other, though perhaps with a less degree of intensity. It is not often that we see cerebral hemorrhage produced by a simple interruption in the venous circulation, although, as we have had occasion to remark at another time, that the latter cause frequently produces a greater or less degree of congestion. This fact has been submitted to the test of experience. Several physiologists have endeavoured to determine how far a sudden interruption of the venous circulation from the head may influence the development of apoplexy: they have tied the veins which bring back the blood from the centre of the nervous system, but in most cases have not succeeded in giving rise to the expected accidents. The ligation of the great jugular veins has been performed without giving rise to any symptoms of apoplexy, or even of hemorrhage.

Has there been in the constitution any influence in the production of cerebral hemorrhage? Certainly it is impossible to deny

that individuals presenting the character of what is called the sanguineous temperament, are sometimes attacked with hemorrhage of the nervous centres: this is a fact that no practical physician can deny. However, we are compelled to observe that it gives rise more frequently to congestion than to effusion of blood in the brain. Perhaps the most correct point of view in which we can regard it is, as a predisposing cause. We have seen more than one case where the subsequent attack was long announced before its occurrence, - where the hemorrhage was predicated from the temperament of the patient, and the prophecy unfortunately fulfilled: in short, it is impossible to deny the connection between apoplexy and that state of the constitution in which the individual presents the character of having an excess of blood. However, in many other cases, the effusion of blood into the brain takes place in quite an opposite state. Many patients of a pale appearance and exsanguineous temperament, have been equally attacked by the disease now under consideration. Hence the absence of a plethoric temperament by no means guarantees against an attack of apoplexy. Indeed a case has been published in which the patient was struck with cerebral hemorrhage at the very moment he had lost a large quantity of blood from another source; the state of general anemia was here unable to counteract the tendency to effusion in the brain, which took place at a time when we cannot certainly suppose any great impetus of blood towards the cerebral organ.

Some authors have spoken of the occurrence of hemorrhage in pregnant or lying-in women. They consider the act of accouchement, and the state which precedes it, as exciting causes of apoplexy; but the cases of cerebral hemorrhage during labour are rare, very rare; if there existed any real connection between apoplexy and labour, we should observe the former much more frequently than we do. The number of lying-in women is, as you know, immense; the cases of cerebral hemorrhage during accouchement are few; hence I think its occurrence at that period completely accidental, and not to be attributed to the state of the system in childbirth. In some women the hemorrhage takes place within the first few days after accouchement; here, also, for the reasons which we have just given, we think the apoplexy is a mere coincidence.

Is the Influence of the Sex felt in the Development of Cerebral Hemorrhage?

Are males more subject to this disease than females, and if so, in what proportion? JOSEPH FRANK used to say, "inter decem apoplecticos unam numerare soleo feminam." But this proportion is much exaggerated; apoplexy is a disease more frequently seen in females than you may be

led to expect from the aphorism of FRANK; indeed, any of you who have been in the habit of attending at *Salpetriere* must be already aware of this. JOHN PETER FRANK published a statistical account of 1241 cases of apoplexy observed at Vienna, in which the sex of each individual was noted. Of these 1241 cases, 637 occurred in persons of the male sex; the remaining 604 were females. Here, you see, is a great difference, from the result of JOSEPH FRANK'S observations. A French physician, M. FABRET, has made a similar calculation on a larger scale: he has collected 2297 cases of cerebral hemorrhage, and found that 627 of the individuals so attacked were women. This proportion, again, differs sensibly from that of PETER JOHN FRANK, but is far from approaching the relation of one in ten, laid down by JOSEPH FRANK. The next point we have to examine is, the

Influence of Age

in the production of cerebral hemorrhage. Are apoplexies more frequent at an advanced period of life than at any other? Certainly so; the result of investigations made by M. ROCHOUX, and others, have placed this beyond any doubt, and show that after the age of 50 these hemorrhages become common, and acquire their maximum of frequency in a period between that and 70 years of age. In childhood and up to the period of 35, they are rarely observed. These results are perfectly in accordance with the aphorism of HIPPOCRATES, which indicates the greater frequency of cerebral hemorrhage at an advanced period of life. M. ROCHOUX, in particular, has occupied himself in the solution of this question. He has made a relevé of 61 cases, and found them distributed in the following order, viz. from 30 to 40 years of age, 10; from 40 to 50, 7; from 50 to 60, 13; from 60 to 70, 24; from 70 to 80, 12; finally, between the age of 80 and 90, he observed only a single case. The conclusions at which he arrives from the above numbers is, that the maximum of cases of apoplexy occurs in the fifteen years which are comprised between 55 and 70; that after this latter period the tendency to cerebral hemorrhage seems to diminish; and, finally, that it is equally rare before the age of 30 or 35 years. The rare occurrence of cerebral hemorrhage at the two extremities of life seems thus established; however, we are not without examples of apoplexy at a very early period of existence. I myself saw a young boy, thirteen years of age, who died rapidly under the symptoms of effusion of blood in the brain; after death I found an enormous coagulum in one of the hemispheres. M. BRUNET gives the case of a child, four years of age, who died in a similar manner. SENN has published one that occurred in a child three months old; and,

finally, M. BISHOP, in his work on the diseases of children, speaks of an infant who died in an apoplectic state three days after birth. On examining the body, an effusion of blood was found in the left hemisphere of the brain, near the corpora striata.

We shall continue the subject at our next meeting.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE II.—DISEASES OF THE KNEE-JOINT.

Termination of former Cases of Disease of the Hip-Joint.—At our last meeting, gentlemen, I detailed to you the history of four cases of disease affecting the fibrous capsule of the hip-joint, giving the progress of each case up to the date of the lecture, all of them, with the exception of one case at that period being in the house. The third patient, a boy, had been presented cured at the time I delivered my remarks, and since then two of the other patients have likewise left the hospital. The patient in the second case, Septimus Carter, in whom the local disease was complicated with febrile symptoms, though not yet perfectly well, left the hospital by his own desire, that he might have the benefit of a better atmosphere than he could obtain here, as he resides at a short distance from town. He has now but very slight pain, either of the knee, or of the hip upon pressure in the groin; he can move about with tolerable freedom; in fact, his sufferings are hardly to be considered of any importance, and I am sure that by rest, and improvement of his general health, if he be not guilty of some imprudent act, he will gradually recover.

The fourth case was that of a woman in Queen's Ward; and in this instance I have not so favourable a report to make. She was twenty-six years of age, a housemaid, and the mischief had arisen in consequence of a severe blow from a fall. Although the report states that the secretions have been pretty regular, yet there has been something wrong, constitutionally, which has influenced the local complaint. Her general health does not appear now to be so good as when I last met her, and I think you will generally find that in proportion as the general health improves, the knee does,

he will the local affection be retrograde. To-day she complains of pain in the hip upon pressure being made over the anterior part; but when pressure is applied over the posterior part, she feels a kind of soreness merely. The pain of the knee is not constant; it occurs at night, and upon pressure on the anterior parts. The uterine functions are regular. She has not a good appetite, though the secretions are good and regular. I have given her, in consequence of there being a diminution of the general powers, the *mistura potassæ hydriodatis*. We have applied a fresh moxa to the joint, and I trust at our next meeting I shall be able to give you a more gratifying report. However, so far as all these cases go, they show well the nature of disease of the fibrous capsule, and that the plan of treatment which has been resorted to is likely to be efficacious in the majority of such cases, three of the four cases having been cured, and the remaining case being nearly so.

I shall this morning direct your attention more particularly to cases of disease of the knee. I should have liked to pursue the subject of disease of the hip farther, had I had cases in the house to illustrate how disease affecting that joint attacks the synovial membrane, the capsule, and the cartilages, proceeding to abscess, destruction of the cartilages, and, occasionally, to dislocation; but having no such cases, and desiring to keep these clinical remarks as closely connected as possible with cases under our guidance at the time they are delivered, I shall proceed to speak to you of diseases of the knee.

CASE 1.—Inflammation of the Synovial Membrane of the Knee joint, with Increase of its Secretion.—The first case I shall advert to is one of inflammation of the synovial membrane of the knee-joint, with an increase of secretion from inner surface of that membrane. It has occurred in Thomas Clarke, a carpenter, aged 23, of temperate habits, residing at Kennington. He was admitted into No. 8, Abraham's Ward, on the 22nd of October last. Upon his admission he stated that about twelve months ago, being in the habit of kneeling very much in his business, having been planing boards for floors, he observed a slight swelling of the right knee, unattended by pain, except on exposure to cold. The swelling gradually increased, and more particularly so upon taking much exercise. He had gonorrhœa about two years and a half ago, but the discharge had disappeared about a year and a half before the appearance of the present malady. My inquiries were directed to this point for a reason which I shall presently mention. Upon his admission he complained of occasional pain, increased at night, of a dull aching character, aggravated by motion of the joint, and pressure

between the inner condyle and the patella, or between the internal lateral ligament and the patella; also upon pressure between the ligamentum patellæ and the external lateral ligament. The synovial capsule was distended, and puffed up with fluid, more particularly apparent in the parts I have described, and at each side of the tendon of the rectus. The general health was tolerably good. He was directed at that time to keep his bed, that the limb might be quiet, and a blister was applied to the surface.

On the 27th it says the pain is now of a sharp darting character, occurring at intervals only; and that it may be produced by pressure over, or by motion of, the joint. The swelling is much less. The blister healed under the application of a simple poultice, and another blister was directed to be applied.

31. Pain less, and he can move the joint without increasing the pain.

Nov. 4. Scarcely complains of any pain; swelling nearly gone; rests well at night; appetite good, and secretions regular.

11. No pain on pressure, or motion of the joint; swelling subsided; general health good; secretion regular; presented cured.

Anatomical Structure of the Knee-joint.—As all my remarks to-day will refer to mischief to the knee articulation, perhaps I may be excused in the outset in offering a few brief remarks on the anatomical structure of that part, as our diagnosis must depend a good deal upon examinations conducted on anatomical principles.

This articulation, then, admits of motion in two directions only,—flexion and extension, as they are commonly called; and, consequently, this joint is placed among the anguloid, or hinge-joints. The joint is formed principally between the lower part of the femur, and the upper part of the tibia, with an interposition of fibro-cartilaginous bodies, which aid in forming the joint, and are termed the semilunar cartilages, from their figure. The motions of the joint are restricted principally by bands of fibres termed ligaments—a very strong one on the inner, and two on the outer part; and these are termed the internal and external lateral ligaments. We have, further, a portion of the tendon of the large rectus muscle proceeding from the thigh over the patella, improperly called the ligamentum patellæ, which should be regarded, however, as a continuation of the tendon of the rectus. This is placed more distant from the joint than any we have described, or have to notice, a quantity of fatty matter being placed between it and the synovial tissue. We have abduction, or a throwing of the leg outwards from the femur, prevented by the internal lateral ligament, and we have the motion of turning it inwards prevented by the external lateral ligament. We can

flex the leg to a considerable extent, but can only extend it to little more than a straight line with the thigh. The further extension is prevented by the posterior ligament of Winslow, which is considered by some as a continuance of the semi-membranosus, which contributes to form the inner ham-string. Besides, we have on the inside, two firm bands of ligament, proceeding from before and behind the rough protuberance of bone, on the middle of the articulating surface of the head of the tibia, to the condyles of the femur; and these are called the crucial ligaments, from their being placed across each other. These ligaments perhaps assist in preventing extension of the leg beyond a certain degree, but they will very much prevent rotation of the condyles on the head of the tibia; that is to say, if you attempt to twist the thigh inwards or outwards from the leg, the anterior and posterior crucial ligaments, aided by the other ligaments I have enumerated, will restrict such motions. These are the principal ligaments for the protection and limitation of the motions of this joint; there are some others, but their importance scarcely requires us to occupy our time in adverting to them; nor is it necessary that I should describe to you at present the small ligaments which connect the semilunar cartilages, for they are out of reach when we are called upon to examine the joint.

Now the synovial membrane is within all these ligaments. It covers the articular extremities of the bones, and passes some distance up in front of the thigh-bone, beneath the tendon of the rectus or quadriceps muscle. There is a little interruption, however, to the strict continuity of the surface of the synovial membrane; that is to say, it does not form a perfect sac, because of the attachment of the little process termed the ligamentum mucosum, which proceeds behind the ligamentum patellæ to the condyles, just in the same way as you have the ligamentum teres proceeding from the hip-joint, to be attached to the femur, although nothing like so strong a ligament.

You will find, then, that there are ligaments on the inner, the front, the outer, and the posterior sides of the knee-joint, and that the synovial membrane is necessarily more exposed between any of those particular spots, than where it is covered by the ligaments; this is the case more especially on the anterior part of the joint, where no muscles pass over it, so as to assist in protecting the membrane. In many of the books which treat of the ligaments and articulations, there is no mention made of the fibrous capsule of this joint; but, in strictness, there certainly is a fibrous capsule covering the articulation, although not so distinct or so defined as that of the hip-joint. Thus we have a fibrous expansion, connected with the synovial membrane, be-

tween the respective ligaments which I have described. It is only where there is a greater assemblage of fibrous bands, and where these are more distinct, that they have been divided into separate portions, under the name of "ligaments."

Diagnosis of the foregoing Case.—Well, now, I have mentioned that in the case before us there is inflammation of the synovial membrane, with increased secretion of synovia. How is this distinguished from any other disease? Perhaps when I have related some other affections of the joint, you may understand it better; but, in the first place, I may state that the mere swelling, and the shape of the swelling, were sufficient to satisfy me that it was the disease which I have described, and that it was within, and not external to, the capsule. The swelling appeared on either side of the tendon of the rectus, and a little likewise at the side of the ligamentum patellæ. There is no particular enlargement corresponding to the situation of any of the ligaments. The joint, when examined by touch, gives an impression of elasticity, indicating that the tumefaction arises from the presence of fluid, rather than from solid deposit; and we come at once, therefore, to a knowledge of the disease. But on going into the history of the case, we find that it has been produced by injury. Injury is a great deal more likely to produce disease of the fibrous tissue than of the synovial membrane. The patient has pain, and that pain is increased at night. Now when we look at the intimate connection which exists between the fibrous and the synovial membranes, we cannot wonder that the one should participate in the diseases of the other. It is very rarely, therefore, that we have isolated affection of one of those membranes. We are much more likely to have isolated affection of the fibrous than of the synovial membrane; because the vessels supplying the synovial membrane, pass to it from the fibrous membrane, therefore when disease is set up in the synovial membrane, it extends rapidly to the fibrous capsule. Just so should we find it in the case of inflammation of the dura mater. Seldom does it happen that we have inflammation of the dura mater, without the inflammation extending to the lining membrane. So, again, in pericarditis, the inflammation of the pericardium extends to the serous membrane, and terminates in adhesive deposit. Besides, as to the nature of this swelling, I found that the patient did not suffer much pain when I made pressure over the ligaments, but when I came to make pressure over the parts where the synovial membrane is much exposed, the pain was considerable, and that was an additional reason to satisfy my mind of the nature of the disease.

This is not a very common affection,

either as an idiopathic disease, or as the result of injury, for injury more frequently produces affection of the fibrous structure. I was therefore induced to inquire into the probability of there being any specific cause of the affection; for the disease, as we very well know, which is generally called "gonorrhoeal rheumatism," affects particularly the synovial membrane of articulations. I have been consulted lately upon a case very illustrative of this kind. A gentleman has been for some years the subject of disease of the urethra; and in spite of all he has suffered, he will go on subjecting himself to fresh attacks of disease, and almost as often as he is imprudent, so often has he gonorrhoea. As soon as the inflammation is set up, and almost as soon as the purulent discharge is established, he has affection of the different articulations; the synovial membranes become inflamed, they pour out secretions, and the joints become tumid, just as in the case before us. So that this disease, you will observe, is frequently connected with a gonorrhoeal, or what we may call, if you please, a venereal taint. I therefore made inquiries in the present instance, and proceeded to examine the urethra, to ascertain if there was stricture; and at last, being satisfied upon all these points, and that the disease originated from pressure, and not from any specific influence of this sort, the treatment became simple; mere rest, with counter-irritation, having at once annihilated the disease. A couple of blisters were applied, he recovered the power of motion, without suffering, and was enabled to quit the hospital, in ten days or a fortnight, perfectly well.

CASE 2.—Inflammation of the Synovial Membrane of the Knee-joint, with deficiency in its Secretion.—We have another case, where there is inflammation of the synovial membrane, with a deficient secretion of the synovia, there being an increase of the secretion in the last case. Elizabeth Herring, aetat. 14, a housemaid, was admitted on the 19th of the present month into No. 7, Lydia's Ward. She states that about a month ago, after kneeling, a swelling formed over the ligamentum patellae. Probably she had the disease called the "ganglion patellae." The swelling was attended with much pain; and the joint became more painful towards night. Motion produced rather severe pain. Leeches had been applied previous to her admission, without any benefit whatever; she had been going on in the discharge of her duties as a servant during their application. Upon her admission she complained of sharp darting pain on the inner side of the knee. Pressure on the inner condyle produced severe pain. Any motion of the joint was attended with crepitus, and aggravation of her suffering. Over the ligamentum patellae there

was a slight swelling, which was painful. Her general health was tolerable; she rested well at night, except when disturbed by the pain, which was always worse then. She was put to rest, and had a blister applied to the knee, and afterwards a poultice.

The report of to-day is, that the pain in the joint is less; she has rested better these last two nights, and the swelling upon the ligamentum patellae is diminished. There is some slight crepitus still on moving the patella upon the condyles of the femur.

Whether there be any peculiarity in the form of the inflammation which gives rise, in the one case, to an increase of the synovial secretion, and to a deficiency of it in the other, it may be difficult to say. The same membrane is affected in both instances; there appears from the sufferings of the patients to be inflammatory action going on in both, and both are to be regulated on the same principles. This case has been for so short a period under our notice, that we are hardly able yet to ascertain what will be the ultimate result; but I have no doubt, from experience, having seen many such cases, that it will proceed just as favourably to a cure as the one of which I last spoke.

Other Affections of the Knee-joint.—I have brought these different and somewhat opposite cases forward, to enable you the better to comprehend the points of diagnosis which I have described; and I shall now proceed to the description of two other forms of affection of the knee, which are more rare, and perhaps more difficult to treat.

Besides the structures I have mentioned as contributing to the formation of the joints,—the ligaments, the synovial membrane, and the fibrous tissue,—we have the osseous extremities, which are tipped or covered with cartilages, the cartilages being lined with the synovial membrane. Now the ends of the bones, especially the cylindrical bones, which contribute so greatly to the support of the body, are enlarged. If the extremities of the femur, for instance, were not of greater diameter than that of the rest of the bone, they would be constantly liable to displacement, but Providence, wise in all its works, has, in the formation of the joints, increased the diameter of the ends of these bones; their bodies are of great compactness, and sufficient, under ordinary circumstances, to resist injury, whilst the extremities are exceedingly light, formed of what is called "cancellated structure;" that is, small laminae of bone, intersecting each other, and forming cells, which are lined with membrane, and which probably afford the secretion that we find in the cells of the cancellated structure. This part of the bone also is liable to inflammatory action, which may affect the power of the articulations, and may, indeed, eventually

lead to as serious results as happen from any disease attacking the articulating surfaces themselves.

CASE 3.—*Inflammation of the Osseous Structure of the Tibial portion of the Knee-joint.*—The first is the case of Thomas Lynch, aged 21, living near the Tower, by occupation a footman, and of steady habits. He was admitted into No. 8, Abraham's Ward, on the 27th of August last. He states that about a month previous to his admission, after taking much exercise, he experienced a dull aching pain of the right knee, which increased towards evening, and disturbed his rest greatly. Exercise of the joint increased his sufferings. Two small blisters were applied to the knee, but without affording much benefit. Upon his admission he complained of pain on the inner side of the right knee, particularly at night. At the lower part of the joint, the inner side of the head of the tibia was found to be much enlarged; and upon his placing the foot on the ground, and resting his body on the limb, the pain was increased. He had rheumatic pains in different parts of the body, and his general health was impaired. To procure rest and regulate the secretions, I ordered that he should take a grain of the sub-muriate of mercury, with half a grain of opium, and a blister was to be applied to the knee. By these means he rested, and the pain was somewhat relieved. In the beginning of October, the first blister having healed, a second was ordered, and, the secretions being regular, he was ordered to take the tonic mixture,—the *mistura potassæ hydriodatis*. This is a tonic mixture which I frequently give, not only in such affections as these, but in others, and with great advantage. It contains a sixteenth part of a grain of iodine, four grains of the hydriodate of potass, and a small quantity of syrup of poppies, with a little distilled water, to each dose. The mixture is made of half a grain of iodine, half a drachm of the hydriodate of potass, half an ounce of the syrup of poppies, and half a pint of distilled water; and the patient takes an eighth of this mixture for a dose.

Oct. 16. He had now no pain on motion. The affected limb was rather smaller than the other, for a reason which you will recollect I explained to you at the last lecture,—namely, that where there is disease, and the muscles are not kept in exercise, they lose their contractile power, and become flabby. He now slept well at night; and I ordered him to rub in, over the affected part, night and morning, the *unguentum potassæ hydriodatis*,—an ointment made with a drachm of the potassæ hydriodatis to an ounce of lard.

21. Much the same; joint rather diminished in size.

27. Pain gone; can walk without any in-

convenience. The joint remains a little enlarged, and he was presented well.

CASE 4.—*Inflammation of the Osseous Structure of the Femoral Portion of the Knee-joint.*—The next case is one of inflammation of the cellular structure of the condyles of the right femur. Mary Sullivan, aged 32, residing in Bermondsey, a married woman, of scrofulous diathesis, was admitted into No. 10, Lydia's Ward, on the 19th of November. She states that about seven months ago she received a blow on the right knee, from a fall, which produced considerable pain, but no swelling. The pain continued more or less severe until about four months since, when the joint began to swell, and the pain to increase. She then applied at a dispensary, and was cupped and repeatedly blistered, which, to a certain degree, relieved the pain, but the swelling still continued to increase. In a short time afterwards the limb became very large, and the pain returned with considerable severity. From a continuance of blistering, and the internal use of the sulphate of quinine, the symptoms again subsided, and she discontinued her attendance at the dispensary. About two months ago, the joint, still remaining swelled, became yet more enlarged and sometimes painful, although, until about a fortnight since, she did not experience much inconvenience, with the exception of stiffness of the joint, and pain upon continued motion. At this period she unfortunately struck the knee again, when the pain returned with violence, and has continued violent ever since. At the period of her admission, she complained of a dull aching pain over the whole of the joint, which was particularly severe at night. The motions of the joint, which are very limited, increase the pain, which is more particularly referred to the inner side of the knee—to the situation of the internal lateral ligament, pressure over which aggravates the pain. The condyles of the femur are greatly enlarged, and the patella appears to be sunk down and impacted between them. The general health was good, the appetite was good, and all the secretions were natural. Her general powers, however, are very much below par. She was ordered to have the house-medicine, and the same form of tonic as that which the last patient took,—the *mistura potassæ hydriodatis*; but instead of mixing it with water, as a vehicle, she was to take it in the decoction of *sarsaparilla*. She was likewise directed to have a blister applied over the surface of the knee.

21. She states that she is better. She says that the pain is less, though still severe at night. The tenderness on the inner part of the joint is less. There is still some pain complained of on grasping the femur above the condyles.

Remarks on the Case.—These are re-

the rare affections; they are, however, more frequent, perhaps, as affecting the articular extremities of the bones which assist in the formation of the knee, than in the articular extremities of any others. Still, I have seen the same disease affecting the elbow joint, and the lower extremity of the tibia, the ulna, and the radius. It appears principally to arise in persons of scrofulous habit.

Diagnosis and Pathology.—From the histories of the cases, you must see that there might be difficulty in discriminating between the disease of the cellular structure of the extremities of the bones, and that of the synovial membrane. There is a dull aching pain, which is increased at night, indicating an affection of the fibrous structure; but on examining the joint you easily ascertain the seat of the disease. You find, probably, that the patient, as in the instances before us, complains somewhat of pain, aggravated upon pressure over one of the lateral ligaments. The reason is obvious. The articular extremity of the bone cannot be enlarged without separating in some degree the attachments of the lateral ligament, and thus putting the ligament upon a stretch which may induce a slight degree of inflammation. But the very figure of the joint will strike you as peculiar, and guide you to the *rationale* of the disease. When the patient is the subject of disease of the synovial membrane, with deficient secretion, he cannot have the joint moved without pain, because the synovia that naturally exists between the opposite surfaces of the bones is wanting, and they grate against each other, producing excessive suffering. Now in the instances of enlargement of the articular extremity of the bone, I have known patients only complain of difficulty of motion, or of pain, when the limb was moved, from what they themselves called “a deficiency of the joint oil,” meaning synovia; but in examining the joint I have found the patella move freely on the condyloid surfaces of the femur, proving that the synovia was not deficient. How is the difficulty of motion of the joint, then, to be accounted for? Why in this way, from the articular surfaces having become altered, in consequence of enlargement, and the deformity thus produced. This is beautifully seen in the case of Mary Sullivan. The disease in her case affected the condyles of the femur; the extremity of the tibia remained as before, but the condyles were enlarged, the patella having sunk down between them, and there become impacted; so that even if she were to recover from the disease, I do not think that she would ever again have the proper motions of the joint. Is it then, from somewhat negative symptoms, or from accurate examination, and a comparison of the sizes of the joints, and of the extremities of the bones, that you have to form a perfect diagnosis.

You thus have all the symptoms explained. Sometimes, when disease of this structure has proceeded for a time, you have the periosteum of the bone becoming inflamed, and in consequence of its being expanded over the whole of the osseous substance, the suffering is extreme when it is pressed upon, just as you have pain in what is called “hydrothalamia,” affecting the sclerotic coat of the eye. When that texture is pressed upon, it becomes inflamed, and is extremely painful. Of course the pain is less, in some degree, where the inflammation of the cancellated structure is slow: the only symptom of the disease then, is difficulty of motion. Where the texture is so delicate as the lining of the cancellated structure necessarily is, and when the inflammation which attacks it is slow, the disease is hardly evinced; but when the affection comes on rapidly, you then find, from the enlargement of the bone, and the implication of the membranes connected with it, that the character of the disease is much more decided, and can at once say that it is an affection of the fibrous tissue.

Prognosis.—What is the prognosis? In an instance where the disease has been of slow origin, and of slow progress, it is not likely that the patient will suffer eventually, if proper care be taken, any further than from the irregularity of the joint, and difficulty of motion. Where once enlargement of osseous structure has taken place, you cannot diminish that extent of surface again by any treatment short of operative proceedings. In the first case the patient recovered under the treatment adopted. The size of the joint somewhat diminished, and he was able to walk. Why was this? The head of the tibia was affected; there was a deposit taking place in the osseous structure, the outer shell of the bone gave way, and the periosteum became affected and thickened. You can get the thickening of the fibrous texture of the periosteum reduced, but you cannot get rid of the thickening of the bone; it will remain so during life. In the other case, where there has been much more severity of disease, we shall have much more difficulty of cure. That patient has a scrofulous habit, and weak general powers, which are all favourable to the progress of the local affection. If she can only bear up under the confinement of the hospital, and the atmosphere which she will have to inhale here, I have no doubt that we shall be able to arrest the disease, and to send her forth with the use of the limb; but supposing the atmosphere, and the confinement of the house, do not agree with her, and her general health suffers, it will be prudent to discharge her, in order that she may have the benefit of better air, as detaining her here may cause her to have the more severe form of the disease.

What, gentlemen, will be the progress of

the disease if we do not arrest it? I presume, from the history, that there is a deposition of that curdy sort of matter, which, in scrofulous persons, we see deposited in instances of enlarged glands of the neck, filling, in great measure, the cancellated structure of the bone. If we could cut through the condyles of the femur, and expose the cells, we should probably see some of them broken down, and filled with this substance. But if the disease goes on still further, you will have less of this curdy matter, and in its place a fluid generated, consisting of that serous or indifferent sort of pus which we know to be the result of scrofulous inflammation. When this pus is formed, it will begin to make its escape by ulceration; the cellular structure will be broken down, the denser compact shell of the bone will gradually give way, the cartilages will ulcerate, and we shall have sinuses formed, from the interior of the bone, through which the discharge will take place. Very likely, however, before all this occurs in an hospital, the general health gives way, and we are obliged, with a view to save life, to get rid of the disease by amputation.

Treatment.—The object, however, is to avoid the resort to amputation; and I have, therefore, with a view to preserve the general health in such cases, given such medicine as is calculated to lessen the peculiar disposition to the disease which is termed "scrofulous diathesis." Iodine has a remarkable effect in this respect; and I have combined it with sarsaparilla, which is often necessary. We have also employed the milder forms of counter-irritation; but if we find that a decided improvement does not take place under blistering, we resort immediately, as I shall do in this case, to the more powerful means of moxa, or issues, of which I spoke in my last lecture.

These cases are well worth watching. Instances of the kind are not often seen, but when once seen, and well examined, I do not think you would make a mistake between them and any other affection of the joint. Without knowing such cases, and being aware of them when they exist, you might mistake them for an affection of the synovial membrane, or of the fibrous tissue, and be led to give a prognosis which you could not afterwards verify, and which would be calculated to bring discredit upon you.

In all these cases the utmost you can do is to arrest the inflammation, and put the parts into a healthy condition. You cannot produce an alteration again in the figure or diameter of the bone, which will restore its integrity, and render the joint as fit for the purpose of motion as it previously was. A lameness must always ensue where such an affection has taken place, and has given rise to enlargement of the bone.

Other cases we have under treatment, but I shall not to-day describe them. There

are several cases in which ulceration of the cartilages and destruction of the ligaments have occurred. One or two of these, now under treatment, and they will contribute to form subjects of consideration at our next meeting.

CASE,

PRESUMED TO BE ONE OF

MECHANICAL OBSTRUCTION

TO THE

PASSAGE OF THE BLOOD IN THE ARTERIES.

To the Editor of THE LANCET.

SIR,—The following case (a part of which I read at the *London Medical Society* in February last) I think you will consider worthy of insertion in your valuable Journal. I am, Sir, your obedient servant,

EDWARDS CRISP.

Walworth Road, Dec. 21, 1835.

CASE.—Jan. 31, 1835. I was requested to visit Mary C., *ætat* 22, of healthy parents, residing at Camberwell. She had cholera in March 1831, and says that "her mouth was slightly affected by mercury, but she speedily recovered." I attended her two years since, during a severe attack of pneumonia, after which she had occasional cough, &c. &c. sometime. She has been at service for ten or twelve years, and generally, during that period, was able to follow her employment, but she was occasionally prevented from doing so by headache and hysteria. For the last three or four days she has complained of pain in the legs and arms, with rigors, followed by heat of skin, &c. This morning there is pain in the epigastric region, rather increased on pressure. Pulse small, 90; tongue white, tip red; bowels confined. The menses have appeared regularly, but the discharge has been small in quantity.

R. *Mag. Sulph.* ʒi; *Liq. Ant. Tart.* ʒss; *Aqua* ʒvss. Ft. mist. cujus sumt. ʒ 4tis horis.

R. *Piul. Hydrarg.*, *Ext. Colocynth. C.*, aa. gr. v. Ft. pilule duæ, h. s. s.

Feb. 1. Less pain in the region of the stomach; the thighs and legs very painful; no redness or swelling, but the pain increased on pressure; pulse small and frequent; no sleep; bowels well relieved; motions offensive.

R. *Vini Colchici*, *Liq. Ant. Tart.* aa. ʒss; *Mist. Camph.*, *Aqua* ʒvss. Ft. mist. cujus sumt. ʒ 4tis horis.

R. *Puls. Ipecac. C.*, aa. gr. i. s. s.

2. Much the same as yesterday; slept 100 or three hours; continued of great pain in the legs and thighs; no pain in the epigastric region; tongue red at the tip, with white base; pulse small, 80. The lower extremities ordered to be fomented with a hot decoction of poppy heads, and the following was prescribed:—

R. *Hyd. Sub.*, *Pulv. Antimonialis*, *Pulv. Colchici*, aa. gr. vi. M. et divide in pulv. vi, quorum sumt. unum 4ta quaque hora.

3. Called this morning at one o'clock, and found her suffering from violent pain in the region of the stomach, increased on pressure; frequent vomiting (the first since her illness); no pain in the lower extremities; pulse very small; has fainted two or three times. Opened a vein in the arm, and with much difficulty obtained about ʒvi of blood, after which she expressed herself to be somewhat relieved.

Applicetur *Emplastrum Luteum* regioni epigastricæ, et *Emplastrum Sinapi* pedibus.

R. *Hauft. Suleæ Carb.* et *Acet. Tart.* 4tis horis in actis effervescentiæ.

Eight p.m. Pain less; pulse more expanded; blood capped and buffed.

4. Has very little pain in the region of the stomach, but the legs and thighs are again excessively painful; no heat or redness, and the pain appears to be confined to the integuments; bowels relieved. Cont. medicina.

R. *Ext. Papav.*, *Pulv. Rhei*, aa. gr. v; ft. pilula duæ, h. s. s.

5. Fainted once in the night; no sleep; hands and arms cold, with a tingling sensation in the fingers, succeeded by acute pain in the integuments of the arms; pain absent in the legs and thighs, and very slight on pressure in the epigastric region; tongue furred, tip and edges red; bowels open; no pulsation at either of the wrists; the heart and carotids pulsating with great violence.

Rept. medicina efferves., et sumt. *Pulv. Opii* gr. i hora somni.

8. Has remained much in the same state since the last report; very little sleep; pain in the arms and legs excruciating, but seldom occurring in both at the same time; slight tenderness in the epigastrium; no vomiting; sounds of the heart rather louder than natural; respiratory murmur distinct in both lungs. The menses appeared on the 5th Feb. and ceased to-day. Says she "observed no change in the symptoms during their continuance." Pulsation absent at both wrists since the 5th. Has continued the effervescing draughts, with a grain of opium and ipecacuanha morning and evening.

R. *Ammon. Carb.* ʒss; *Tinct. Opii* gtts. xx; *Mist. Camph.* ʒvi; ft. mist. cujus sumt. ʒ 4tis horis.

R. *Pulv. Ipecac.* C. gr. x, h. s. s.

9. Took the medicine only once, as it produced vomiting; pulsation ceases about an inch below each clavicle; the dorsal arteries of the feet pulsating forcibly, 90; the heart and carotids beating with less violence than yesterday.

R. *Hauft. Efferves.* 4tis horis, et *Liq. Opii Sed.* gtts. xxv, h. s.

10. Symptoms the same as yesterday; no sleep for the last five or six days. Cont. *haust. efferves.*, et sumt. *haust. Opii* h. s.

Feb. 11. Passed a restless night. Did not retain the opiate draught upon the stomach. The integuments of the right arm extremely painful. Met Dr. Whiting in consultation, who examined the arteries with great care, and found the pain much increased when pressure was made over the arteries of the upper extremities, particularly the right. Dr. W. ordered eight leeches to be applied below the right clavicle; a warm spirit lotion to the arm, with the following;—

R. *Hyd. Sub.* gr. j; *Acet. Tart.* gr. ʒ; ft. pilula 3tia quaque hora sumenda.

R. *Vini Colchici* gtts. x; *Mag. Sulph.* ʒj; *Aqua* ʒx; ft. *haust. ter die sumendus.*

12. No sleep; pain in the right arm diminished; has been very faint since the leeches were applied; bowels moved twelve or fourteen times; motions fluid, yellow, and offensive. On pressing the spinous processes of the upper dorsal vertebrae, she complains of pain, but not more so than when the skin of the back is touched. Says her feet are cold and numb, and she has asked the attendants if the toes are not contracted. On examining the feet I found them quite warm. Rept. medicina, et adde, *Pulv. Ipecac.* C. gr. ii, singulis pilulis.

R. *Liq. Opii Sed.* gtts. xxv, h. s.

13. Slept four hours after taking the draught. Can move the arms without difficulty, but has still slight pain when pressure is made in the course of the arteries. The left foot and leg are extremely painful. On pinching the anterior part of the leg she is not sensible of pain, but complains of uneasiness when the back part is pressed. No pulsation in the dorsal artery of the foot, and rather indistinct in the popliteal; heat of the limb below the natural temperature; the carotids pulsating feebly, and on placing the finger upon them a thrilling sensation is communicated; "bruit de soufflet" observed for the first time over the region of the heart. Cont. medicina, et sumt. *Liq. Opii Sed.* gtts. xxx, h. s.

14. Believe I can distinguish a slight vibratory motion at intervals, in the left radial artery. The patient sleeps for five or six

hours; the right arm is again very painful; the gums are affected by the mercury. She has expressed a great desire for porter. Hitherto her diet has been farinaceous, with beef-tea and broth occasionally.

R. *Ammon. Carb.* ʒi; *Soda Carb.* ʒi; *Tinct. Aural.* ʒii; *Aqua* ʒvi; ft. mist. cujus sumt. ʒ in succo limonis 6tis horis.

Rept. haust. *Opii* hora somni.

15. Symptoms nearly the same as yesterday; no bellows sound over the heart; has taken ʒ of a pint of porter; ordered one pint daily. Cont. medicina.

16. Pain in the left foot and leg so severe that she is frequently screaming; no pulsation in the arteries of the upper extremities, nor in the left popliteal; tongue red and moist; skin often covered with perspiration. The porter to be continued.

R. *Haustr. Sulph. Quinina* gr. ii 4tis horis. Rept. haust. *Opii* h. s. Appl. *Emplast. Belladonnae* cruri.

17. Foot and leg more painful since the plaster was applied: no pulsation in the left popliteal, but very distinct in the femoral; pain much increased when pressure is made in the course of the arteries; slight pulsation in the left brachial and radial arteries (beat synchronous with the heart). Dr. Whiting saw her again this afternoon, and recommended twelve leeches to be applied to the left groin; the foot to be fomented with hot spirits and water, and a large blister to be applied to the lower part of the abdomen. Dr. W. thought that by pursuing this plan of counter-irritation we might prevent the spreading of the disease to the larger arteries. The *Belladonna* plaster to be removed.

R. *Ammon. Carb.* gr. iii; *Quinina Sulph.* gr. i; *Syrup. Simp.* ʒss; *Aqua* ʒx; R. ft. haust. ter quotidie sumendus.

R. *Liq. Opii Sed.* gttss. xxv, h. s. s.

18. Pulsation absent in both upper extremities, and ceases about three inches below Poupart's ligament in the left thigh; slept for a few minutes at intervals during the night; pain excessive; the foot and fore part of the leg of a purplish colour; the cutaneous veins distended with dark blood; the tips of the toes cold, and the foot rather below the natural standard; perspiration profuse over the upper part of the body; has been very faint since the leeches were applied; continues the porter; hot fomentations to the foot. Rept. haust. *Quininae* haust. *Opii* hora somni.

19. Foot purple and cold; pain increased; perspiration abundant in the night. Cont. medicina.

20. The foot is not swollen; temp. 84 F.; perspiration profuse; no sleep. Cont. medicina.

21. Pain more severe; slept three or four

hours; temperature of the left foot 80 F., right foot and arm 92. Cont. medicina.

22. During the last two or three days she has complained of having pain in the right popliteal space; yesterday she felt pain and tenderness in the calf of the leg, and, at about eight p.m., a numbness in the foot, succeeded by intense pain, which has continued. On pressing along the course of the femoral artery, the pain is much aggravated; no pain when pressure is made on the outer and back part of the thigh; has also pain when the left femoral artery is pressed, but not so severe as it was on the 17th. No pulsation in any of the arteries of the extremities. The toes and sole of the left foot black; temperature 84; right foot 90. Ordered a blister to the outer part of the right thigh, and eight leeches to the foot.

R. *Pule. Opii* gr. ʒ; ft. pilula ter die sumenda. Rept. haust. *Liq. Opii Sed.* h. s.

23. Slept five or six hours; pain excruciating in both feet, fore part of the left, black; the instep and ankle red; temp. of the former 80; latter 91; feeble pulsation in the left radial and brachial arteries. Rept. *Pilul. Opii* et haust. *Opii* h. s.

24. Slept four or five hours, pain not so violent as yesterday; left foot much in the same state, temperature of the toes 60; ankle 68; right foot 81. Rept. medicina.

25. Pain less; several phlyctenae on the left ankle; pulsation absent in all the extremities. Rept. med.

26. Symptoms the same as yesterday. Rept. med.

27. Feet very painful, especially the left, which looks rather better than on the 23rd; temp. of the sole 70; instep 83.

R. *Haustr. Quinina* 6tis horis.

R. *Haustr. Liq. Opii Sed.* gttss. xl, h. s.

March 6. Since the last report the pain has been excessive; very little sleep; night perspirations; has complained occasionally of pain in the region of the heart; bruit de soufflet very distinctly heard; suffered yesterday (for the first time since her illness) with pain in the right side of the head, which subsided after a few hours. Bowels have acted regularly; motions healthy. The fore part of the left foot in a state of sphacelus, with a red line of demarcation extending obliquely across. Has continued the opium and quinine daily. Ordered yeast poultices to the foot. Cont. medicina.

8. The little and great toes of the right foot black and painful. Rept. med.

16. Removed the phalanges of the two outer toes of the left foot, since which operation she has had less pain; no pulsation in the left arm for the last four days; has taken port wine and quinine daily, with the opium and quinine. Rept. med.

22. Pulsation absent in the extremities since the 17th; bruise the soufflet over the region of the heart; tongue moist and moist; secretions and excretions healthy. No extension of the gangrene on either of the feet. Rept. med.

28. Pulsation absent in the arteries of the limbs, but was perceptible in the left arm, from the 23rd to the 27th. Rept. med.

April 7. Pulsation ceases at about two inches below Poupart's ligament on both sides, and can be felt only at about half an inch below each clavicle; granulations abundant; since the 26th, has been able to take a mutton-chop daily, with port-wine and porter. Rept. med.

Oct. 1. Her health has gradually improved; the appetite is good; the tongue clean; secretions and excretions healthy. The menses appeared in June, and have continued monthly. During the last two months she has complained of giddiness and occasional pain in the head, with dimness of sight coming on towards evening, but she says that "her health is nearly as good as it was previous to this attack." The pain in the foot has been so intense, that for a considerable time she took six grains of opium daily. Notwithstanding this, the bowels acted regularly. She continued the quinine, with the compound iron mixture, until the 20th of June, since which time she has taken no medicine. The bellows-sound is sometimes heard over the region of the heart; feeble pulsation generally in the left brachial and radial arteries for the last three months; absent in the right arm since February. She says that "this is not so strong as the other, but that she is able to use her needle nearly all the day." Pulsation ceases at about two inches below Poupart's ligament in the left femoral artery; in the right it can be felt as low as the triceps. Has lost the first phalanx of the great and little toe of the right foot; all the phalanges, and three of the metacarpal bones of the left; the two remaining are partly exposed. A portion of the os calcis has exfoliated on each side; the foot is much inverted; the integuments are puffy, and painful on pressure. Is not able to keep the foot down for more than two or three minutes at a time, the pain being excessive, and the skin assuming a leaden hue; is very anxious to have the leg removed: the right foot and leg are generally cold.

5. With the concurrence and assistance of my friends Messrs. Bristowe, Bryant, Hughes, and Beane, I performed the circular operation, below the knee. On slackening the tourniquet, I found that there was very little bleeding from the large arteries. The smaller vessels, however, bled profusely, and it was necessary to use plus or ten of them; but little blood was lost, and she bore the opera-

tion remarkably well. Gave her 35 drops of laudanum. Examined the leg with great care. Slit up all the large arteries, but could find no trace of disease in them; they appeared to be smaller than natural. The veins and nerves also were healthy.

Nine p.m. Complains of great pain in the stump; pulse (left radial) quick; skin hot; thirst, &c.

R. *Mist. Efferves.* 4tis horis.

6. Slept two hours; pain less; a little oozing of blood from the wound. Cont. medicina.

7. Symptoms the same as yesterday. Rept. med.

30. Has gone on well, with the exception of a little sloughing on the tibial side of the wound. The part, however, soon put on a healthy appearance, and is now nearly healed. The catamenia appeared on the 9th.

Dec. 21. A portion of the stump, of about the size of half a crown, not healed; the granulations pale, with sero-purulent discharge. Her health has improved since the last report, and she is able to get from one room to another with the assistance of crutches. The right foot is generally cold; pulsation the same as before the operation. Two gentlemen saw her on the 19th, and thought they could distinguish feeble pulsation in the right brachial artery. I have not myself been able to detect it. The bellows-sound is often heard in the heart and large arteries.

Remarks.—The foregoing case, both in a physiological and pathological point of view, will, I think, be considered to be one of great interest. Opinions will, of course, vary as to the exact nature of the disease, but I imagine it will be generally admitted that there is mechanical obstruction to the passage of the blood, and that the train of symptoms described could not depend upon functional disturbance of the arteries. When I first mentioned the case at the *London Medical Society*, I suggested the probability of a metastasis of the integumental disease (which appeared somewhat of a rheumatic character) to the coats of the arteries, producing conglomeration of the blood, and, probably, a deposit of lymph. This opinion is strengthened by the fact of the frequency of translations in rheumatic disease to the heart and pericardium. The case appears to me to confirm, in some measure, the correctness of Magendie's views with regard to the non-muscularity of the arteries. The result of the amputation proved that blood circulated through the larger vessels, but not in sufficient quantity to call their elasticity into play, and hence no pulsation was produced. I invariably found, when the carotids were greatly expanded, that the heart was beating violently, and that its

pulsations were synchronous with the artery. I also observed that when pulsation was absent in the left radial, the heart was acting feebly. The functions of the brain were scarcely disturbed, although the blood was sent through its vessels with great force. The profuse perspirations, confined principally to the head and trunk, evidently reduced the volume of the circulating fluid, and, after a time, allowed the vessels to assume their natural caliber.

CASE OF COXALGIA,

WITH

LUXATION OF THE FEMUR, ANCHYLOSIS,
PERFORATION OF THE ACETABULUM
BY CARIES,

AND

FATAL PERITONITIS.

By WILLIAM TAGERT, Esq., Surgeon to
Mercer's Hospital, Dublin.

THE subject of the following case, John Tamor, a sailor, was admitted into *Mercer's Hospital*, in November 1834, where he remained until his death, comprising a period of ten months. As the principal points of interest were disclosed by the examination of the body after death, I shall curtail the history and symptoms of the case during the protracted residence of the patient in the hospital. He was admitted with a tumour in the upper and outer part of the thigh, at about the region of the tensor vaginæ femoris. The exact nature of this swelling could not be clearly ascertained at the time by an external examination, nor was it deemed prudent to explore it by puncture. The hip-joint and spinal column were carefully examined by the gentleman under whose care he then was, without his being able to detect any evidence of disease in either. There was no alteration in the length of the limb, or in the form of the nates; the swelling gave him little uneasiness, and soon subsided by rest and suitable treatment. Shortly after admission he was attacked with violent pain, and acute inflammation, of the hip-joint and upper part of the thigh, which, notwithstanding a strict observance of the recumbent position, and the frequent application of leeches, with other antiphlogistic treatment, terminated in a large abscess, which pointed in the inferior part of the groin. This was cautiously opened by puncture, which gave exit to a considerable discharge of pus. However, this was soon succeeded by a fresh collection. In the mean time the pain in the hip joint was urgent in the extreme. About seven or eight weeks after admis-

sion it was ascertained, at the morning visit, that the limb was shortened, with considerable immobility of the foot, too plainly indicating that luxation had taken place. From this period there was a succession of abscesses near the joint, terminating in fistulous openings. The constitution, as may be supposed, sympathized with the severity of the local disease, and wasting discharges, extreme emaciation, total loss of appetite, profuse night-sweats, with the other accompaniments of rapid hectic, brought the patient to the verge of dissolution. The integuments in the neighbourhood of the sacrum, and at the lower part of the back, were sloughing, from pressure, but this distressing complication was completely relieved by the use of Doctor Arnott's hydrostatic bed. His constitution was supported with wine, porter, and nutritious diet, and by a perseverance in these means he slowly rallied. The discharges from the fistulous openings, gradually lessening, at length almost ceased; the head of the bone became firmly ankylosed in its new position, and the recovery of the patient was so far advanced, that he was able, with the assistance of crutches, to move about the ward, and occasionally, in the garden, at the rear of the hospital. About seven or eight days previous to his death, he complained of a deep-seated pain in the right iliac fossa. Pressure in that region increased his sufferings very much. The pain extended from this point over the entire abdomen, which became swollen, and exquisitely tender to the touch. The man had constant thirst, and incessant vomiting, which could not be controlled. His drinks were rejected, apparently without muscular effort, immediately after being swallowed. The countenance was sharp and anxious, and the pulse weak and rapid, with extreme prostration of strength. These symptoms terminated fatally on the 20th of September.

Autopsy.—The body was, generally, extremely emaciated. The abdomen was tumid, and on opening that cavity, there was found considerable effusion of serum, with flakes of coagulable lymph. The peritoneum presented the usual marks of inflammation, being in many parts coated with lymph, and its capillaries being minutely injected. The liver was in a state of hypertrophy, but it was not altered in structure; there was sero-purulent effusion in the cavity of the pelvis.

On making an examination of the hip, the head of the femur could be felt in its new situation, not admitting of motion in any direction. The limb was somewhat shortened, with complete inversion of the foot. Before I proceeded to the dissection of the joint, I wished to ascertain the route of the different sinuses, by making them open with a bistoury, and passing them to their

terminations. There was a small opening in the upper and outer part of the groin, just beneath Poupert's ligament. On passing into it a small flexible bougie, I was surprised to find its course to extend upwards, towards the abdominal cavity. On tracing it I found a long narrow fistulous tract, which traversed the iliac and psoas muscles, and terminated at the spine, where the two last dorsal vertebrae were found extensively carious. Another fistulous orifice was situated at the outer part of the hip. In laying this open upon a grooved director, it brought me, by a tortuous route, to the acetabulum, the bottom of which was completely destroyed by caries, and allowed the director to pass freely through it into the cavity of the pelvis, thus establishing a communication between this cavity and the surface of the body. There was, likewise, a fistulous opening at the outer part of the thigh, lower than its centre, with one or two other fistulous openings of minor consideration, in the neighbourhood of the joint. The glutæus maximus and medius muscles, were much wasted, and intimately adherent to each other, and to the parts beneath, which were altogether changed in structure, being converted into a tough fibrous mass, difficult to be cut with the knife. The glutæus minimus, pyriformis, gemini, and obturator internus, with the sciatic nerve, were all so blended together, by the effects of repeated attacks of inflammation, and deposition of this new fibrous substance, that it was impossible to distinguish one structure from another. I could not perceive any thing resembling a capsular ligament. The posterior border of the acetabulum was destroyed by ulceration, and the anterior surface of the head of the femur was found immovably fixed, and resting on the ilium, close behind it, approaching the schiatic notch. The great trochanter looked forward, and somewhat outward, in front of the original articulating cavity. Where the head of the bone rested, a new socket was formed, rather by a depression of bony matter around it, than from absorption of the part of the os innominatum where the head was fixed. The acetabulum was much occupied by a ligamentous structure, but its bottom was destroyed by caries, and, as has been previously observed, led by a fistulous opening into the cavity of the pelvis. The head of the bone did not seem to have suffered much from caries, as it appeared to be undiminished in size. A preparation exhibiting the diseased parts is preserved in the Museum of the Hospital

Remarks.—I am aware that Mr. Brodie, in his admirable work on diseases of the joints, has given instances of caries of the acetabulum, opening into the pelvis. In the dissection of this case, he says, "At the bot-

tom of the acetabulum there was an ulcerated opening, just large enough to admit a common probe, communicating with an abscess within the pelvis." In another case, he remarks, "there was an ulcerated opening at the bottom of the acetabulum, communicating with the inside of the pelvis." He likewise refers to two preparations belonging to Sir Astley Cooper, in which the abscess burst into the rectum. Other authors have recorded similar facts, but I am not aware of any instance where peritonitis was the consequence, except in the case I have just related. I have no doubt but that the peritonitis was the result of the carious acetabulum communicating with the pelvis, and I am strengthened in this opinion from the circumstance of the man's complaining of deep-seated pain in the right iliac region, for two days previous to its being fully established. I do not see much difficulty in arriving at this conclusion, where a fistulous tract exists, one orifice of which opens on the outer surface of the hip, and the other upon the inner wall of the pelvis. May not inflammation have been transmitted by continuity to the structures immediately within the pelvis, and from thence to the peritoneum, the secretion from the fistulous passage acting as a foreign body? When luxation occurs as a consequence of this disease, I believe that the head of the bone is almost always found to have passed *upwards* and *outwards* on the dorsum of the ilium. In one instance only has Mr. Brodie observed a luxation *forwards*, "the head of the bone resting on the pubis." In the case which I have related, the head of the bone does not occupy either of these positions, but is thrown *backwards* behind the acetabulum, and in a very slight degree upwards. Observing the extreme tenuity of the bottom of the acetabulum, a person unacquainted with the resources of nature in resisting the effects of disease, would feel surprised that matter did not more frequently make its way inwards in such cases. Velpeau, in his "Surgical Anatomy," has the following judicious observation upon this point:—He says, "the bottom of the acetabulum is so thin, that it would be very easy to perforate it in disarticulating the thigh, and thus plunge the point of the knife into the pelvis. On the other hand, caries or necrosis may traverse it also, as too frequently happens in severe coxalgia, and if the pus do not then escape into the cavity of the pelvis, it is because the soft parts which line it become thickened and indurated, in proportion as the disease advances, and thus oppose to it a more or less solid barrier, but which, nevertheless, is not insurmountable."

Dublin, Dec. 22, 1836.

TRIAL OF MEDICAL MAGNETISM

AT WESTMINSTER.

To the Editor of THE LANCET.

SIR,—As I perceive with regret that my name has been alluded to in connection with mineral magnetism in your report of what took place at the *Westminster Medical Society*, I must, in justice to myself and the public, crave a corner in your valuable journal, to state a few facts connected with this subject. The virtues ascribed to mineral magnets by one party and denied by another, are, you are well aware, by no means new.

Dr. Schmidt asserts that his peculiar method of charging or increasing the power of the magnets is new, at least in this country, and his method of producing a north pole by a north, and a south by a south, while Drs. Faraday and Ritchie assert, on the contrary, that there is nothing new in the method; and as to the poles producing any other than these opposites, it is a complete fallacy, and both these gentlemen deny in the most positive manner the curative powers; and further, that no physiological effect can be produced by them,—that on the living body they are totally inert.

But to enable Dr. Schmidt to prove the physiological as well as the curative powers of his magnets, the *Westminster Eye Hospital* patients were offered him for his selection, and it seems that from eight cases of amaurosis, Dr. S. selected four of the most favourable for the magnets. At the end of two weeks, on Saturday the 12th inst., to the surprise of many, and myself among the number, Mr. Hale Thompson reported to the *Westminster Medical Society* "that the mineral magnets had produced a certain physiological effect, both at the Eye Hospital and the *Westminster Hospital*, namely lachrymation and great mobility of the iris." As I felt very much interested in the subject, it occurred to me that instead of magnetic influence, the physiological effects mentioned by Mr. H. Thompson might be produced by the cold of the magnet. I immediately had a bar of wrought-iron, of nearly the same weight as the magnet, made in the form of a horse-shoe, and on Wednesday the 16th inst. in the *Westminster Eye Hospital*, Dr. Schmidt himself tried the effect of my bar of wrought-iron on Mr. H. T. and on several other medical gentlemen present, when precisely the same physiological effects were produced on all. What curative effects may be reported, of course I have not the means of judging. In the above investigation I have had nothing for my object but an inquiry after truth, no person, no not even Dr. S. himself, will rejoice more than I shall do, if the magnets can be brought to our aid, if only in the

alleviation of human suffering. By the insertion of the above you will very much oblige me. I remain, Sir, your very obedient servant,

ROBERT DAVIDSON.

Parliament-street, Dec. 29, 1835.

SCHEME

FOR REGULATING

PAROCHIAL MEDICAL ATTENDANCE.

To the Editor of THE LANCET.

UNCONNECTED as I am with any party in the profession, I have no hesitation in expressing my sincere pleasure on perceiving a modification of your views as to the origin of the abuses now perpetrated in the rural districts, under the name of "Medical Relief."

In the excellent observations contained in the leading articles of the three last Numbers of *THE LANCET*, you place the question in its true light. The blame attaches to the entire administration of the Poor-Law, and the Somerset-House gentlemen, as the head of that administration, are the principal, though by no means the only offenders; nor is there any probability of redress until "the conduct of the Poor-Law Commissioners and their assistants be brought before the consideration of the Executive Government and Parliament."

But of what use will complaints be, unless we are provided with a remedy? In accordance, therefore, with your general request to the profession to furnish suggestions, and as an answer to your direct question, "what is the scheme that medical practitioners would recommend?" permit me to propose a plan, which, as far as it has any merit, will recommend itself to your attention, and to that of your numerous readers; and, even should it be altogether undesirable, will, I hope, be the means of calling forth more suitable and unobjectionable schemes of amendment. I propose, therefore, three principal measures.

I. That there be a certain and uniform remuneration for parish medical attendance.

II. That parochial surgeons be fully authorized, in every case, to decide upon the necessity of their assistance to sick paupers.

III. That the rate-payers of each parish appoint the medical attendant of their poor.

1st. As to Remuneration.—The principle of appointment by "tender," and test of the qualification of medical candidates, is so manifestly wrong, so fraught with evil, so unfair to settled practitioners, and so pre-

ductive of transactions disgraceful to the character of the profession, that its abolition would be hailed with satisfaction by every medical man, except those infatuated speculators, whose object is, *at any risk*, to occupy a point *d'appui*, from which to invade the practices of their previously established brethren. Nor is the plan adopted in some other Unions more defensible; viz. a certain remuneration offered, far below the previous expense of medical attendance, without any reason assigned, except that of "economy," and forced upon the medical residents under the threat of introducing one of the students, or half-pay surgeons, whose names are on a list at Somerset House. Both these abuses would be removed by the adoption of a scale of remuneration, calculated upon the real cost of proper medical attendance. But suppose the principle of a fixed scale of remuneration were determined upon, several questions arise as to the *mode and data* of its calculation, and as to the *persons* by whom it should be calculated.

2nd. *As to the mode*. It must be either estimated by the total number of paupers in each parish—or it must be by an average payment for each case of illness. The former appears most generally acceptable to medical men, and is proposed in an able pamphlet by Mr. Yeatman, of Frome; it adopted, however, the *distance* of parishes from the medical officer, as well as the *superficial extent* of large parishes, must be provided for in addition to his plan.

But I doubt the propriety of this mode, for the following reasons:—1st, the difficulty of the calculation is much greater. Indeed, I know not exactly how a scale, containing a variation in the number of paupers, a variation in the distance of parishes, and a variation in their superficial extent, could be compiled; and without either of these three items it would be imperfect as a guide to a fair and reasonable remuneration for the trouble and expense bestowed. 2ndly, the total number of *paupers* is not by any means always proportional to the number of *sick*. 3rdly, disputes might often arise as to who are strictly paupers; since the regular paupers of the country are rapidly diminishing, as a distinctive class. And 4thly, it is probable that the administration of the Poor-law will reduce the number of *paupers* much faster than the number of *patients* who must be attended by the parish surgeon.

None of these difficulties present themselves with the payment per case; and it has the advantage of being recommended by the Poor-law Commissioners. Each separate payment must, however, depend on the *total number* of patients likely to be attended, and on the *distance* of every patient from the medical officer. These two conditions would comprise the three variations of the preceding mode of calculation, and

might be easily embodied in a scale similar to one proposed by Mr. Rumsay, of Chesham, to the Wycombe Board of Guardians. The objection to a payment per case is, that it is a temptation for the relieving officer to withhold slight cases from treatment. This objection is so valid, that it would be absolutely necessary to deprive the relieving officer of this power, before the plan were adopted. Then it would be unobjectionable. But more of this under my next proposition.

As to the persons by whom the calculation should be made, most certainly it should not be entrusted to the Poor-law Commissioners, nor to our own body, exclusively; but I think it might be fairly settled by the two parties in conjunction, that is, the country practitioners might appoint a certain number of deputies (the fewer the better for the execution of the business), who should have power to treat with the Commissioners on the subject; or, what would be preferable, the Government might appoint some disinterested persons, whose attention may have been previously directed to the expense of medical attendance for the poor, to decide on the amount of remuneration.

By whomsoever made, the scale should be in force only for two or three years, in order that unavoidable defects may be rectified, and unforeseen variations in prices may be periodically adjusted.

3rdly. *As to the power of "ordering" medical attendance for the sick paupers*. This must no longer remain in the hands of the relieving officers. It is utterly unjustifiable that these men, who in many instances are ignorant and unfeeling, necessarily absent from home during the greater part of their time, and anxious to curry favour with their employers by a rigid parsimony,—I say it is monstrous, that to these persons should be intrusted the delicate, important, and prompt decision, as to whether the applicant requires medical assistance. Almost all the coroners' inquests that have been held on neglected paupers since the introduction of the new Poor-law, have implicated the relieving officer.

It appears to me, therefore, that the medical officer must be the first referee in every case, nor should the sick pauper have to do with any other authority until medical advice has been obtained. Some check would, of course, be required on the surgeon, to prevent the lavish distribution of relief to those whose circumstances do not entitle them to parochial assistance, and this might be arranged by a subsequent appeal to the relieving officers, or by the Board of Guardians declaring that the relief afforded is by way of loan, to be recovered according to the provisions of the Act on that head.

4thly. *That the rate-payers of each parish should elect their medical officer*. This point is one, which is rather likely to be passed

over as unimportant; to me it appears far otherwise; for even supposing that the first and second propositions should be agreed to, the Boards of Guardians would still have it in their power to inflict much personal injustice and general injury, by the appointment of unfit and unacceptable persons to fill the responsible situation of parochial medical attendant.

Indeed, in proportion as the office might be made a more desirable one, so would a system of jobbing and favouritism prevail more generally in these appointments. In a union of twenty or thirty parishes, the guardians cannot be expected to know the merits of each medical candidate, nor to judge impartially of the wants of each locality; the friends of the influential members of the board would, therefore, frequently be chosen in preference to the independent practitioners, who might possess no other recommendation than the confidence and good will of the parish in which they reside, — a recommendation which *now* often tells more against than for a candidate. Above all, the vile system of *medical districts* might still continue in force, for although the guardians would be unable to economize by it as they do at present, yet the mere wantonness of power, and the absurd fancy of simplifying their arrangements, might lead them to appoint three or four medical officers, where ten or twelve ought to be employed. These apprehensions are not merely speculative, but arise from a close observance of the working of present measures.

Not only, therefore, as a preventive to these evils, but as due to the parishioners and to the medical profession, let each parish elect its own surgeon. The *merits* of the candidate will surely then be the only question with the electors, and as no increase of expenditure would follow their exercise of the right of suffrage, it is but in accordance with the liberal spirit of the age that it should be extended to them.

The contested election between Mr. Cosgreave and Mr. Dunn, for the parochial surgerency of St. Clement Danes, is a striking fact in support of my proposition. If four or five guardians had been left to settle that matter, it is just as probable that Mr. Dunn would have succeeded as Mr. Cosgreave, although the latter was obviously entitled to hold the office, from "the humanity, skill, and industry, with which he had for nine years discharged his duties in that parish." Your remarks on that election were as just as its termination was fortunate.

Once more, therefore, I submit that, to put an end to the vexatious and unsatisfactory mode of appointment now in vogue, to increase the respectability of the office, and to prevent future chicanery and patronage, the rights of the rate-payers should be restored, and the parochial surgeon elected

by the votes of the majority. This election need not interfere with the supervision which the Boards of Guardians, as the executive power of parishes, must continue to exercise over the conduct of all parochial functionaries.

I have now, Sir, laid before you the heads of my plan,—there are many details which I refrain from troubling you with. Trusting to your liberality for the insertion of my remarks, I remain, at present preferring to be known only as, your obedient servant,

RURICOLA.

Dec. 21st, 1835.

PLAN

FOR REGULATING

MEDICAL ATTENDANCE ON THE SICK POOR.

"Da dextram miserum."—VIRG. *Æn. lib. 6, l. 370.*

To the Editor of THE LANCET.

SIR.—You have, in advocating the cause of more than a million of the human race, when suffering from disease, very properly reminded the profession, that the time is fast approaching when its members should agree on some "almost unobjectionable plan," for the removal of the gross defects of the present system of medico-parochial relief. You truly intimate, that all concur in the necessity of a change in the system, and that the only question is, what are the principles on which the alterations should be made, and how they should be carried into effect? And, finally, you have most judiciously observed, that it will be of little use again to direct the attention of the House of Commons to the subject, unless the profession be provided with a remedy for the evils, already so fully made known, and so generally acknowledged.

It is now nineteen years since my sentiments on the medical care of paupers were first recorded in the *Medical and Physical Journal* of London. In the year following a plan was suggested by me for legislation, which was published by Longman and Co. The scale of medical pay, as contained therein, was not, however, sufficiently graduated, and was much too high to be likely to receive the sanction of Parliament, from which quarter alone any fair and final settlement of the question was to be expected. From 1818 to 1834, I watched, even more carefully than before, the working of the contract system. Meanwhile, the plan alluded to was distributed among Members of both Houses of Parliament, the clergy, and the medical profession; and, in spite of expense and discouragement, a new

and improved edition was circulated, like the former, first inserting a copy of it in *THE LANCET* for April, 1831, with a graduated scale, which cost me no little labour to construct. My plan, which embraces one uniform system in the appointment and salaries of parish surgeons, consists mainly,

1st. Of a graduated scale of remuneration per head, and per hundred, of paupers, falling in price, in proportion to numbers, but below which rate of pay, no surgeon should be permitted, by law, to contract.

2nd. It recognises the principle of a comparatively *minute* division of medical labour, secured by appointing surgeons to parishes, or districts, in *rotation* (after two years' residence and practice), and limiting them to the care of two thousand paupers, annually, where medical men can be obtained in the immediate neighbourhood of the respective parishes or districts.

3rd. The contracts recommended, are to include casual paupers and interlopers, the treatment of compound and simple fractures and dislocations, and those attended under a suspended order of removal; no bill for extras being allowed, except for midwifery and trusses.

4th. It is also recommended that no pauper should receive medical relief, without an order from the proper authorities, unless in very urgent cases.

Permit me, Sir, to refer my professional brethren to No. 400, page 151, et seq. of your periodical, for the details of the plan alluded to, and to express a fervent hope that they will support it, unless they can produce one more worthy of their confidence, and of my humble but zealous assistance.

Many valued correspondents approve of the plan under consideration, while some propose, in addition to the salaries, so much per mile for journeys beyond the first mile. This item of pay, I apprehend, would be opposed in Parliament, because it would unsettle the amount of salaries, and open the door to real or supposed imposition. Surgeons would be suspected of performing more journeys than necessary. My experience, however, and close attention to the whole of this most important subject, induce me to recommend that the expense of drugs be defrayed by parishes or unions, instead of by medical contractors, the amount of which would be in augmentation of professional remuneration under my scale; and this probably might meet the views of those who think it too low, while it would remove all suspicion of paupers not being duly supplied with medicine. The medicine to be furnished by select vestries or guardians, with the advice of the parish, district, or union vestry, and to be placed in a room fitted up for the purpose by order of guardians or vestries. This room to be in a convenient situation, in which the surgeons or their assistants should dispense the medicines, at

stated hours, except in cases of emergency, when it should be done, as heretofore, at their own houses and at their own expense.

The union of parishes has increased the number of medical monopolies, and, in the same proportion, has rendered it impossible to discharge the medical duties, while many districts of unions are much too extensive for the medical superintendence of individual surgeons. The former miserably low rate of pay has been reduced in the districts and unions, and advertising for tenders is, in effect, farming out the care of the sick to the lowest bidder. In short, the well-known evils have been very recently multiplied and aggravated.

In defending the appointment of young surgeons, immediately from the schools of medicine, the Poor-law Commissioners speak of the superiority of their education, as compared with that of their elder brethren affirming it to be equivalent to the experience of the latter. But this singular argument, applied only to one of the departments of medicine — midwifery — will lead, if acted upon, to inhumanity and death; since in difficult cases of childbirth (about which alone, parochial, district, or union surgeons are consulted by midwives), nothing short of experience will enable them to overcome the difficulties of the case.

Another error of great magnitude has been committed by the commissioners, in advising guardians to pay surgeons so much per patient, instead of per pauper, per annum. The relieving officer, knowing nothing of the insidious approaches of disease, will, in numerous instances, refuse orders for medical relief, except in obviously severe and protracted cases of illness and accident. And it is frightful to contemplate as to what may become of pauper sick, after the half-crown fees, per patient, shall amount to the former salaries, for attendance on whom the district and union surgeons are not to be paid one farthing.

To amend the law regarding the medical care of paupers, will be as great a benefit to parishes as to the sick and hurt poor, since the latter, being more skilfully treated, will sooner be removed from the list of those receiving parish support. How many cripples, blind persons, and individuals unable to work, have remained through life a burden to themselves and parishes, in consequence of medical neglect, and the bad management of fractures, dislocations, and diseases of the eye, and of those numerous chronic forms of disease, the victims of which might have been restored to health and profitable labour, if duly supplied with medicine and advice in the earlier stage of disease! How many parents have died, who might have been saved under a better system of medical relief, and whose families have been thrown on their parishes for support! To say nothing of the impulses of humanity, a

change of system may be truly advocated in Parliament, in accordance with economy. No pecuniary saving will result from leaving one portion of the pauper population to the care of medical contractors, at 2s. 6d. per patient, while another portion is to depend only on the eleemosynary aid of medical practitioners, notwithstanding the fact that their services in this way are beyond all praise,—services performed like those of the illustrious Boerhaave, who declared the poor to be his best patients, because God was their paymaster.

I remain, Sir, your obedient servant,
J. C. YEATMAN.

Frome, Somerset. Dec. 28th, 1835.

THE LANCET.

London, Saturday, January 2, 1836.

It may suit the feelings and objects of certain mischievous imps who play their tricks in the temple of bigotry in the Strand, to allege that the professors, the Council, and the proprietors of the *London University*, or, as it is hereafter to be called, *University College*, have been endeavouring to obtain for that institution an all but exclusive nomination in the charter, which it has been proposed by the CHANCELLOR of the EXCHEQUER to frame for the establishment of a metropolitan university. The allegation is a gross, unqualified calumny, so far as the professors and the Council are concerned. What may have been done by the proprietors, generally, or by individual members of that body, we know not; but it is notorious that neither the members of the Council, nor the professors, have ever made any application to the Crown, or to the executive Government, for any, the smallest exclusive privilege, either for their own benefit, or for the advantage of the institution to which they are attached. When they endeavoured to obtain the power to confer degrees, neither in their petition, nor in the arguments of their advocates before the Privy Council, was a single fact stated, or an argument advanced, which had a tend-

ency to throw into the shade the merits of their contemporaries, or the claims of other bodies to legislative honours and protection. This position was assumed with perfect justice, and was maintained with boldness and consistency. The senate claimed for their pupils those honours which were awarded at other universities, and where higher, or more efficient appliances for the acquisition of such honours, cannot exist. There was not the slightest pretension to exclusiveness, in any one of their demands; but having felt that they were fully capable of rendering their pupils competent to undergo an efficient examination in literature, in the arts, and in the sciences, they claimed the privilege of awarding university honours, under the sanction of a charter, because, and only because, there was no public examining body in the metropolis to which the candidates for university distinctions could be referred.

No sooner, therefore, was the proposal made, that an university should exist in the metropolis, under the sanction of a charter granted by the Crown, than did the professors of the University willingly say "content" to the principle of a scheme which would recognise before the Examiners of the Metropolitan University, the perfect equality of all the candidates for literary and scientific honours and distinctions. In taking this course the professors judged rightly, both as regards their own reputation and the interests of the public. They have honestly denounced monopoly, and they courageously rest their hopes of success for their pupils, on the abilities which they (the professors) are capable of displaying in the discharge of their duties. Besides, it must be recollected, that the act of applying to the Examiners who are to be appointed by the Crown will be a voluntary one. There will be no compulsion whatever in the case. The student may, or he may not, become a candidate for the degree, and it would be madness to suppose that a curriculum will be framed which shall have

the effect of determining the person at which a man must choose to become a candidate for university distinctions. This consideration, as well as a multitude of others, clearly points to the necessity of establishing the University in this metropolis upon the broadest basis—upon the most liberal and well-understood principles. It would be far better to be without any university in London than to create a new monopoly, though a new monopoly would be created beyond any doubt, question, or cavil, if the pupils of particular institutions are to be selected for examination, to the exclusion of all other applicants. What is it that the Government designs to honour? Is it learning? Is it a knowledge of science? If it be so, let the fact be declared, and let the example accord with the precept. If, on the other hand, the honour is to be obtained because there had been weight of metal in the pocket, instead of solidity of information in the head, why let an accordant declaration be honestly and boldly made. We have always in this country laboured under the misfortune, in our national transactions, of beginning at the wrong end. In short, money has been made a passport to every office, to every distinction,—except, indeed, in those few cases where money, after talent has been left to work its way up to a certain point, has been used as the instrument of temptation, for moulding down the possessors of talent into pliant tools, to be used by the hand of power. It really would appear, from what is passing before us, that there is to be a free trade in every thing except in the means of obtaining knowledge and literary distinction; but is a principle which is odious in the ordinary and gross occupations of trade, to be continued for the purpose of fettering, restraining, and binding down, the faculties of the human mind? Without adverting to the general principles which have hitherto existed in England, let our attention for a moment be directed to the charter of the City of London, and advert to the control which can be exercised,

through its possession, over the proceedings of Smithfield market. Suppose that in that charter the names of two or three counties in England had originally been introduced as those of favoured places, and that no cattle were allowed to be sold in that market, unless they had been bred in the counties particularized, the charter requiring that “certificates” in evidence of that fact should be produced by the sellers, to the full satisfaction of the Company of Butchers, that no deception was attempted, that no fraud on the terms of the charter was about to be practised. Not one whit more glaring is such an absurdity, and, probably, not half so pernicious in operation would be the possession of this exclusive privilege on the part of the favoured counties, as would be the exclusive privileges of two or three institutions in the metropolitan universities, if any were secured to them by the proposed royal charter. The public would naturally say, “How monstrous a thing is this! Here we are deprived of excellent beef, because no oxen can be sold in Smithfield, unless it can be satisfactorily certified that they were bred in Oxfordshire, Lincolnshire, or Devonshire! And, more monstrous still, the graziers in those counties, knowing that no other cattle than theirs can be received into the market, have become quite indifferent about the breeding, and comparatively careless in feeding their stock, placing full reliance on the force and value of that exclusive and monstrous privilege which has existed so long in their favour. Why should there exist any other law upon the subject, than one which gives to every proprietor the opportunity of making the most of his stock? There are the oxen. They exhibit their own qualities. The slaughterers who purchase them are fully capable, from experience, of testing the nature and value of those qualities. Why, therefore, should legal restraints of any kind exist, relative to the breeding, the buying, and the selling of cattle? Common justice demands that

"the occupiers of the soil in every county
"in the kingdom, should be placed on a
"perfectly equal footing, and the interests
"of the public require that the principle of
"competition should be allowed to operate
"in the market, with a free and perfectly
"unrestrained scope." It is perfectly clear
that the man who breeds the best cattle
wants no protection from the law, and it
will, we hope, be willingly acknowledged that
the farmer who breeds the worst cattle,
ought not to enjoy a monopoly in the arena
of sale.

What has the exclusive system accomplished at Oxford and at Cambridge? What has the same system accomplished in the hands of the knavish medical corporations of London? What has the certificate exaction wrought for science, or for the public? The gentlemen who are engaged in framing the new charter should furnish the reply to these questions. Degrees have been granted, diplomas have been conferred, licenses have been sold, all under the operation of the certificate system. And what do we discover as the result? Why, that men of acknowledged talent, who enjoy University titles and collegiate distinctions, constitute the *exceptions* from the general mass, and that the great body of titled graduates, possess no claims to public confidence, either in science or in literature. We have had enough, then, of the old system. Away with it, and for ever. Let the Government establish in its place an institution which shall be ruled by the principles of justice and common sense, and let public utility be the mark towards which every arrangement and every formula shall be directed.

There are some gentlemen of known ability, and acknowledged liberality of sentiment, who profess to be of opinion that an examination, however comprehensive it may be, or however well it may be conducted, cannot be rendered a sufficiently satisfactory test of the quantity and quality of the information which is possessed by a candidate who is under examination for a license

or a degree. These persons, we say, are necessarily disqualified from occupying the office of University Examiners. They have too much doubt of their own powers, to allow them to analyse with correctness the powers of others. If men of sense had not put forth such a statement, we should unhesitatingly have termed it "nonsense," and have received it as the mere vapouring of undoubted imbecility. If, however, we were to admit to these parties, which, of course, we should only do for the sake of argument, that the examination is not an adequate test of the abilities of the examinee, would the production even of half a thousand certificates of attendance upon lectures, add to the number of the mental acquirements of the candidate? Would the possession of such documents increase his capabilities? Obviously not. But the display of a bundle of "certificates,"—which, in reality, are only so many receipts for money paid,—might produce a most pernicious impression on the minds of the Examiners, as it is next to impossible to believe that those gentlemen would consider that the candidate had been defrauded out of so many pounds sterling, through the operation of the curriculum of the University.

What just, what legitimate, what philosophical, or what rational connection is there between the *payment of money, and that state of mind which renders a person capable of showing that he is entitled to distinction in the ranks of his scientific and literary countrymen?* Let this be shown, and we will hereafter remain silent on the subject. In the meantime we shall confide in the enlightened views of the Government, and shall continue to think that the Professors of University College have done themselves lasting honour by disclaiming for the celebrated institution to which they belong, every privilege which is not in common with even the least of their contemporaries.

The circumstances attending the appointment, by the Irish Government, of a successor to the late Mr. McDOWEL in the *Richmond Hospital*, illustrate, in a very striking manner, the absurdity of the present mode of disposing of medical offices; and also place in a striking light the opinion which is now held respecting it by the public and the profession.

Formerly, when an appointment of this kind was at the disposal of the Government, the matter excited but little attention. Under vicious rulers, professional worth is compelled to forego its claims, and leave promotion to be quietly settled between corrupt patronage and its dependants. This has been more particularly the mode of advancement in Ireland, where a "chosen people," few in number, and resident in the midst of a great population, monopolized every place of advantage or emolument within the gift of the Crown. No one, indeed, ever thought of disturbing the settled rules of nomination to vacant situations. The predestined possessor of place was generally foreknown, and his induction permitted without any attempt at competition, and almost without complaint. The Tory administration of affairs in Ireland bred their own agents, and none but the produce of the old stud were suffered to enter the field.

But at last the case is altered. The extension of civil rights in Ireland, by widening the grounds of eligibility, and inspiring hopes of preferment, has enlarged the sphere of rivalry for official situations, and raised a host of candidates to urge their claims with all the sturdiness of new-born liberty, and the watchfulness naturally excited by long-endured exclusion. The principles of equity in the distribution of patronage, which characterize the administration of Lord MULGRAVE, gave an additional impulse to the rivalry of political parties in Ireland, and on the present occasion, in a state of unprecedented activity. To such extent, indeed, were applications made to

the LORD LIEUTENANT for the vacant place in the *Richmond Hospital*, and with such persevering solicitations, that his Excellency would, we believe, have cheerfully yielded up his power in exchange for an exemption from the vexatious requests to which his office had subjected him. The instant it was known that the life of Mr. McDOWEL was despaired of, the siege commenced; and before the undertaker had decently interred the remains of the deceased, the Castle was surrounded by applicants for the empty chair. The liberals, of course, were early in the field, and calculated, each, on the congeniality of his principles with those of the executive. Every doctor or surgeon who had an M.P. of the popular party for his friend, at once called the senatorial influence into action, and sought to reduce the Irish Secretary into obedience, by promises or threats of popular power. One candidate, indeed, is said to have stowed *six* Members of Parliament into his barouch, and made an overwhelming "avatar" on Lord MORPETH with this exhibition of representative authority. The sudden and assiduous display of social and domestic virtues which was made on the occasion was most amusing. Fathers and fathers-in-law, brothers and brothers-in-law, uncles and nephews, all forgot their differences in a moment, and struggled to obtain for some dear relative the prize in the lottery of professional life. Every art, in short, which ingenuity could suggest, was put in requisition; and a very pleasant farce, called "The Rival Doctors," might, with very little trouble, be elaborated from the contents of the Secretary's bureau relative to this contest.

As a refuge from the responsibility attaching to the discharge of a duty which every Government, thinking correctly and meaning honestly, must consider itself incompetent to discharge rightly, the Irish Executive appointed three commissioners, Mr. CRAMPTON, Mr. CARMICHAEL, and Mr. COLLES, to dispose of the situation. But in

the working of this plan, it is said, the Government was disappointed. As might have been expected, the surgeons differed in consultation, each having his own private interests to advance. The result, however, is, that Mr. ADAMS, one of the surgeons of *Jervis-street Hospital*, and Mr. M'DONNELL have been appointed; Mr. CARMICHAEL, the friend of these parties, having himself resigned to make way for one of them. The gentlemen selected are certainly well-informed men, and in every respect equal to the discharge of their new duties. Some displeasure, certainly, has been manifested against the Government, for the appointment of Mr. ADAMS, in consequence of his political views, which are said to be altogether *Tory*; but this is a ground of complaint which is hardly to be named in connection with a system of appointment which in its very essence outrages common sense and reason. Under the present mode of arrangement, in fact, general satisfaction cannot be given; nor have any parties a right to complain, so long as they acquiesce in the existing system of elections, and pursue the same obnoxious means of preferment as their successful rivals. What ought the feelings of fathers, or friends, or uncles, Members of Parliament, have to do with appointments to hospitals? Until this wretched means of promotion is abolished, and the "concoirs" established in its place, expressions of complaint and dissatisfaction will continually attend all hospital elections. Had those who now repine with disappointment met in conference, and, like the surgeons of the hospitals of Paris, on a recent occasion, protested against promotion by the vile machinery of private interest, they would have deserved the sympathy of the public, and the support of the press; but so long as they consent to be the agents of a pernicious and absurd system, they cannot justly look for either. Now their complaints are only mocked. Their own corrupt inclinations, and the incompetency of even the best Government to decide with justice in

such cases, are by chance, are now ~~ab-~~
~~roughly~~ understood. From such reasons as these is it that we feel strong apprehensions of the successful working of that part of the Metropolitan University scheme, which gives to the Crown the nomination of the members of the "Executive." In organizing a new project, and putting it into operation, in the first instance, the appointment of the officers by Government, may not only be an excusable, but even a necessary, proceeding. If, however, it is intended that this method should be *continued*, without resort to the "concoirs," in filling the minor offices, and thus gradually make it imperative on the Government to ratify the election of those men only who, by such an ordeal, prove themselves to be the best qualified among the candidates, why then, indeed, the Government plan could not be too severely reprobated. But, as we have already intimated, we shall await the publication of a draft of the proposed charter, ere we say more on this important subject.

We have selected for insertion in this week's LANCET, from several letters which we have received on the same subject, two able communications, (pp. 540, 542,) both containing schemes for regulating the medical contracts in parishes. Mr. YEATMAN has on several occasions discussed this subject with very great ability, and in the letter signed "RURICOLA" there is evidence that the writer has devoted the energies of a thoughtful mind to the question which is now occupying so large a share of the attention of the medical public. A careful consideration of the contents of these documents, must lead to the opinion that no useful or final settlement of a "plan" can take place, unless the parts of which it is composed, receive the most deliberate investigation in the presence of an assembly of medical practitioners. ~~Is it necessary~~
 that a large body should meet for the purpose. Ten or a dozen gentlemen, who pos-

the capabilities and experience of Mr. YEATMAN, the author of the letter signed "RURICOLA," would be as well qualified to execute the task, as would be a committee of one hundred. But when the importance of the ulterior object of influencing members of Parliament is estimated, the more numerous the attendance, the more favourable will be the chances of carrying out the contest to a successful result. Should it be determined, by surgeons who are practising in the country, to hold a meeting in the metropolis, we would suggest the propriety of postponing it until within a few days after the meeting of Parliament, at which time the members of both Houses of the Legislature might be visited, with the best results, by their medical friends. We hope that experienced practitioners will not be sparing in their remarks on the plans which are this week proposed by our correspondents. The subject, altogether, demands a very patient investigation.

AN advertisement was published on the cover of *THE LANCET* of December 19, in which it was announced that a Dispensary had been opened in Aldersgate-street for the treatment of poor persons who may be afflicted with fistulous and other diseases of the rectum. The founder and surgeon of this institution is Mr. SALMON. On first hearing of the proposal to institute such a Dispensary, we felt inclined to question the propriety of adding another to the number of our, so called, "medical charities;" but on giving the subject a more attentive consideration, we are inclined to believe that this Dispensary, if it be conducted on the principles which have been set forth in the prospectus, will be productive of some important advantages, not only to the public but to the profession. The practice of this institution, as is to be observed, is to be opened, without payment of a fee, to all medical practitioners. Thus the profession will now have an opportunity of ascertaining whether

that class of diseases which is to be received for cure at this Dispensary, occurs with such marvellous frequency as has been alleged by some living authors who have written on the subject; or whether, in fact, increased experience, and further opportunities of observation, will not tend to confirm the suspicion which has long been entertained by many eminent surgeons, that this department of surgery has long been made a source of profitable and disgusting quackery.

It has been denied by the hired tool of the Bats that Mr. LISTON was solicited to become a candidate for the chair of surgery, lately vacant in the University of Edinburgh. The statement, however, which was first published in *The Courier*, evening newspaper, remains not only unrefuted, but is fully confirmed by some remarks which have been made in the Town Council at a meeting of that body, and reported in the *Edinburgh Weekly Journal*. On that occasion Con-ventor DICK said, that

"When Mr. Liston was lately in Edinburgh, performing an operation, he (Con-ventor D.) asked Mr. Liston if he would become a candidate, as the patrons were at that time looking out for a fit person to fill the surgical chair; and Mr. Liston then said, that he would not forego his prospects in London for such an appointment. Since that time, however, having had occasion to write Mr. Liston, he again requested to know if he would come forward; in answer to which, in a letter he had received, Mr. Liston stated, that an appointment to any chair in the University, would not induce him to become a candidate."

This declaration of course will set the question at rest in the minds of all persons who have not some knavish or malignant feeling to gratify. "But oh!" somebody may say, "the Council as a body did not offer the chair to Mr. LISTON." Of course it did not. The experienced men of the North are more cautious in their proceedings than to take such a step. Individual members of the Council having ascertained that Mr. LISTON would not leave London, the Council, as a body, reasonably enough, refrained from addressing Mr. LISTON on the subject. This is the whole of the matter.

THE LATE DR. WARREN.

DR. PELHAM WARREN died at his house in Berkshire, in the 57th year of his age, after a lingering and distressing illness, during which he was attended by his old and faithful friend, Mr. Pennington. His death was occasioned by an abscess in the liver, which burst into the colon. He was of the atrabilious temperament, and of a slender physical frame, and had a dark and penetrating eye. He was constantly taking snuff, indulged freely in the juice of the grape, and, like all sensualists, was slovenly in his person. The circumstances, altogether, of his life, in which extreme indolence was a predominant feature, made it not surprising that he should fall a victim to hepatic disease. He was laconic in his discourse and somewhat coarse in his manner, and to many was by no means a pleasing personage. On one occasion a lady was humorously describing to him the characters which a sick but very jocose friend had drawn of several medical men whom she had at different times consulted, among whom was Dr. WARREN himself. Sir HENRY H. she described as having "the manner, flippancy, and flexibility, which would have made him a first-rate valet, or a good lady's maid." Dr. MATON must have been intended, she thought, for "a village school-master," and Mr. BRODIE "for a Wesleyan minister." "And what did she say of me?" asked Dr. WARREN. "I will candidly tell you, said his friend, that she thought you had a great deal of devil in your face."

Dr. PELHAM WARREN was the son of the late Dr. WARREN, the Sir HENRY HUMBUG of his day, a London pure physician, who was considered to be one of the most expert men in the trade, contriving to leave behind him a considerable fortune, as the result of his talents, without adding one item to the treasures of medical science. Alas! his "knowledge of the world," as it is called, enabled him to secure for his son PELHAM an easy and safe path to successful practice as a London doctor. Educated in a school where bigotry had arrived at its acme, and corruption swayed unmolested, young WARREN had every opportunity of deriving the advantages which attend a classical, and what has of late been even more highly appreciated, an Oxford moral education; and between Windmill-street and St. George's Hospital, he found quite enough of physic both to answer the purpose of a pure physician, and to procure for him a cordial welcome as a Fellow within the portals of the College in Pall-Mall East,—one of the most venerable and antiquated institutions in the empire.

Those who acquire in the outset of life an ephemeral station in any profession, seldom rise to great eminence in its ranks,

for they are bereft of that most powerful of all stimuli, industry, which excites to industry, and compels its subjects, as it were, to acquire knowledge. Dr. WARREN's scientific fame, it may therefore be expected, like that of his associates in the College of Physicians, though it was considered quite sufficient to enable him to practise what they considered as the higher department of physic, and such alone as are deemed legitimate objects of attention for a pure physician, were not so comprehensive as to allow him to make any addition to medical science. Indeed, excepting one paper, which was published in the "Transactions of the College of Physicians," and the title of which had, for the fame of the deceased, better be concealed, he never even attempted to make a contribution for the advancement of his profession. Dr. WARREN had that due contempt for anatomy and pathology which becomes those individuals who assume to occupy the "highest grade" in the profession, and during a period of twelve years, in which he officiated as one of the physicians of St. George's Hospital, he used to boast that he had never once been in the dead-house. Indeed, the levity and derision with which this pure physician treated everything like pathological anatomy, will scarcely be credited. Sir BENJAMIN BRODIE, in confirmation of this discreditable fact, narrates, with that satirical simper in which the pure surgeons indulge when speaking of their still purer brethren in Pall-Mall East, the following anecdote: "One day, when WARREN was waiting in the board-room of St. George's Hospital, to know the result of a post-mortem examination that was going on in the dead-room, he got impatient, and while warming his coccygeal region at the fire, addressing himself to a colleague who was near said, 'This d—d morbid anatomy will spoil the practice of physic.'"

As a consulting physician Dr. WARREN was not very highly estimated by the "subordinates" of the profession. Possessed of inordinate self esteem, he was more eager to dictate than to suggest means of treatment. He used, also, to prolong his attendance on patients unnecessarily—at all events contrary to their wish, and thus got for himself the character of rapacity for fees.

The circumstance of Dr. WARREN's never having applied himself seriously to the study of medicine, or any of the sciences immediately connected with it, is to be regretted, as he possessed a rather better order of intellect than the mass of his fellow collegiates. Had his education and habits been different, his mental powers would have been sufficient to raise him to a professional distinction. But once formed the views and opinions of those by whom he was educated, and with whom he associated throughout life, he contented himself, as we

have observed, with very superficial acquirements, and only relying on a knowledge of *Xenophon* and *Tacitus* as authors whom it is no doubt a gentlemanly accomplishment to understand, but whose works form a very undue portion of those volumes which are necessary to be studied by practitioners of medicine. With all these deficiencies of education, however, he was by no means deficient in practical diagnostic tact, and he was sufficiently well acquainted with the routine of his profession to enable him to fulfil its ordinary duties. Dr. BAILLIE used to say of him that he was a "tolerably good guesser." Many collateral advantages combined to introduce him, early in life, to a considerable extent of private practice; and for some time, estimating him by his income, he was considered a first-rate pure physician, though his fees during the last few years, in consequence of his illness, and the great change which has taken place in the fee-trade of consulting physicians generally, diminished considerably. His illness, indeed, so materially interfered with his attention to business of late, that, contrary to the opinion of many, he left behind him but a very indifferent practice for the aspiring generation to succeed to.

With all his peculiarities Dr. WARREN possessed some of the best feelings of human nature, which it is more pleasant to notice than the imperfections of his character. Some mention being lately made of these in a private circle where the death of Dr. WARREN was the subject of conversation, a lady thus interrupted the conversation. "Ah!" said she, "speak not slightly of Dr. WARREN. I knew him well. All my family in him placed the greatest confidence, and I know he had a tender heart. He long and kindly attended my beloved sister, who died of consumption in the South of France, whither she was sent in the hope of saving her valuable life. At his last visit she asked him many questions about the danger of her situation and her hopes of recovery, and after having given her the best answers he could, and left the room, my brother, unknown to him, observed him, standing at the top of the stairs, bathed in tears."

In the capacity of a Fellow Dr. WARREN was considered as the leader of a kind of opposition party in the College of Physicians, that opposition, however, not having for its object any "rational" improvement in its constitution, but being aimed to displace or to clip the wings of the President, who had so long ruled with sovereign sway from the walls of that sanctuary. In the early days Dr. WARREN was a Whig, and Sir HENRY was deemed the *se plus sûr* of ultra-Whigs; and although Dr. WARREN's arbitrary feelings and manner towards the "lower grades" were as

haughtily exercised as were those of Sir HENRY, yet, as he did not possess the *saavifer in modo* of the Baronet, he never had any chance of unseating the courtly President. Dr. WARREN was by no means a blind observer of human nature, and he was quite familiar with the twistings and turnings of the eel-backed President, and was wont to express himself very freely on this subject. An event took place on the death of the late King, which induced him to express his opinion very decidedly on Sir HENRY, and to pursue a course which was regarded by some at the time as of a very manly and straight-forward kind. His Majesty had scarcely "breathed his last," when Sir HENRY hastened from Windsor, in the dead of the night, to Bushey-park, where then resided the DUKE of CLARENCE, to communicate the doleful tidings to the new King. The occasion which so speedily melted the heart of the royal successor was too favorable to be neglected for making some necessary worldly arrangements with WILLIAM the FOURTH, and Sir HENRY's persuasive powers were such, that though the KING, prompted by the best feelings, had declared that he would not change any of the servants of his brother, Sir HENRY convinced his Majesty of the "advantage to the nation" of allowing him alone to form the medical staff of the household, and obtained the royal promise to concur in all his recommendations. As might be expected, Sir HENRY, with his usual excellent discrimination, selected his own personal friends to fill every one of the appointments to which any emolument appertained, judiciously awarding to himself the most lucrative. From the position which Dr. WARREN at this period held in the College, Sir HENRY felt that he could not entirely pass him over in the new arrangements; yet he wished to place him in no situation of distinction. So, without asking Dr. WARREN's leave, or saying one word to him on the subject, he gave in a list, and got it at once officially announced, in which Dr. WARREN appeared with the inferior title of "Physician Extraordinary." According to professional etiquette this was considered both degrading and insulting; so when this appointment was announced to Dr. WARREN, he declined the honour in the most contemptuous manner, emphatically declaring "that he would be damned if he would accept any appointment from HALFORD," at the same time addressing a letter to Sir HERBERT TAYLOR, the King's private secretary, requesting him to cancel the appointment.

On another occasion Dr. WARREN displayed similar feelings of contempt at the conduct of the President. When the ephemeral conversaziones at Pall-Mall East were first got up, every means were adopted to procure a crowded attendance, in order to show the influence and popularity of the

College, and persons of every denomination, from the cabinet minister down to a Treasury-clerk, — from the archbishop to the curate, received invitations. The apothecary "par excellence," the chemist and the druggist, "subordinate" and all, received cordial invitations to become actors in the scene. With a view to make the contrast between the Fellows and the licensed physicians on this occasion the more striking, it was contrived that the cards of invitation should be issued in the name of the President and Fellows, and that the Licentiates should thus be *invited by the Fellows* to attend the meetings of *their own College*. The insult had not the effect of driving away all the licentiates, though it was sufficient to prevent the most respectable amongst them from submitting to the humiliation. This, however, was not enough by way of contrast, and the ingenious President therefore proposed that, to give additional lustre to the "higher grade" in the College, all the Fellows should appear attired in their collegiate robes. To this proposal Dr. WARREN contemptuously objected, observing, "that Sir HENRY, if he chose, might make a mountebank of himself, by wearing his robes, and he did not care if Sir HENRY came to the College with a feather in his —."

SINCE the day on which the Council of the College of Surgeons admitted the *Charing Cross Hospital*, with its sixty beds, into the list of "recognised" hospitals, it has been a gradually increasing object of desire with the managers of the *King's College*, to connect the College with that hospital, the

medical department of the College having wholly failed to obtain "remunerative" classes of students, and at last, we understand, the urgency of the case has led to the commencement of negotiations with the medical officers of the hospital, but as yet the parties in the College have not got beyond an assent to the demand of Messrs. PERTIGREW and HOWSHIP (who carry their heads exceedingly high on the occasion), that Mr. MAYO and Dr. F. HAWKINS shall resign their professorships in favour of Mr. PERTIGREW and Dr. SHEARMAN. It is most probable, that, on finding themselves out of employment, Messrs. MAYO and HAWKINS will retire to the *Middlesex School*, where, however, matters are in almost as bad a condition as they are in the Strand. Yet, after their late and not yet finished correspondence, it is difficult to imagine how Messrs. MAYO and HAWKINS can act congenially together again in any school.

CORRESPONDENTS.

INSTEAD of publishing any one of several letters which we have received relating to the following subject, we beg to say that a general impression seems to be entertained in the *Medical-Chirurgical Society*, that it is contrary to good taste, good judgment, and the spirit of his office, for the president of the meeting, whoever, for the time being, may occupy the chair, to address the assembly on the subjects under discussion, so many as twelve times in one evening.

We have mislaid the letter on Creosote in the case of vomiting. Can the writer furnish us with a copy of it?

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE VII.

CEREBRAL HEMORRHAGE.

(Concluded.)

GENTLEMEN, we have now studied rapidly the causes of cerebral hemorrhage, and have pointed out the several circumstances which favour the development of this disease, but we have not entered into the minute history of each cause, a general view of the most important questions connected with diseases of the nervous system being the chief object of this course. Having thus considered the causes, we come to a consideration of

The Symptoms which indicate the actual Effusion of Blood into the substance of the Brain.

These symptoms are such as to permit their division into several series. In some cases they are merely the prodrome of the hemorrhage which is subsequently to take place. The patient is affected with headache, or giddiness, with numbness of the limbs, a disagreeable creeping sensation, &c., in a word, with all the signs we have already pointed out as indicating a greater or less degree of cerebral congestion, and these are generally comprised under the expression of "mollimen hemoragiale." Secondly, the premonitory signs are added to may be altogether wanting, the hemorrhage takes place without giving any warning of its approach, and the patient is instantaneously struck down

by a violent effusion into the hemispheres. It is to this form that the term "apoplexy" more peculiarly belongs. A great number of the symptoms of cerebral hemorrhage depend upon the actual effusion of blood; they are the result of the presence of a foreign body in the brain, compressing, or in a certain number of cases actually lacerating, the substance of that organ. Again, other phenomena that we observe, depend not upon the effusion which has taken place, but upon other morbid changes that coincide with it, such as ramollissement &c.; these form a third series. Finally, other symptoms manifest themselves, at a greater or less period after the occurrence of the hemorrhage. Thus we have occasion to see apoplexy complicated by the super-vention of ramollissement, of inflammation, of congestion, forming at several points of the brain, a long time after the first attack, and these circumstances, by troubling the march of the symptoms, by giving rise to various phenomena not connected with effusion, often render the diagnosis and treatment of cerebral hemorrhage a matter of some difficulty. Hence you see how several of the symptoms that accompany effusion of blood in the brain, do not depend on the hemorrhage alone, and can conceive the necessity of distinguishing these secondary phenomena from such as are intimately connected with the original disease.

What is the nature of the symptoms of cerebral hemorrhage? This is the first question we have to examine. They consist in certain troubles in nutrition, relation, and the faculty of reproduction, together with a few anomalous phenomena that we shall have to consider apart; but before entering upon this part of our subject we may ask, can we have cerebral hemorrhage without the manifestation of any symptoms? In the immense majority of cases, the occurrence of effusion of blood into the cerebral substance, is betrayed by symptoms that leave no doubt as to the nature of the accident which has taken place; however, we must, on the other hand, allow the possibility of cerebral hemorrhage taking place without any of the great functions being disturbed. In proof of this I will quote the case published by M. Le NORMAT

in the *Journal Hebdomadaire*, vol. 1, page 435. You will there find the case of a female, thirty years of age, who laboured under what is called the hemorrhagic diathesis, in a most remarkable manner; she had frequent discharges of blood from the mucous membrane of the intestinal canal; from the fauces and mouth; from the uterus; finally, tumours, evidently depending upon effused blood, formed under various points of the cutaneous integument, and the patient sunk under the exhaustion produced by this frequent loss of blood. After death a certain number of apoplectic coagula were found disseminated throughout the brain, yet this patient did not exhibit a single symptom connected with effusion of blood into the nervous centres. I do not know another example of the same kind in the records of medicine; hence, giving it the attention and weight it merits, we must at the same time regard it as an exceptional fact, as a case so extremely rare that it cannot justify the deduction of any principle.

We have distinguished the symptoms of cerebral hemorrhage into three classes, viz those connected with relation, with nutrition, and finally with generation; we shall now take up the disorders manifesting themselves in the life of relation, and these comprehend derangements of the intellectual faculties of sensibility and of motility. 1st for

Lesions of Motility. (Paralysis.)

The most characteristic symptom of cerebral hemorrhage is, beyond all doubt, paralysis: a sudden and permanent lesion of motility indicates effusion of blood into the cerebral hemispheres more surely than any other symptom we know of. Remark, however, that it must present the two characters we have just mentioned; the paralysis must be sudden; it must persist for a greater or less period of time. One alone of the two circumstances is not sufficient to indicate the existence of apoplexy; the loss of motion must have taken place in an abrupt manner. When once established it must continue for a length of time; with these two characters we are justified in pronouncing on the occurrence of hemorrhage of the nervous centres; without these our diagnosis should be given with some caution and doubt. This diminution of muscular contractility exists, with various degrees of intensity, in nearly every case of cerebral hemorrhage, we say nearly every case, for the exceptions, though excessively rare, do sometimes occur; in a few cases no true paralysis has been observed, as for example in the one we have already cited. Another similar case has been published by Dr. SECAZIN, in his thesis on apoplexy, sustained in the year 1827. The subject of this observation died without having presented the least trace of paralysis, and on examining the body after death, a coagulum as large

as a hen's egg was found occupying the posterior part of the right hemisphere, above the ventricle, and extending thence into the posterior portion of the corpus striatum.

These are two very remarkable cases, I believe they are the only two which exist in the records of medicine; note them, therefore, with attention, and reflect on the curious, the incomprehensible circumstances of effusion to a considerable extent having taken place into the substance of the brain, without giving rise to the slightest derangement of the faculty of locomotion.

The paralysis once established, does it continue throughout the course of the disease with an equal degree of intensity? No; in some cases, even when effusion of blood to a great extent has taken place, the loss of motion, at first grave, may go off, and then return again with its former characters. It is difficult to explain these intermissions in the principal symptoms of apoplexy. One would think these are times at which the blood acts with less force upon the brain than at others. However, in most cases the paralysis persists, and only goes off in proportion as the effused blood is absorbed, and the pressure thus removed.

We have next to inquire at what period the paralysis makes its appearance. The loss of muscular action coincides with the instant of hemorrhage; it may suddenly acquire a high degree of intensity, and should a fresh hemorrhage take place, which is not unusual, it may augment. In general, however, it remains equable for some time, and then gradually diminishes; or it may increase until the patient dies, or, as we have already noticed, take on an intermittent character, and present itself with much greater intensity at one period than at another.

We now come to the degree of paralysis: this is an important part of the subject. In some cases we observe only a very slight *engourdissement*, or weakness of the affected member. If it be the hand, the patient is unable to press an object with his accustomed force, although he can take hold of it with precision. The power of motion then remains; we have simply a diminution of the muscular force. In other cases the movement is modified in a still greater degree; the weakness of the limbs is more marked. Finally, in some cases motion is completely destroyed, and the limbs are in a state of perfect paralysis. In a word, the lesion of motility may vary from *engourdissement*, to a slight weakness of the arm or leg, and thence to complete impossibility of muscular contraction. Before this diminution of contractility manifests itself, we may have no other symptoms; it does not present any trouble or pain, it may last up to the very moment of the attack. In other cases, before the occurrence of actual paralysis the limb is weak. The

patient exhibits certain symptoms allied to congestion: the mind more or less modified, or we remark other troubles of motility, such as convulsions, contraction of the limb, &c; however, these latter phenomena announce the coincidence of another lesion, and we shall have to speak of them more fully in a subsequent lecture. The paralysis, then, commences with the effusion of blood into the cerebral substance, and disappears with the removal of it; whenever another order of symptoms sets in, we may presume that some other lesion of the brain, such as congestion, softening, inflammation, &c., have given rise to it.

Paralysis, the consequence of cerebral hemorrhage, variable, as we have just seen, in intensity, presents numerous varieties, according to the seat of the effusion. We shall now examine this point; we shall take up, successively, hemorrhage of the cerebral hemispheres, of the mesocephale (*pons varolii*), of the cerebellum, and, finally, of the spinal marrow, endeavouring, as we go along, to point out how far pathological anatomy can throw light on the great varieties which present themselves; and, first, for

Hemorrhage into the Substance of the Cerebral Hemispheres.—How does this form manifest itself? Hemorrhage of this portion of the cerebro-spinal axis may give rise to either general or partial paralysis; it is general where both sides of the body, either in totality, or in some of their several parts, are deprived of movement. Let us now see under what circumstances we may observe general paralysis. The loss of motion takes place in one of the three following cases:—1st. When the hemorrhage is double—i. e. when it occupies both hemispheres of the brain at the same time; 2nd. We may observe general paralysis, with hemorrhage into only one hemisphere; but the effusion has been very extensive; the blood has lacerated the parietes of the lateral ventricle, and thence made its way into the other cerebral cavities, either through their natural communications, or by laceration of the septum lucidum, and other parts; thirdly, and finally. When the hemorrhage, as in the former case, is confined to one hemisphere, and does not communicate with the ventricles: being, however, sufficiently extensive to destroy a great part of the cerebral mass, and then producing double paralysis, as in the two cases already enumerated.

There then are three causes of general paralysis—viz. double effusion of blood; but passage of the blood from one hemisphere to the other through the lateral ventricles; single effusion without the ventricles, with extensive destruction of the hemisphere. When this general paralysis exists, the four limbs drop like

so many masses of inert matter, without sensation and without motion; sometimes it persists, and the case is then constantly fatal; or, after having characterized the onset of the disease, it may disappear in a certain time, and become converted into hemiplegia. Of this latter circumstance we have witnessed a few examples, and it often arrives in the third case we have distinguished above, where general paralysis exists for the first twenty-four hours, and then terminates in hemiplegia. However, we would here repeat a remark which has been already made, that general paralysis belongs much more frequently to cerebral congestion than it does to hemorrhage, and that in cases where hemiplegia exists, it is 200 to 1 that the loss of motion depends upon an effusion of blood into the nervous pulp.

When the paralysis occupies only one side of the body, we call it

Hemiplegia,

an accident, we again repeat, which, when it arrives suddenly, is the best sign of hemorrhage into the cerebral hemispheres. It then persists a certain time, and is gradually dissipated with the removal of its exciting cause. When it does take place, we generally see both limbs on the same side of the body affected at the same time. However, hemorrhage of the cerebral hemispheres may produce paralysis of only a single limb; sometimes the superior, sometimes the inferior extremity being the one affected. When both limbs together are paralyzed, we generally see the side of the face attacked, at the same time, with loss of motion. The muscles of the cheek, lips, &c., cease to act, and the antagonism necessary for the regularity of the features being lost, whenever the patient talks or laughs the mouth becomes deviated, and the face more or less partakes of the distortion. Gentlemen, it is a law, almost universal in its operation, that hemiplegia (and also paralysis of the face) is seen occupying the side of the body opposite the hemisphere into which effusion has taken place. Authors have endeavoured to explain this remarkable phenomenon, which they attribute to the intercrossing of the pyramids in the medulla oblongata. The pyramidal bodies are, you know, continued through the substance of the mesocephale to the cerebral hemispheres, and hence the fibres of the right hemisphere pass to the left side of the spinal marrow, and vice versa. This appeared a very natural explanation, and was universally adopted by nearly all those who have written on the pathology of the brain. But permit me to lay before you one or two observations, by which, I think, its value is diminished if not altogether destroyed. In several cases where the members are paralyzed, we also remark a loss of motion in the muscles of the face opposite the seat of effusion in the

brain. Now the muscles of the face are supplied by nerves given off *above* the intersection of the pyramids just alluded to, and hence we cannot have recourse to the anatomical fact for the explanation of a phenomenon that occurs at least as regularly, if not so frequently, as the paralysis of the members on the side opposite the effusion; we therefore think we must accept the law already stated, without explaining it in the manner generally adopted.

We now come to other facts that are, as it were, tormenting to us, so much do they differ from those we have left, and, indeed, from all that are considered as forming the type of cases of cerebral hemorrhage. We have, as you remember, laid down a general rule that paralysis is seated on the side opposite the effusion. Facts of this kind present themselves to us by hundreds; but we possess, in the records of our science, twelve published instances, and we know one which is proper to ourselves, being all of them

Cases in which the Loss of Motion occupied the same Side of the Body as the Hemorrhage.

Let us now examine these facts in some detail, requesting your attention to the subject as one of peculiar interest, although the history into which we are compelled to enter may appear a little tedious. We shall enumerate them in the order of their date.

The first case of the kind is ancient. You will find it mentioned in the *Seputchretum* of BONNETUS; however, we shall not insist much on it, because it is not given with sufficient details to render the case an important one; let us therefore pass on to the others.

The second case belongs to FORRESTER, and is found in his observations, liv. 10, chap. 12. Here the case was that of a child two years old, affected with hemiplegia of the right side of the body. After death, a portion of the right cerebral hemisphere was found in a state of ramollissement. The injury here does not in the least alter the state of the question. Softening or effusion, no matter which, it is not the nature of the lesion we seek, but its connection with paralysis on one or the other side of the body. Even at the period when FORRESTER wrote, the attention of pathologists had been turned towards the investigation of the point we speak of. He expressly mentions that he looked for a lesion on the left side of the brain, but found none.

Our third case is given by MORGAGNI; but we must remark from the outset that he relates it on the authority of another, not from his own observation. The patient was a man seventy years of age; attacked suddenly with apoplectic symptoms, and hemiplegia on the right side of the body. After death an effusion of blood was found in both ventricles, and an erosion occupying the

optic thalamus on the right side. This observation is vague and unsatisfactory. We do not know the nature or extent of the erosion alluded to. You see at once that the case does not belong to MORGAGNI himself, but is reported on hearsay. We do not, therefore, consider it of much value, and would rank it in importance with the first we have cited, from BONNETUS.

Our fourth case is an important one in more than one respect; it is reported by an excellent anatomist, M. BRUNSER (the same who has left his name to the follicles of the intestinal canal), in the "Acta Curiosa," decury 3rd. The subject of this case was a female, forty-seven years of age. During a period of four years she had been affected with paralysis of the right side of the body. BRUNSER found a cyst in the right hemisphere of the brain, which showed that an effusion of blood had taken place into that part at a remote period; besides this he discovered a recent clot, the effect of the hemorrhage which had compromised the patient's life. The fact we now mention is an important one, because it belongs to an anatomist of established reputation, one accustomed to researches of pathological anatomy, and capable of appreciating correctly the various morbid changes which present themselves in the dead body. We therefore place it above the cases mentioned by BONNETUS and MORGAGNI, and on a level with the one cited from FORRESTER.

Our fifth and six cases belong to the fasciculus of *Pathological Anatomy*, of the justly celebrated MORGAGNI. In his fifty seventh letter he speaks of an old woman who died with paralysis of the right side of the body. In examining the brain, he found a portion of the right hemisphere in a state of ramollissement. The left side of the brain was examined with care, but no lesion of any kind could be discovered. Again, in his thirteenth letter, he describes the case of another female, twenty-four years of age, cut off by an attack of apoplexy. Half the body on the right side was paralyzed, yet the only morbid appearance in the brain consisted in a clot of blood occupying the posterior part of the corpus striatum on the right side. And this great observer, who was perfectly acquainted with the law of opposite paralysis, not content with his first examination, returned to the body again and again; and, after a careful inspection of all the left portion of the brain, in which he expected to find a lesion, exclaims, on discovering those parts intact, "Mirandum!" Here, then, is a case whose authority we cannot reject. The habits of MORGAGNI as an anatomist and a correct observer beyond all doubt the fidelity of the case described; while the terms in which he expresses himself, show that his conclusion was found in the left side of the brain, it was because no lesion actually existed there.

We now arrive at a more recent date; one of those has been published by M. BELL, in the *Revue Médicale*. The paralysis occupied the left side of the body, and on inspecting the brain, ramollissement was found in the left hemisphere.

You will find our eighth case in the work of M. ROSTAN on *Ramollissement of the Brain*, p. 29. It refers to a woman, eighty-four years of age, who died with an hemiplegia of the right side of the body. Traces of an ancient hemorrhage, together with softening of the cerebral substance, were found in the posterior portion of the right hemisphere.

The next case to which we would allude was observed by M. LEURET, and published by him in the *Journal de Progrès des Sciences Médicales*. The subject of this observation was affected with paralysis and contraction of the right arm. However, after death the lesion was found occupying both hemispheres. On the left side it was very slight, and not discoverable without attention. The right side of the brain was the seat, on the contrary, of a very extensive ramollissement. This case, as you see, cannot have very great weight, from the circumstance of the lesion existing simultaneously at both sides of the brain, but remark that on the side opposite the paralysis it was very insignificant, while on the same side a most extensive destruction of the nervous pulp had taken place.

The tenth case is published in the volume of the *Revue Médicale* for the year 1826. An old cyst was found in the left side of the brain, and the hemiplegia also occupied the left side of the body. However, we must remark that it is an imperfect case. Thus it appears the paralysis was of recent date, though the lesion was evidently ancient. Now, as the author does not tell us whether the patient had presented any paralytic symptoms at a more remote period, we cannot strictly establish a connection between the symptoms and morbid appearances.

The two last cases, completing the twelve, were published by M. BLANDIN in his edition of the *Anatomie Générale* of BICHAT, which came out, I think, in the year 1831. He saw at Bicêtre two old patients who died in a paralytic state. After death the lesion was found occupying the same side of the body as the paralysis. No morbid appearance could be discovered in the other hemisphere. Now no person can doubt the capability of M. BLANDIN, as an anatomist, and we place the fullest confidence in what he has related. Here, then, are two cases, perfectly authentic; we should have no doubt that the lesion existed in the posterior hemisphere.

It is not without some interest to remark that in the two cases recorded, the lesion and injury occupied the posterior lobes of the hemispheres also, and per-

haps this fact of anatomy may give an explanation of the phenomenon now under consideration. If we believe the assertion of some anatomists, the posterior cerebral lobes seem to receive the fibres from that portion of the spinal marrow not engaged in the intersection of the pyramids. It is of the utmost importance, that the description of the pathological lesions of the brain should be given with the greatest minuteness and detail. We would, therefore, engage you, whenever you make observations of disease of the nervous system, and note down the appearances after death, to endeavour to localize the lesion as closely as possible; to measure its actual distance from certain known points, describe every fibre that has been injured, and not neglect a multitude of details, which in any other part of the body, might perhaps appear tedious. It is only in this manner that our knowledge of the functions of a complex organ like the brain can in the end be extended; it is the want of this accurate observation which has so long retarded the progress of the science in the study of nervous disorders.

I mentioned just now, that in addition to the twelve cases contained in authors, I knew of a thirteenth which has not yet been published. This case was communicated to me about two months ago by Mr. CERVILLIER. He saw an individual affected with paralysis, and found, after death, ramollissement or hemorrhage on the same side of the body as the loss of motion. I do not now exactly remember which lesion it was, but you can conceive that the fact reminds the same under either circumstance. What we want to establish is the occurrence of paralysis on the same side as the injury of the brain. I should add, that I have never witnessed a case of the kind myself. In all those which I have had occasion to examine (and they are not few), the loss of motion was on the side of the body opposite the effusion into the brain. From all that has been said, it follows, as a necessary and inevitable consequence, that from certain anatomical conditions which have hitherto escaped discovery, the paralysis may sometimes occupy the same side of the body as the lesion. The facts we have cited, and many of them are irrefragable, prove this beyond any doubt; it is a circumstance worthy of every attention, and you cannot apply yourselves to the elucidation of a more interesting point of the history of cerebral disease, than to this occurrence of hemiplegia at the same side as the effusion.

[As the commencement of the next lecture concludes the foregoing subject (occupying three paragraphs) we here subjoin it. Ed.L.]

I have laid before you an analysis of thirteen cases of cerebral hemorrhage, in which, while the effusion of blood occupied one side of the brain, the limbs were affected

with paralysis, not on the side opposite, nor is almost universally the case, but on the same side with the effusion. I have, however, omitted to mention some which exist in the annals of the science; let us hasten to supply the omission, which I only discovered since our last meeting.

Two cases of hemiplegia, affecting the same side of the body as the lesion, have been published in the *Bulletin Clinique*, by M. DECHAMBRÉ, of *Salpêtrière*. They are accompanied by all the details necessary to give them authenticity, and merit our attention on that account, as well as for the interesting points which they illustrate. The lesion in the two cases alluded to was ramollissement; but, as we have more than once said, softening or hemorrhage, tumour or encysted abscess, no matter; they bear all the same relation of cause to the effects we investigate. Our object in citing authorities is to show that paralysis does not universally take place on the side opposite the lesion, and for this purpose ramollissement will answer just as well as effusion of blood. Thus, in adding these two cases to the thirteen already mentioned, we have a body of fifteen facts, some of which, especially the latter, are precious, because they are recent. In medicine we require recent facts: the science should, as it were, be remade from time to time; for it is a principle in human nature to reject or look with coolness upon the testimony of ancient facts, and run with avidity after more recent discoveries, although, perhaps, they may be nothing but a revival of points known many hundred years ago, but fallen into disuse and obscurity, merely because they do not belong to the age we live in.

The same number of the *Bulletin Clinique* also contains a note of M. FOURNIER on a case in which sudden death took place from effusion into the brain: the paralysis existed on the same side as the hemorrhage: this makes up the sixteenth case; however, the latter has not yet been published; the *Bulletin Clinique* alludes to it simply as having been shown to the *Anatomical Society*.

Paralysis, when it attacks the side of the body opposite to the hemorrhage, most commonly affects both the superior and the inferior extremity at the same time: however, one is generally more affected than the other. We have remarked that the loss of movement is very frequently more complete in the upper extremity than in the lower. It is a common thing to see the arm perfectly immovable, while the leg and thigh are partially under the patient's control, and when the two limbs are equally struck in the commencement, the thoracic extremity generally recovers its motion some time before the abdominal one. In some cases of cerebral hemorrhage, the hemiplegia is confined to a single limb. The patient, for example, is unable to move his arm, while the

lower extremity remains, and the skin is perfectly motionless. Here physicians have asked whether the peculiarity depends on the particular seat of the effusion, and this question has been much debated in latter times.

Is the movement of the upper and lower extremities regulated by distinct portions of the brain? This point has been discussed at considerable length between Messrs. SERRES, PINEL, GRANDCHAMP, ROYAN, and BOVILLAUD; we may therefore ask ourselves,

Has the Hemorrhage a different Seat in the Cerebral Hemispheres, in Paralysis of the Arm and of the Abdominal Limb?

This is a question which we shall now endeavour to answer. Within the last few years, several facts have been published, with the design of showing that the motion of the abdominal member is regulated by the corpora striata and the nervous mass in front of them; while motion of the thoracic limb emanates from the thalami nervorum optico-rum, and the nervous substance behind the thalami: in other words, that motion of the leg depends upon the anterior part of the hemisphere, while the posterior portion governs the movements of the upper extremity. We have submitted this opinion to the test of facts. Here is the result we have obtained. We have collected 75 cases, in which the lesion was circumscribed in one part of the brain or other, and after having analyzed these 75 cases, the result we came to was negative. In 40 of the 75 cases alluded to, the patient was hemiplegic: the arm and leg were equally paralyzed. Now of the 40, we found the lesion situate in the corpora striata, or anterior lobe, in 21 cases; while in the 19 remaining, the hemorrhage, or softening, existed in the thalami optici, or posterior lobes. Again, of the 75 cases, we found 23 where the paralysis was limited to the upper limb alone. Now if the theory were correct, we should discover the lesions in the posterior portion of the hemispheres. What do facts show us? Of the twenty-three cases, we found two in which the lesion existed in the middle lobe of the hemisphere; eleven, with lesion of the corpora striata, or anterior lobe; this remark is quite opposed to the ideas of the authors we have alluded to; and finally, there were ten cases in which the lesion was seated in the optic thalami, or the nervous pulp behind this part.

Thus you see how the same identical lesion of motility coincided with a lesion in various parts of the brain, and that motion of the arm, at least for the 75 cases analyzed, existed with the lesion in the anterior or posterior portions of the hemispheres. Let us now examine the cases where the inferior or abdominal muscles

alone were paralytic, and in the 7th, we find twelve cases of this kind. In ten, the lesion was situated in the corpora striata, and in two only of the twelve, we found a lesion in the posterior part of the brain. Here, indeed, the numbers are more in favour of the theory which attributes motion of the lower limb to the anterior lobes, but one case is sufficient to destroy the value of the rule, and we have more; we find, as you see, two cases of twelve where paralysis of the leg co-existed, not with a lesion of the corpora striata, but of the optic thalami and parts posterior to it.

The only general consequence we are entitled to draw from the facts which we have just passed in review, is, that dissimilar parts of the brain direct the movement of the different limbs, but that in the actual state of the science we cannot say what particular point of the hemisphere commands the motion of the upper extremity, and what point governs the lower limb. This is merely a negative conclusion, but we should not neglect it on that account. In the study of medicine, negative facts have their importance as well as positive ones; they prevent us wasting our time in the investigation of circumstances whose value has been already appreciated, point out various sources of error that we should avoid, and thus render our march in pursuit of knowledge more rapid, more secure, and more certain.

Is the faculty of motion deranged, when the lesion is confined to the periphery of the brain,

When Effusion takes place merely between or upon the convolutions?

Certainly, gentlemen, we have cases where the lesion was strictly limited to the surface of the hemisphere, yet paralysis occurred with the same phenomena as if the blood had been effused into the centre of the organ. You will find an example of this in the thesis sustained by Dr. FARRI in the year 1832; it is I think No. 133 of the series for that year. Here the lesion existed at the lateral, posterior, and external parts of the left hemisphere; the author describes a coagulum as large as a sparrow's egg, situate between the convolutions at this part, and the patient died paralytic. This case is not unique; we can find other examples. Similar cases are contained in the excellent work of M. LALEMAND on the pathology of the brain and its dependencies; in his first letter, page 63, you will find one; a second is quoted in the eleventh letter, page 151: the lesion was completely confined to the convolutions, and paralysis existed. We have examples of this ourselves, and we conclude that hemorrhage occurring in superficial parts, equally produces a loss of motility, as when it occurs in the more central regions.

However, we should remark that when

the hemorrhage assumes what may be called a *chronic* form, when it takes place slowly and gradually into the gray substance, we often do not observe any paralysis; but, on the other hand, we have opposite facts to prove that when the convolutions are injured, paralysis supervenes, although the white substance is little or not at all compromised in the lesion.

At the commencement of the present lecture, we said that loss of motion also existed with effusion into the pons varolii, the cerebellum, or the spinal marrow. Let us next take up each of these parts in the order enumerated, now, however, only mentioning the mesocephale. We possess a certain number of cases in which we find

The Lesion confined to the Pons Varolii,

and we may draw from these this general principle, that the four limbs are rapidly struck with paralysis. However, in the science of medicine, we unfortunately find, at almost every step, certain exceptional cases which we are compelled to take into account. Thus, apoplexy of the mesocephale is sometimes accompanied by hemiplegia, not by general paralysis; but in cases of this kind it has been remarked that the lesion generally is situate more at one side of the pons than at the other.

COOMBE LYING-IN HOSPITAL,

AND

DUBLIN OPHTHALMIC INFIRMARY.

THE Introductory Lecture, delivered, in the above institution, at the commencement of the present session, by Mr. ROBERT P. POWER, L.R.C.S.I., and one of the Masters of the Hospital, has been submitted to our examination, in manuscript. Want of space in our columns will not allow us to insert the whole of the lecture, a great part of it being devoted to an address to students on the importance of a scientific knowledge of his art on the part of the accoucheur; but we may select the following passages for publication, with a certainty of their possessing interest for every class of medical readers. Before making the extracts, we may premise that on the death of Mr. O'HARA, the former "Master" of the hospital, the governors appointed two medical officers to fulfil the duties of the institution, which had previously devolved on one. The new masters were Mr. POWER and Mr. HUGH CARMICHAEL, the former gentleman undertaking the labours of the midwifery department, and the latter those of the Ophthalmic Infirmary. In the commencement of his lecture, Mr. POWER comments, in terms of indignation, "on the attempt," as he describes it, "which has lately been made" (by a magnate in the London Col-

lege of Physicians, before the Parliamentary Medical Committee), "to revive the antiquated opinion that the practice of midwifery was a disreputable branch of the medical art, because it occasionally involves the necessity for manual operations."

From the statements of Mr. Power, we learn that the *Coombe Lying-in Hospital* has existed for rather more than fifty years, and was established for the admission of parturient women, through the exertions of the late Mr. RICHARD GREGORY. It contains fifty beds, in spacious and airy wards, which, from its being situated in a densely populated part of Dublin, are continually occupied. The account of the circumstances under which the hospital was erected, which follows the subjoined statistical statement of cases, will be read with feelings of painful interest:—

"The registry of cases kept in the house for the six months preceding the first day of the present month of November (1855), shows that, within that period, of 713 females who have been delivered within its walls, 626 labours proceeded according to the usual routine of nature, and eighty-seven presented departures from that course. Of these latter, nine were cases of breech presentation, fourteen were abortions, two elbow presentations, five twins, four attended with hemorrhages, seven instrumental, of which latter, in two, the crotchet was used to break up the child in order to extract it; in two ruptured uterus, and in five retained placenta, occurred. The remainder of these cases did not present any particular event, although coming under the head of irregular labours. There is also attached to the hospital what is termed an *externe* department, affording assistance to females who, from any particular circumstance, cannot avail themselves of the comforts of the house, and are confined in their own homes. The registry of the latter class of cases shows, that, within the same period, 811 females were delivered, and attended through their confinements, without the doors of the hospital. Of this number 702 were natural labours, and 109 irregular. Of the latter, thirteen were breech presentations, twenty-nine were abortions, eight twin cases, one triplet (three children at a birth), eight cases of hemorrhage, two instrumental, nine retained placenta, five footlings, two funis presentations, one arm presentation, two placenta presentations, and three convulsions, making in all an aggregate of 1524 cases, of which 1328 were natural, and 196 were variations therefrom. These two abstracts show that the external department comprises the greater number of cases, which, upon first consideration, might appear extraordinary, where so much poverty prevails, for comforts like those which are to be met with in a well-regulated hospital seem thus to have been neglected, in cases

where the sick female stands so much in need of aid.

"But tempting as is a comfortable asylum in these instances, to poverty, in its most abject form, for abject indeed it is in the neighbourhood which surrounds us, nevertheless it is not sufficient to overcome that *vis* of nature which induces the mother to cling to her little home and family, until the last moment at which she conceives she can remain with them. The consequence is, that, in a vast number of instances, females who really intend to become inmates here during the period of their confinement, are overtaken in their illness, and thus have their own homes unexpectedly rendered the place of their labours. That such is the case will at once appear evident from the following facts. Before this hospital was established in its present form, that noble institution on the north side of the city, the *Rotunda Lying-in Hospital* was the only one in Dublin. The distance, however, between it and this spot is so great, that although the length of time required in the distressing journey was, from repeated occurrences, made strikingly evident to females who resided in this neighbourhood, still the feeling to which I have just alluded could not be abated; and as external assistance to females in the parturient state was not recognised by that hospital, those who wished to avail themselves of its aid, could only obtain it by becoming inmates therein. The consequence was, that, in many instances, females, who began to proceed thither from the liberties, were overtaken in their labour on their way to the institution, and the wretched halls and alleys of this impoverished district became the places of their confinement, perhaps in the dead of night, and at the most inclement seasons of the year, for the bitter destitution of the inhabitants precluded the possibility of a conveyance being obtained thither, even on such occasions as these. The scenes that sometimes then presented themselves were of a most distressing character. A wretched fellow-creature, surrounded, at this event, by her small and equally wretched family (who flew to her at the moment), then giving birth to an infant under these humiliating circumstances, at once struck the heart with compassion in its most touching form, and regret filled the mind for the misery from which such scenes could proceed; while the cries of the new-born babe fell on the ear, its wailing sounding like moans at the hereditary misfortunes of its race, of which it now was come to bear its part. Whether such misery was the result of inherent gradation on the part of its victim, or indifference in quarters professing to care for their welfare, we are not to inquire, but let us trace the effect to its cause, and seek as the sufferers may have been in the abyss

of degradation, and forgetting, for a moment, that blight of our common country,—party: this will be admitted by all who have witnessed such scenes, that they were not more the scourge of those who were exposed to them, than they were disgraceful to those whose duty it was to remedy the evil.

“ Since, however, the establishment, in which we are assembled has been in operation, such truly pitiable occurrences have altogether ceased, and with them those unfortunate results, then so prevalent, as the death of the infant, and recovery on the part of the mother with consequences so unhappy as to incapacitate her from the future fulfilment of her maternal and domestic duties. Indeed to such an extent did events like these prevail, that a respectable practitioner, who resided for a long time in this part of Dublin, at his death bequeathed an annual legacy for the establishment of a Lying-in Hospital in his district, after having spent the best part of his life in representing the necessity of such an institution to Government, but to which a deaf ear was turned. Through the kindness of Doctor Bell, one of our most anxious supporters, and than whom no one is more conversant with the former miseries of pregnant females in the liberties, that legacy is now devoted to the support of this house, and the delays which used to lead to the events I have described, is remedied, a skilful pupil being now sent from this hospital to take charge of the female, and conduct her through her perilous situation.”

CASE OF
OBSTRUCTION OF THE BOWELS,
WITH SUCCESSFUL OPERATION FOR THE
FORMATION OF A NEW ANUS.

To the Editor of THE LANCET.

SIR,—I publish the following most interesting case at the request of several medical friends, detailing the state of original imperforation, the means used for its remedy, and the time when the obstruction commenced, its progress, and the effects produced on the constitution of the patient until relieved by the operation which has led to the publication of the present article. The relation of the patient's subsequent condition, and the treatment, I have given in a condensed form.

I have added a few practical reflections, calculated to render it more acceptable to the senior members of the profession, and to whom it is my more especial object to be useful. I

JOHN LINDSAY, Surg.
23, Northumberland Street, Glasgow,
Nov. 24, 1835.

Case.—S. P., a boy, was born of healthy parents in April 1829, with imperforation of the anus. The surgeon whose attendance was required, had several difficulties to contend with in making an opening into the rectum, as there was no protrusion of the integuments between the nates, nor any other mark by which to trace the situation of the gut. Several attempts failed, but at length an opening was made at the lower end of the os sacrum, at the root, and towards the left side, of the os coccygis. The opening thus formed was kept patent by sponge tents and other means, but it was small, and liable to obstruction from slight causes.

On the recommendation of a friend, the child was first brought to me in December 1829, he being then eight months old. At about the same period he was examined by Dr. Weir, then senior surgeon to the *Royal Infirmary*, who recommended the use of bougies and enemata, which were accordingly had recourse to daily; the former were gradually increased in size, for the purpose of procuring a regular evacuation of feces and enlargement of the passage, which, with a few powders of *Submuriatis Hydrarg.* et *Pule. Rhei*, had the desired effect of improving the general health. Notwithstanding, however, the feces were passed involuntarily.

In course of time the child became a stout healthy boy; but when running about with his companions, having no power of retaining his feces, they were constantly oozing through the artificial anus, causing always a disagreeable smell about his person, although his mother, who was very cleanly in her habits, paid every attention to his comfort, by washing him frequently, for the convenience of which the under part of his dress consisted of petticoats only.

The prospect of their son arriving at manhood under so loathsome an infirmity, was distressing and humbling to his parents, whose fears in this respect were, in the autumn of 1834, changed to feelings of a more painful description. At that time his health began to decline; his evacuations per anum were scanty, and passed with difficulty, even although rendered almost fluid by medicine. His belly grew large, while the rest of his body became emaciated; the functions of digestion became irregular and impaired; his appetite fell off; and, ultimately, hectic fever was superadded, which reduced his strength to such a degree as to confine him constantly to bed.

Such was his condition towards the end of January 1835, when I was desired by his father to visit him. He had now arrived at the age of five years and three quarters, and during the last four months his health had been obviously and rapidly declining. Language would scarcely describe the miserable appearance he presented. I no longer beheld the little plump ruddy boy which he for-

merly was, and his extremely large abdomen, which was as hard as board, formed a painful contrast with his exceedingly emaciated chest and extremities.

Besides the hectic symptoms, his mother mentioned that for several weeks previously he had obtained no evacuation per anum, except what was produced by the daily use of the bougie and the purgative enemata, especially the latter, *and that only during the time the glyster-pipe was in*, when a little feculent matter escaped by the side of it, which generally stopped as soon as it was withdrawn. Such, she said, had uniformly been the case during the time specified, although the dejections were of a fluid description. These symptoms led me to suppose that a flap, or false membrane, had formed near the extremity of the rectum; which, acting as a valve, prevented the exit of feces, except during the time of its being pushed back by the introduction of the glyster-pipe. To ascertain this, I proposed to examine the parts with the finger, which I consider the best probe on such occasions. His mother's feelings, however, were overcome so much by the terror of cutting, that she even objected to allow the examination, especially as she considered his case to be hopeless, connected, perhaps, with the disagreeable reflection, that although his evacuations were reinstated as before, yet still the boy's prospects for the future were any thing but pleasant. Purgative enemata, with the use of bougies of a small size, were, therefore, continued, and by constant perseverance, they succeeded, at times, in bringing away a little feces, which had the effect of prolonging his miserable existence.

On the 9th of February following, however, I was requested by his father again to visit him, when he promised that nothing should stand in the way of doing what might be considered necessary, the boy having become much worse for a day or two previous, in consequence of the usual means failing to have the desired effect. Accordingly, on the day following, I visited him, at their residence, about two and a half miles from Glasgow.

Setting a table opposite the window, I had the little patient laid upon it, with his abdomen downwards, which was prevented from pressing on the table, by putting one pillow under his breast, and another under the head of his thighs. On attempting to introduce my little-finger into the artificial anus, I was surprised to find it too small for his admission, even although considerable force was used, it being not larger than to allow a goose-quill to pass with ease. The integuments around it, which were very hard, appeared to be nearly destitute of either muscular or cellular substance, as if the parts were cicatrized after having been in a state of ulceration, which I was informed had indeed been the case. The pre-

sent opening was extremely imperfect, being limited or confined by the os coccygis and the last bone of the sacrum, rendered hopeless any attempt at enlarging it, which was, indeed, the less desirable, as it would have left the patient to pass the feces involuntarily as before.

The probe could be passed about two inches nearly perpendicularly downwards (considering the position the boy was in at the time), the point of it being close upon the cervix of the bladder, and about fifteen lines inward from the perineum.* No flap or false membrane could be detected by the probe, nor could any assistance be obtained by the eye, on account of a little feces escaping.

Under these circumstances, it occurred to me that the most proper way of rendering him relief, would be by *making a new anus, sixteen or eighteen lines nearer the scrotum*, by that method avoiding the os coccygis altogether.

The objections to this were principally these; first, the depth of cutting required before entering the gut; secondly, the danger of wounding the bladder; and, lastly, the danger of injuring the bulb of the urethra.

Keeping these dangers in view, and retaining the probe in the old anus, I took a straight-pointed bistoury, and holding the back of it towards the bulb, thrust it inwards, about an inch, at that point where the raphe terminates posteriorly, and enlarging the opening a little towards the sacrum, I withdrew it.

On introducing my finger into the wound, and taking the probe in the other hand, I could easily ascertain the distance remaining to be cut; then removing the probe and substituting in its place a director, which I desired an assistant to hold, so as to press its point as much as possible outwards, I scratched through the intervening space with a scalpel, when, to my great satisfaction, the instrument was brought out soiled with feces. I now pushed my fore-finger right into the rectum, when a large quantity of feculent matter escaped. A mild purgative enema was then thrown up, which brought away a great quantity more. In this evacuation there was a plum-stone, which the patient had swallowed four and a half months previous, during the fruit season in autumn.

This stone, it will now be observed, had been the cause of the obstruction, and not any flap or false membrane, as I had at first supposed. The stone, after passing the stomach and intestines, had made a permanent by the side of, and rather

* It is probable, considering the situation of the rectum, and the pressure of the bladder upon it, that there is four months previous to the formation of the gut may have been situated in the rectum near the perineum.

the coccygis, from which an account of the hard and unyielding state of the parts surrounding the artificial anus, and being greater in diameter than the opening itself, it had been prevented from escaping. A constant tenesmus had tormented the patient, while on every occasion of his going to stool the stone, filling up the diameter of the outlet, prevented any feculent matter from escaping, except when pushed back by the glyster-pipe, or a small bougie, as before stated.

Every experienced surgeon knows that in private practice it is rarely possible to get a patient to comply with all that is desired, especially in surgical cases, and it was so in this instance. The nature of his disease rendered the little patient peevish and fretful, and made him averse to be examined. Indeed, the first and only opportunity of examination was immediately before operating. The probe then slipping past the stone, as it was introduced, although turned in every direction, gave no indication of its existence, while the escape of a little feces, as before observed, prevented any assistance being obtained by the eye.

A piece of candle, four inches long, was now introduced as a bougie, and was secured by a pad and T bandage, the abdominal part of it being made of flannel. This was about one o'clock p.m., on the 10th of February. At four p.m. of the same day, he had another large evacuation of feculent matter by the new opening; after which, a new candle bougie was substituted in place of the former, which was partially melted. He was then put to bed, and enjoined rest, with mild diet: he remained in this state until about midday of the 11th, at which time he had another evacuation by the new anus, from *ss of Ol. Ricini* which had been administered that morning. A wooden bougie, made very smooth, of seven and a half lines in diameter, was now introduced, and was ordered to be kept in and out for four hours, alternately. The abdomen had by this time become pretty empty and flaccid; pulse 150; skin hot; otherwise the boy was in good spirits, and had passed urine twice within the first twenty-four hours after the operation, quite freely, and without uneasiness. *R. Submuriatis Hydrarg. gr. iv; Pulv. Opii gr. j. M. Chart. No. iv, quarum sumat unam quaque hora quarta.*

12. Skin more cool; ordered a new bougie of nine lines in diameter, et *Ol. Ricini* *gras mane.*

13. Skin again hot; pulse 140; the parts around the anus are much inflamed. The bougie was renewed, and a poultice of bread and milk was applied to the anus, to be renewed every sixth hour. The bougie was kept in for half an hour, and out for half an hour, on account of the degree of inflammation, and to be coated each time previous to introduction with a thick

layer of the following ointment. *R. Azungui Ricentis siss; Ext. Belladonna, Acet. Plumbi, aa 3ij. M.**

March 5. General health much improved. The new anus looks well; it is open at the time of withdrawing the bougie, but closes gradually by corrugation; very little pus, the parts being nearly all covered with a smooth membrane; nothing coming by the old anus but flatus. Bougie ordered to be kept in only two hours every morning.

17. The motions have been passed regularly by the new anus. He has been walking about daily since the 10th instant, by which exercise, a small quantity of feculent matter is forced out by the old anus, especially when the bowels are loose.

R. Nit. Argenti gr. xx; Ag. Distillat. 3j: solve. Inject a drachm into the old anus morning and evening; a piece of lint well covered with *Ung. Resinos.* to be afterwards introduced, to produce in the first instance a rawness of surface; after which, the solution of *Nit. Argent.* being discontinued, *Tinct. Canthar. Venic.* is to be substituted, and the pledget of lint, with the ointment, continued.

This course was persevered in for several weeks, with very little advance towards closing up the first opening, the main difficulty in accomplishing which was, the manner in which it had been excavated or hollowed out (if I may use the expression) by the great pressure of feculent matter, previous to the operation being performed, which has made it like an inverted cone, the outlet being the apex.

Considering such to be the case, I thought the only rational way of closing, or, rather, of filling up, the posterior opening, would be to treat it as a fistula. So on May 19th I divided the space intervening betwixt the old and new opening, with a probe-pointed bistoury. When for this purpose I introduced my finger into the new anus, the sphincter closed round it with great firmness, which convinced me of his being able to retain his feces by the new passage, if the old one was filled up. A piece of oiled caddice was introduced into the wound, and secured by a poultice and a T bandage. A teaspoonful of paste, in imitation of "Ward's Paste," was applied three times a day, for the purpose of assisting to form granulations.

This course was continued long enough to convince me, that something else was necessary to be done before sufficient granulations could be produced for filling up the cavity, which desirable object was considerably retarded by the pressure of feces often-times displacing the dressings.

* This ointment is highly recommended by Daytzen, who used it in cases of Abscess about the anus with decided advantage. See LANCET of March 19, 1837, page 838.

June 26. Coarse green flax was substituted in place of the lint, and covered well at each dressing with the following:—*R. Ung. Resinos 3j; Pulv. Canthar. Vesic. gr. xx. M.*

Previous to the introduction of the flax at the dressing morning and evening, 3j of the following lotion was thrown in with a small syringe:—*R. Decocti Gentiane lb iss; Acid. Nitros. 3ij. M.*

July 21. The flax tent, with the ointment, comes in contact with every point of the cavity, and is with the lotion and mixture already producing copious granulations, which are springing up rapidly. His health is excellent; no feculent matter has come by the posterior part of the opening for the last fourteen days, and the pledget of flax, which is renewed every morning, and which I direct to be kept as much as possible towards the sacrum, remains in from the one dressing to the other, without being displaced as before. The bougie is to be introduced into the new anus once a day, and immediately withdrawn.

From that time he was allowed to walk about, and on August 26 the medical remedies were discontinued, in consequence of the posterior cavity being completely filled up, so that neither feculent matter nor flatus could escape by it. Being now able to retain his feces at pleasure, he was dressed in male attire, a circumstance that pleased him very much.

Remarks.—This case being brought to a successful issue, it may not be improper to introduce a few practical reflections, suggested by what is contained in the foregoing case, and applicable to those of a similar nature, although not intended to apply to cases of imperforation in general. Having waited for a day or two, or, in some cases, for three or four days after the birth of a child with imperforation of the anus, in most cases the integuments between the nates gradually protrude, and become of a livid or black colour, from the pressure of the meconium within. There can, then, be no difficulty in determining how to proceed. With the pointed bistoury we make an opening, and, enlarging it with the aid of a director, nothing further is necessary than to keep it patent, and attend to constitutional symptoms, until the infant recovers.

But in cases of imperforation of the anus, where no such protrusion takes place, and where no other mark indicates the position of the rectum, we are beset with greater difficulties.

With a view of lessening these difficulties, I would suggest proceeding as in the case of S. F., by making a small opening with a narrow bistoury, just large enough to admit the probe on the left side of the os coccygis. If, with the probe, we succeed in reaching the gut, it can easily be ascertained, by its

depth and direction, how, and in what way, we may come at the same point, by cutting or piercing from the perineum, at the posterior termination of the raphe, as before detailed; after which, the small opening at the root of the os coccygis may be conveniently closed up by adhesive plaster.

Attention to these directions may, I conceive, serve to lessen the difficulty in making a proper anus at first, in cases where the gut can be found, by piercing at the root of the coccyx; and we may rest assured, that we never can make an artificial anus in any other situation than the one here recommended, with a probability of rendering the individual comfortable through life. There we have it at the most depending part of the trunk, so that no sac can form beyond it. We have the probable existence of that essential part of the anus, the sphincter muscle, without which we cannot retain the feces; we have also the two nates, like powerful sentinels, both adding strength to the passage within, and affording security from injury without.

For keeping the anus patent, after it is made, I would prefer the wooden-bougie to any other. The sponge-tent is irregular in its surface, and does not continue of a uniform diameter, nor is its elongation so complete as is required.

The wooden bougie can be made of any size, or of any form required, and never alters its figure by use; unguents of any kind, with which it might be proper to cover it, adhere better to a bougie made of wood, than to those made of bone, ivory, or metal. It is, besides, an advantage pos-

essed by the wood, that it never communicates the same unpleasant sensation of cold to the parts as is the case with any of the others, unless previously immersed in hot water, which render them unfit for receiving a coating of ointment, if thought necessary.

The kind of bougie which I have found to suit best is made in this form, very much like that of a candle, with a rim, or border, at the farther extremity, to prevent it from slipping in, the pad and bandage, without the aid of tapes, serving to keep it from coming out. The extreme length of those which I have used is generally three or a quarter of a yard, trying to reach the half of the rectum. I had one of hogany, or black mahogany, when too hard

of too small, a new one can be substituted at a very trifling expense.

For a tent or pledget, my experience leads me to think that green flax is preferable to caddice. Flax accommodates itself with great accuracy to the surface with which it comes into contact, and by its roughness it provokes the formation of granulations, while it is sufficiently soft to yield to and protect them when forming. The size of the pledget requires to be reduced from time to time, as the cavity fills up, until it is finally rendered unnecessary.

It will be observed, in perusing the above case, that from the 17th of March until the 26th of June, the time was in a manner lost in vain endeavours to close the old anus; this partly arose from the size of the cavity being so wide as to always allow a large quantity of feculent matter to descend and displace the dressings, but principally from the actual inefficiency of the applications. Some little progress was indeed made, but nothing compared to what was afterwards attained, by the use of green flax, cantharides ointment, and lotion, the paste at the same time assisting in an inferior degree.

COLICA SPASMODICA,

FOLLOWED BY

INFLAMMATION,

TERMINATING FAVOURABLY.

To the Editor of THE LANCET.

SIR,—I beg to transmit the following case for insertion in the pages of THE LANCET.

I am, Sir, your obedient servant,

MATTHEW GIBSON, Surg.

Govan Haugh, Glasgow,

Dec. 22, 1835.

CASE.—John Maxwell, aged 20 years, while engaged at work on the night of Thursday, December 18th 1834, and in a state of profuse perspiration, took a large draught of cold water, and at 10 o'clock, an hour afterwards, was seized with a pain in the abdomen, exactly over the region of the caput cæcum coli. By 1 a.m. it had increased so much that he was forced to leave work. On arriving at home he swallowed two ounces of Epsom salts, which were in the house, and in half an hour afterwards he had a motion in his bowels, but felt no ease. At six the pain had so greatly increased, accompanied by a disposition to vomit, that his friends requested that he should be bled.

At eight, he complained to me of the same pain at the above-mentioned part, which was increased much upon pressure; abdomen not much swollen, and

was soft; tongue furred; pulse not much altered; the bowels had been constipated for two days before. He was ordered *Pulv. Opii* gr. ij; *P. Rhei* ʒj; *Magnes. Ut.* ʒss. M. Divide in partes tres, sum. j, q. q. 2d hor.

Dec. 19, 3 p.m. Pain still continues, and is fixed; pulse quick; tongue very much furred; akin hot and dry; headache and pain in back; some thirst; had vomited the powders; no stool. R *Submur. Hydr.* gr. vi; *Opii Pulv.* gr. ʒ. M. sumat statim, repet. idem q. q. 4th hor.

Saturday, 20. Was called in haste this morning at five o'clock. Is much worse; pain considerably increased, and extending across the belly, aggravated very much on the slightest pressure; did not vomit the powders; pulse 80; no stool. Mittat sang. e brach. xvi oz. Applic. sinap. part. dol., et cap. *Ol. Ricini* ʒi, statim. Si non respon. in hor. quat., hab. *Sulph. Magnes.* ʒij. q. q. hor. donec amp. purg. Enem. domest. statim.

12 noon. Two hours after the oil had been taken he vomited; passed the enema almost immediately after it was given, mixed with no feculent matter; pain not in the slightest abated; general tenderness throughout the abdomen most intense over the caput cæcum coli; pale anxious countenance; great thirst, frequent vomiting, and flatulent eructations. Admov. hirud. duodecem ad dol. part.; postea foment. calid. Enem. adhib. statim. Contin. *Sulph. Mag.*

4 p.m. Received notice that he was considerably worse, and on arriving I found the former symptoms much aggravated; pulse 100, full; tongue the same; right cheek flushed; great anxiety exhibited in countenance; skin covered with perspiration, and is unable to move himself in bed; had vomited the salts; enema still retained. In consequence of some misunderstanding the leeches had not been applied. The former blood not cupped, but several parts of it covered with lymph. Mittat sang. ʒxvi. Admov. hirud. statim. Rep. enem. Cap. *Ol. Croton* gtt. ijss.

10 p.m. Two hours after the croton oil had been taken he vomited some glairy kind of mucus; passed both injections, with no stool, but it had a feculent smell; blood slightly cupped and buffed; takes nothing but water-gruel; pain, with general tenderness, no better; pulse 100. R *Pil. Al. c.* Col. unum q. q. 2d hor. sumend. tere in pulv. Impon. emplas. canth. vesicat. ad abdom. Rep. enem.

21, 10 a.m. Passed a bad night, has taken five pills; no stool; blister rose well, and thinks the pain is rather easier; pulse 96; other symptoms the same. Applic. catap. emol. ad vesicat. Cap. pil. col. duas statim, et idem adhib. q. q. 2d hor.

8 p.m. Has had the pills regularly, but no passage in bowels, other symptoms much the same. Contin. pilula.

Monday, 22, 10 a.m. Has had the pills regularly since last night, and has had thirteen stools, which are feculent and of a brownish colour; the first stool was about an hour after last night's visit; expresses himself as considerably better; the hand can be pressed on the abdomen with great freedom, except above the caput caecum coli, which is still tender; pulse 86, soft; skin moist; still some thirst; no more vomiting; did not rest much, from purging. Contin. cataplasm. Discontin. omnia medic.

10 p.m. Has had no more stools, but continues easy; blister discharging. Quies, cras mane.

Tuesday, 23, 10 a.m. Pulse the same; has had several stools since last night, which are mixed with a flocculent kind of matter; tongue clean; still some thirst; in other respects pretty well.

Wednesday, 24. Has had six or eight stools since yesterday; thirst diminished; blister nearly healed; scarcely any pain in abdomen; pulse 82; tongue nearly clean; beginning to feel a little hunger; ordered some mild soup. From this date he gradually continued improving, without the aid of any more medicine, his bowels being freely opened once and twice every day, and in four weeks he was engaged at his usual employment.

Remarks.—In this case, it would appear from the prevailing symptoms, that both the beginning and the termination of the bowels were in active operation. That the greater portion (if not the whole) of the small intestines were acting naturally is certain, from the retention of the larger part of the medicine, and the consequent violent purging which ensued after the subsidence of the complaint; and that the greater portion of the large intestines was also acting naturally, is equally certain, from the expulsion of the different enemata which were given. Now the fact comes to be this; that the complaint must have been either at the end of the small or at the beginning of the large intestines. In my opinion the complaint was altogether in the caput caecum coli, which is proved by the pain commencing and continuing fixed in that part, and also from the observations previously made.

What was the pathology of this affection? Was it a case of simple obstruction in that part from constipated bowels, or a loss of muscular power in the part, and consequent over-distention, as Dr. Abercrombie supposes all cases of colic to be? Or was it spasm, which Dr. Cullen's views would lead us to believe? Or was it a case of common inflammation?

For my own part, I should consider this to be a case of obstruction, not altogether, however, arising from constipated bowels (although the patient had had no stool for two days previous), but, as Dr. Cullen would

say, from a spasmodic contraction of that part of the gut brought on, I have no doubt, by the large draught of cold water which the patient had drunk whilst perspiring profusely, his bowels being sluggish at the same time, both co-operating together, by giving a sudden check to the perspiration, and nervous system, and thereby bringing on the disease in question, which ended, from the severe symptoms which ensued, in inflammation.

CANCER OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—The importance of clinical lectures above all other lectures is unquestionable, and all men of science who feel for the welfare of a profession which stands first in the scale of humanity, must rejoice in the adoption of a mode of instruction, which but a few years ago was unknown in the British metropolis. Much also are the public indebted to THE LANCET for the wide diffusion and the consequent practical benefits of such lectures, which, had they ever been delivered at all, would, without the efforts of that journal, have been confined wholly to the limited circles in which they are pronounced.

In THE LANCET of November the 7th, in the clinical lecture of Dr. Elliotson, a case is given of "Chronic Inflammation of the Uterus," which, when I read it yesterday, impressed me very forcibly with an opinion, that its details and conclusion might tend to lead to much practical error. "The next case," the lecturer observed, "is one of diseased womb, in Elizabeth Warren, aged 29, a married woman, without children. Now this is to be noticed, that she was married and had had no children." The leading circumstance in the history of this case is, that about three months previous to her admission into the hospital, she awoke in the morning with a violent pain in the hypogastric region, accompanied by "a severe bearing down." "She had menstruated regularly before, and very copiously." "A month after this attack," which was the monthly period, "she had a profuse discharge of a black colour, containing large clots of blood," and this lasted "for five weeks." (On her admission to the hospital, the uterus was found to be so diseased, as to induce a doubt whether it was not of a scirrhus (cancerous) nature. She obtained under the treatment adopted (bleeding, mercurials with opium), and was in the temporary absence from town, as "relieved."

Now a leading pathological point in this case is, that after amendment took place,

on the 12th she had no pain," was examined was made as to the *then* actual state of the uterus. How came this to be neglected, which would have assisted so mainly to form a right conclusion on the nature of the disease? Before any treatment was adopted, Dr. Elliotson says, "Now I examined this woman myself, and found the uterus very hard;" "all seemed to be solid and fixed," "firm and fixed."

The neglect, then, of an *after* examination, when under amendment, to ascertain whether the uterus was *then* "solid and fixed," or softened and more compressible, has thus consequently involved this case in a supposed doubt as to its nature; and in doubt Dr. Elliotson concludes his observations on the case: "But I will not say at this moment whether the disease was simple induration, or *scirrhus*, in the modern exclusive sense of the word," all of which embarrassment might have been avoided.

The directly probable state of this patient was that which Dr. Elliotson supposes might have been the case, viz., that "the uterus had fallen suddenly into a state of inflammation," and the circumstance of her not having had any children—and having menstruated "very copiously" previously to the attack, confirms the probability of the opinion that there existed a predisposed state for such an attack. But, on the other hand, all the history and circumstances of the case as detailed, entirely preclude the supposition of a doubt that in its *then* reported state, it actually partook of any thing like the nature of *scirrhus* in the modern exclusive sense of the word."

In my "Inquiry into the Nature and Action of Cancer," published in 1805, I attempted to show and establish, that *scirrhus* was the result of "permanently altered structure" and "acquired actions" leading to cancer as a *necessary* consequence. This doctrine was opposed to the then prevailing opinions, that the disease depended upon some "specific poison," some "leaven," or "ferment" or "fomes," or some "animalcula" of an hydatid nature.*

This doctrine, supported as it was by the facts connected with the origin and progress of cancer itself, necessarily *slow* in its origin, was generally admitted, and so far influenced Dr. Baillie at the time, as to induce him, when he published his third edition of "The Morbid Anatomy," to withdraw certain opinions which he had formerly stated relative to the *predisposition* of parts as being *necessary* to produce the disease, when

speaking of the "*scirrhus* and cancerous stomach."

So much is stated in application to the case in question. There never was a sudden attack the *immediate* result of which was *scirrhus* "in the modern exclusive sense of the word."

The morbid, the *permanently* morbid altered structure, must be the *progressive* effect of some *former* injury or disease of a part, wherever *scirrhus* or cancer exists.

In all this the late Dr. Denman concurred, confirmed as the concurrence was by his own able and extensive observation and experience. *Scirrhus* of the uterus was never known to exist in a menstruating woman of twenty-nine, and therefore could not have existed in Elizabeth Warren's case; but which state the diseased condition of the uterus would necessarily lead to at some *distant* period, if it were not wholly removed, or if the patient were not previously destroyed by some fresh attack of inflammatory ulceration of the organ itself.

All the symptoms of Warren's attack proved it to be *inflammatory*,—*sudden*, and not *previously slow* and *progressive*. Her "copious menstruations" previous to the attack, sufficiently indicated the state of things, followed, as it was, by the after "profuse discharge of large black clots of blood," which lasted for "five weeks," and by which nature herself very sufficiently and impressively pointed out the treatment for relief, and which was adopted in this case, but in *part only*, and not completed. She was "relieved," but not wholly so. The treatment, therefore, as a cure, was unfinished, and here was the error. The patient should not have been discharged as "relieved," but the state of the uterus absolutely ascertained by examination, the treatment continued, and the case not lost sight of, until the disease was wholly removed, or found to be incurable.

As these observations may be applicable to other and similar cases which may occur, I have thought it practically important to send them for publication, which, even if, Mr. Editor, you should not agree with me in my views, I yet claim, at your hands, upon the just principle which has hitherto influenced the conduct of THE LANCET,—viz., that I may be heard, and, if wrong, that I may be set right, but if right, that that which is right may be established and promulgated. It is not, in this individual case of error, as I conceive it to be, that I respect Dr. Elliotson less, but that I esteem the promulgation of truth more.

Amidst the labours of an extensive private practice, no honourable man can fail to entertain feelings of respect for the public exertions of Dr. Elliotson in the general cause of science, which stand so pre-eminently in contra-distinction to those of that

*The Poison-mongers was the late amiable Dr. Baillie, who, in a book published in the same year, 1805, supposed, that a cyst which he found in the uterus was actually the very apparatus of the cancer virus or poison! This notion was entirely his own. It could not have been taken from any of John Hunter's Manuscripts.

court "blow-fly," Sir Henry Halford,—the once wriggling maggot, Vaughan.

I remain, Sir,

Your obedient humble servant,

SAMUEL YOUNG.

Strutta, East Looe, Cornwall,

Dec. 26, 1835.

FREE GASES IN

DIABETIC URINE.

To the Editor of THE LANCET.

SIR,—For some months I have been much interested with respect to the free gases *supposed* to be contained in healthy urine, and have put the question to the test of experiment, by submitting the urine of different healthy persons to the action of my air-pump, in the manner formerly explained in the pages of your very valuable Journal, but I was not enabled to extricate a single bubble of gas from any specimen of urine experimented on.

Not deterred, however, by this, I was again induced to experiment on the urine of a sailor, belonging to this port, who had long been afflicted with that incurable and most severe disease, diabetes. This person, a dependant in the Sunderland Workhouse, came at two different periods to our infirmary, and in my presence passed twenty ounces of urine each time, in the most steady and correct manner, so that no gases were lost during micturition. The exact proportions of gases which ten ounces of this urine contained at the first micturition, were as follows:—

	Cubic Inch.
Oxygen gas06
Carbonic acid gas02
Nitrogen gas19
	—
	.27

From the second of the two micturitions, which was performed about five days afterwards, I obtained from a similar quantity of urine the following gases:—

	Cubic Inch.
Oxygen gas03
Carbonic acid gas02
Nitrogen gas26
	—
	.31

I need not point out to the medical faculty the importance of these facts. I beg that they may be compared with what I have published in the pages of THE LANCET, with respect to human arterial and venous blood. I remain, Sir, your most obedient servant,

W. REID CLANNY.

Sunderland, Dec. 24, 1835.

P.S. I forgot to mention, in a former communication, that in every experiment with my new safety-lamp, I used bladders of coal-gas, or explosive atmospheres of coal-gas and atmospheric air.

MEDICINAL PREPARATIONS OF MANGANESE.

To the Editor of THE LANCET.

SIR,—Among the numerous metals which have been introduced into the class of medicines, I have never observed any preparation of manganese. This metal is principally employed in the art of dyeing, and for chemical purposes, but I now wish to introduce it as a remedial agent. About two years ago I prepared a chlorine solution of that metal, and introduced it as an alterative and tonic, but afterwards found it a valuable medicine for epistaxis. Several remedies are now employed for this complaint, under the name of styptics, but I believe they are not to be relied on in severe cases of hemorrhage; and the acetate of lead is frequently objected to, on account of its irritating property.

It will be useless to mention the number of cases of epistaxis which have effectually yielded to the chlorine solution of manganese, as I have given the form for preparing it, and will leave the surgeon to judge of its application from his own experience.

To prepare the chlorine solution of manganese, put into a bottle which will hold about two pints, one ounce of carbonate of manganese previously mixed with three ounces of distilled water. Let a current of chlorine gas be slowly passed immediately upon the mixture (by means of a glass tube connected with the retort whence the gas is distilled) until the manganese is dissolved. The solution must then be put into a flask, and a gentle heat applied for a short time, when the mixture will become clear. Filter when cold, and add one ounce of alcohol.

This process occupied a great deal of time, and was attended with some little trouble; therefore, instead of using the chlorine gas, I have since prepared a muriate of manganese, which is not attended with trouble, and its medicinal properties appear to be precisely the same. To prepare the muriate, take one ounce of carbonate of manganese and two ounces of muriatic acid, mix them together in a flask, and apply the heat of a lamp for a few minutes. When the mixture is cool, filter, and add one ounce of alcohol.

With respect to the alterations in the constitution of this medicine, I have not observed any sufficient proofs to enable me to speak much in its praise, but in some instances it has

proved a very good substitute for antimony, iodine, &c. For syphilitic eruptions it may be given, in combination with sarsaparilla, with a very good effect. In some obstinate cases of chronic rheumatism, it has also been given with advantage. The following will be the best mode of administering the muriate of manganese:—

As an alternative, ten or fifteen drops may be given twice or three times a day in water.

For epistaxis the same dose may be given, to be continued for a week or ten days, or until a sensation of vertigo comes on, which usually takes place. If the hemorrhage continue for some time without intermission, and the surgeon think it necessary to check it immediately, give ten or twenty drops every quarter of an hour, until the bleeding stops, or until vertigo is produced, and continue its use for several days after. In every case which has yet occurred, the second dose has always succeeded in stopping the discharge, and without producing any subsequent unpleasant sensation. The muriate will sometimes produce nausea, when the bowels are in a disordered state; therefore a dose of some aperient medicine should first be given, if time will allow, and also after vertigo is produced an aperient must be given.

For hemoptysis this preparation has not yet been given with success. However, it has only been tried in two or three cases. When combined with Sp. Eth. Nit. and Inf. Anthemidi, it has proved serviceable in some cases of hematuria, but it must never be given when fever is present.

By giving to the foregoing a place in your valuable journal, you will, Sir, oblige your obedient servant,

HENRY OSBORN, Chemist.

Southampton, Jan. 5, 1836.

AMAUROSIS,

FOLLOWING

SUPPRESSED FEELINGS OF PASSION.

To the Editor of THE LANCET.

SIR,—I send you the following case, thinking it worthy of a place in your journal; it occurred in the *Hotel Dieu*, Paris, last summer, where I was then studying. Your obedient servant,

J. I. IKIN, Surgeon.

Reading, Yorkshire, Jan. 4, 1836.

—, *et*at. 35, tailor, of Paris, of a sanguine temperament, was admitted into the *Hôtel Dieu* on the 15th of June, 1835, for an affection of the head, accompanied with amaurosis. He

states that he has been subject to violent pain of the head for two years and a half, but that it has become much worse lately, and that he has been totally blind for five months. The immediate cause of his blindness he attributes to a violent mental emotion, experienced whilst at a review of the National Guard, of which he is a soldier. Being strongly, and, as he considered, unjustly reprimanded by his captain, and not daring to reply to his superior officer, he was obliged to contain his violent feelings, in consequence of which partial blindness, attended with a strange sensation in the head, was the immediate result. This blindness rapidly became worse, and at the end of a month he was perfectly blind. For this affection, as well as for the pain of the head previously, he was repeatedly bled, both in the arm and the foot, and had cauteries applied to the head &c. but without the slightest benefit resulting.

His symptoms at present are, intense pain of the head, great heat of the scalp, watchfulness, agitation, vacant amaurotic stare, with dilated pupils, and numbness of the right arm, approaching to paralysis. Pulse 50, regular, but weak; tongue rather furred; appetite bad; skin cool; bowels regular; urine natural, and in proper quantity. Indeed it is only of the pain of the head that he complains. He answers questions rationally, though the other patients state that he is occasionally delirious.

The treatment at this time employed by Dr. Recamier was very simple. It consisted in the constant application of cold to the head, by means of a tube communicating with a tub of cold water placed just above his head; the exhibition of purgatives, when necessary, and in keeping him on low diet. These means have not the effect of relieving his intense sufferings, though the sensation of cold, from the constant application of a stream of water to his head, is very agreeable to him.

I watched this case very attentively for a considerable time, but no improvement took place, at least with regard to the affection of his eyes. The pain of the head did, indeed, occasionally abate, but only for short times together. He grew exceedingly emaciated, and, finally, decided symptoms of mental derangement ensued, in which state I lost sight of him, as he left the hospital.

Observations.—Here we have a case of amaurosis which was decidedly produced by congestion of the brain, causing paralysis of that part of the brain from which the optic nerve takes its origin, the exciting cause being a fit of passion; the predisposing cause his sanguineous and plethoric temperament, apparently not hereditary, as he informed me that his parents were healthy old people. The congestion appears to have been of that form which is described by M. Andral as the "first variety of cerebral con-

gestion,"* in his lectures now publishing in THE LANCET (and from the publication of which I became one of your subscribers; feeling greatly obliged for them, knowing, from personal experience, the value of the oral instructions of M. Andral). M. Andral there states, in speaking of cerebral congestion, "that it is attended with pain in the head, sometimes carried to a great extent, with vertigo, singing in the ears, giddiness, and, momentary aberration, or loss of sight, &c." And again, in another part, he says, "in some cases of cerebral hyperemia the symptoms may continue, with little or no intermission, for several months, or even for a whole year." Now in H. Forester's case the congestion apparently continued unremittingly for seven months, and it may have continued a much longer time, but as he then left the hospital I had not an opportunity of hearing any thing more about him. This case also well illustrates what Dr. ABERCROMBIE states in his excellent work, when speaking of the symptoms of different affections of the brain. He refers these symptoms to seven classes.† This case comes under the second form, or that of "headache, with affections of the senses." I will quote what he says: "After some continuance of fixed headache, the organs of sense become affected, as sight, hearing, taste, smell, and, occasionally, the intellect. The loss of sight generally takes place gradually, being first obscured, and, after some time, lost."

Numerous cases are recorded somewhat analogous to that of H. Forester, but none where a *fit of passion* is supposed to be an exciting cause of the disease. Dr. Copland, however, in his valuable "Dictionary of Practical Medicine," in his article "Amaurosis," mentions, in speaking of the different species of this affection, "*Amaurosis from Active Congestion* :—The existence of this species is more a matter of inference than is any of those into which I have divided the disease. Yet it seems undoubtedly to exist, especially when amaurosis is consequent upon obstructed secretions and discharges, or the drying up of eruptions; upon frequent stooping, or wearing a tight neckcloth, and upon *fits of passion*, when it occurs in plethoric persons."

CASE OF COMPLETE ABSENCE OF THE UTERUS.

A FEMALE, forty-six years of age, who had never enjoyed good health, and was of weakly constitution, had arrived at the age just mentioned without having once men-

struated. At the period of puberty the body and mammae were well formed; but the menstrual discharge was replaced by a constant pricking pain in the left hypochondriac region, occasionally shooting down to the pelvis. The exacerbations of the pain were accompanied with vomiting, and occurred generally every month, but not regularly. In the twenty-sixth year of her age, for the first time, a slight discharge of blood took place from the vagina, the patient being affected with acute fever. At the age of forty-six she was compelled to have recourse to medical advice, from an increase of pain in the left hypochondrium. The symptoms were dissipated by antiphlogistic measures. The woman now permitted an examination of the genital organs; the external parts were in a normal state, but the vagina, which was about one inch in length, terminated in a cul de sac. In the course of a year this patient died of peritonitis; and, on examining the body, Dr. ALBERS found the internal genital organs in the following state: The vagina, as already said, terminated in a cul de sac. About one inch and a half from it, and placed laterally, were found two bodies not larger than a good-sized walnut; these were oblong in shape, and did not seem to have any connection with the vagina; however, each of them sent off, upwards and sideways, a distinct bundle of fibres, terminating in the vicinity of another body, which appeared to be the imperfectly-developed ovary. Each of the oblong bodies, which we must consider as the rudimentary elements of the uterus, contained a small cavity, lined with a membrane analogous to mucous membrane. The tissue of the parietes, not more than two lines thick, was soft and fibrous. It was not easy to distinguish it from the round and broad ligaments, as all the parts together were enveloped in a mass of cellular tissue.—*Albers's Repertorium*, 9 year, July. Published September 24, 1835.

* See THE Medical Society of Toulouse was lately occupied with the case of a woman in whom also probably the uterus was wanting. The vagina here terminated in a cul de sac; the patient had never menstruated, and external examination could discover no trace of a uterus. Dr. HORNFIELD, of Berlin, has treated a similar case. The female, twenty-five years of age, had never menstruated. This was attributed to obstruction of the vagina. An operation was performed with the object of establishing communication between the vagina and uterus, but without success.

CASE OF
ARTIFICIAL ANUS,

PRODUCED BY A LANCE WOUND,
CURED AFTER A NEW METHOD.

Related by *Professor DIEFFENBACH, Berlin.*

A POLISH officer received, in combat, a thrust of a lance in the abdomen: the blade penetrated up to the shaft. The result was a wound about an inch broad and two inches from the umbilicus, from which blood and excrementitious matter were simultaneously discharged. The patient's life was saved by an antiphlogistic treatment, but an artificial anus remained, which resisted the means used by several surgeons to close it. The whole circumference of the opening was surrounded with a hard cicatrized mass, whose long diameter was five inches, and its breadth two inches. The middle of this mass was occupied by a round hole, which easily received the tip of the middle finger: its inner edge was lined with the mucous membrane of the intestinal canal; probably the transverse colon. An examination of the cavity of the intestine showed not only that it was united to the abdominal parietes, but that its caliber was considerably diminished. As soon as the opening was uncovered the contents of the intestinal canal issued forth; while it was compressed with a pelotte and bandage they were retained. However, when the patient went to stool it was impossible to prevent a discharge of fecal matter through the artificial anus. After various unsuccessful attempts, the patient had recourse to a celebrated physician at Berlin, who thought he could close the opening by a *silk diet*, restricting the use of all solid food. The treatment had no other effect than that of rendering the patient exceedingly thin. He now placed himself under the care of M. CASPER and the author. The first cure of the latter surgeon was to restore the patient's strength by proper diet &c. They then attempted to destroy the hard edges of the orifice with the actual cautery, but this means was also unavailing: an ill looking, pale, granular mass constantly shot up, which they could not get rid of. M. DIEFFENBACH now determined on endeavouring to close the artificial anus with a portion of integument taken from the sound parts; for this purpose he commenced by cutting away the hardened edge of the orifice, and then made a transverse incision of the abdominal wall, one and a half inches long, above the wound, and a flap of skin, two inches broad, was dissected off, and this was used to form a bridge that was connected by the integuments only with the integuments of the abdomen. After

having arrested the hemorrhage, M. DIEFFENBACH turned this flap downwards over the artificial opening, and united its edge with the lower edge of the circumference of the round cavity: here the two edges were united by a great number of small needles and sutures. The large wound thus produced was filled with charpie, to diminish the dragging and extension of the stitches. However, this experiment failed, the flap of skin died, and the granulations which sprung up were not sufficient to close the opening: the latter remained, although somewhat diminished. The author now proposed a method of treatment quite different; this consisted in destroying, with the actual cautery, the edge of the bowel united to the orifice of the wound, and also, at the same time, a considerable portion of the intestine within the orifice, sparing however, at each cauterization, the external integument. The edge of the intestine was touched with the actual cautery the first day: a few days later he introduced a hot iron, crotchet-shaped, and as thick as a pen, into the intestinal cavity, and touched its parietes all round. This gave little or no pain, and was followed with a happy result. The opening was immediately reduced by the rapid growth of granulations; and finally, after a treatment of nine months, the fistula was completely closed.—*Kleiner's Repertorium*, November 6, 1835.

CASE IN WHICH THE
OESOPHAGUS WAS INTERRUPTED IN
ITS MIDDLE PORTION.

The Superior Moity terminating in a Cul de Sac; the Inferior Opening into the Trachea.
—Observed at the *Hopital des Enfants Trouves, Paris.* By M. PADIEU, Interne.

A CHILD of the female sex, one day old, was brought and deposited in the "creche" of the hospital, on the 6th of August, 1835. Immediately after its reception the infant was seized with frequent vomiting: she threw up a sufficient quantity of bloody mucus to induce the nurse to say the child vomited blood. On the 7th the vomiting continued. The matter ejected consisted in a very spurious mucus, tinged of a red colour from the blood. The colour of the skin was slightly jaundiced. On the 8th, some vomiting; the integuments are cold; the pulse excessively small; the respiration embarrassed; face a little bluish; the drink taken into the mouth was rejected very soon after having been swallowed. Death on the 8th.

Body examined on the 9th.

Body well formed externally; strong; length 18½ inches. The brain and its membranes healthy. The lungs were

gestion,"* in his lectures now publishing in THE LANCET (and from the publication of which I became one of your subscribers; feeling greatly obliged for them, knowing, from personal experience, the value of the oral instructions of M. Andral). M. Andral there states, in speaking of cerebral congestion, "that it is attended with pain in the head, sometimes carried to a great extent, with vertigo, singing in the ears, giddiness, and, momentary aberration, or loss of sight, &c." And again, in another part, he says, "in some cases of cerebral hyperemia the symptoms may continue, with little or no intermission, for several months, or even for a whole year." Now in H. Forester's case the congestion apparently continued unremittingly for seven months, and it may have continued a much longer time, but as he then left the hospital I had not an opportunity of hearing any thing more about him. This case also well illustrates what Dr. ABERCROMBIE states in his excellent work, when speaking of the symptoms of different affections of the brain. CASE OF

ARTIFICIAL ANUS,

PRODUCED BY A LANCE WOUND,

CURED AFTER A NEW METHOD.

Related by Professor DIEFFENBACH, Berlin.

A Polish officer received, in combat, a thrust of a lance in the abdomen: the blade penetrated up to the shaft. The result was a wound about an inch broad and two inches from the umbilicus, from which blood and excrementitious matter were simultaneously discharged. The patient's life was saved by an antiphlogistic treatment, but an artificial anus remained, which resisted the means used by several surgeons to close it. The whole circumference of the opening was surrounded with a hard cicatrized mass, whose long diameter was five inches, and its breadth two inches. The middle of this mass was occupied by a round hole, which easily received the tip of the middle finger: its inner edge was lined with the mucous membrane of the intestinal canal; probably the transverse colon. An examination of the cavity of the intestine showed not only that it was united to the abdominal parietes, but that its caliber was considerably diminished. As soon as the opening was uncovered the contents of the intestinal canal issued forth; while it was compressed with a pelotte and bandage they were retained. However, when the patient went to stool, it was impossible to prevent a discharge of fecal matter through the artificial anus. After various unsuccessful attempts, the patient had recourse to a celebrated physician at Berlin, who thought he could close the opening by a *milk diet*, restricting the use of all solid food. The treatment had no other effect than that of rendering the patient exceedingly thin. He now placed himself under the care of M. CASPER and the author. The first care of the latter surgeon was to restore the patient's strength by proper diet &c. They then attempted to destroy the hard edges of the orifice with the actual cautery, but this means was also unavailing: an ill looking, pale, granular mass constantly shot up, which they could not get rid of. M. DIEFFENBACH now determined on endeavouring to close the artificial anus with a portion of integument taken from the sound parts; for this purpose he commenced by cutting away the hardened edge of the orifice, and then made a transverse laceration of the integument, three lines long, above the wound, and three lines long below it: a flap of skin, two lines broad, was dissected off, and this formed a new integument that was connected by its own extremities only with the integument of the abdomen. After

having arrested the hemorrhage, M. DIEFFENBACH turned this flap downwards over the artificial opening, and united its edge with the lower edge of the circumference of the round cavity: here the two edges were united by a great number of small needles and sutures. The large wound thus produced was filled with charpie, to diminish the dragging and extension of the stitches. However, this experiment failed, the flap of skin died, and the granulations which sprung up were not sufficient to close the opening: the latter remained, although somewhat diminished. The author now proposed a method of treatment quite different; this consisted in destroying, with the actual cautery, the edge of the bowel united to the orifice of the wound, and also, at the same time, a considerable portion of the intestine within the orifice, sparing however, at each cauterization, the external integument. The edge of the intestine was touched with the actual cautery the first day: a few days later he introduced a hot iron, crotchet-shaped, and as thick as a pen, into the intestinal cavity, and touched its parietes all round. This gave little or no pain, and was followed with a happy result. The opening was immediately reduced by the rapid growth of granulations; and finally, after a treatment of nine months, the fistula was completely closed.—*Kleinert's Repertorium*, November 6, 1835.

CASE IN WHICH THE

OESOPHAGUS WAS INTERRUPTED IN ITS MIDDLE PORTION.

The Superior Moiety terminating in a Cul de Sac, the Inferior Opening into the Trachea.
—Observed at the *Hopital des Enfants Trouves*, Paris. By M. PADIEU, Interne.

A CHILD of the female sex, one day old, was brought and deposited in the "creche" of the hospital, on the 6th of August, 1835. Immediately after its reception the infant was seized with frequent vomiting: she threw up a sufficient quantity of bloody mucus to induce the nurse to say the child vomited blood. On the 7th the vomiting continued. The matter ejected consisted in a very spurious mucus, tinged of a red colour from the blood. The colour of the skin was slightly jaundiced. On the 8th, some vomiting; the integuments are cold; the pulse excessively small; the respiration embarrassed; face a little bluish; the drink taken into the mouth was rejected very soon after having been swallowed. Death on the 8th.

Body examined on the 9th.

Body well formed externally; strong; length 18½ inches. The brain and its membranes healthy. The larynx, trachea, and

bronchi, examined in situ, do not present any thing irregular. The lining membrane of the larynx and trachea appears only a little more red than natural. The heart is not voluminous; the foramen ovale is greatly developed and open.

Intestinal Canal.—The pharynx and inferior moiety of the œsophagus are healthy; the stomach is very small; its parietes are in contact with one another; the cavity contains nothing but some mucosity mixed with a brownish-coloured matter. The mucous membrane is healthy; the small intestine is imperfectly developed, and its cavity scarcely admits the blade of a common-sized scissor. The large intestine is also reduced in diameter; but the descending colon and the sigmoid flexure are more dilated; they contain a considerable quantity of mæconium. On examining the trachea a second time, it was found that a small opening, of an oblong form, easily dilatable, and closed by the puckering of the tissues which surrounded, existed at the bifurcation of the bronchi. This was the orifice of a musculo-membranous tube which leads to the stomach. The superior moiety of the œsophagus terminated in a blind sac about an inch below the larynx, and was here united to the posterior wall of the trachea by condensed cellular tissue. The inferior moiety, ascended in its usual direction from the cardiac orifice of the stomach, passed along the right side of the aorta, and terminated, as we have said, in the inferior part of the trachea, near its bifurcation. This form of malformation appears to be unique. In all those hitherto observed, both extremities of the œsophagus, which is intersected for a greater or less extent, have terminated in a blind sac.—*Bulletin of the Anatomical Society of Paris*, 1835, No. 3.

TWO CASES IN WHICH THE CÆSAREAN OPERATION

WAS SUCCESSFULLY PERFORMED.

CASE 1. Related by Dr. WRETTER, army surgeon at Geldern.—A strong healthy peasant, who had been delivered by perforation of the child's head three years before, demanded on this occasion that the Cæsarean operation should be performed. The conjugate diameter of the pelvis was less than two inches. She felt distinctly the movements of the child; the labour-pains were very frequent and severe; the liquor amnii discharged; the os uteri moderately dilated. The head was the part which presented. The author, having bled the woman, and emptied the bladder with a catheter, made his incision along the linea alba. The loss of blood

was moderate, and the infant, with the placenta, easily extracted: the intestines did not protrude through the wound. After the operation the patient seemed well enough; but as the bowels were constipated, an Emula. c. sal. Glaub. et nitr. was given. She was also ordered a draught of the carbonate of soda, with some laural water and sirup of ipecacuanha. Finally, a lavement was thrown up. The bowels, however, remained obstinately costive. The patient vomited frequently, and was seized with constant hiccup and great anxiety and agitation. The abdomen appeared much developed between the umbilicus and false ribs; almost tympanitic; however, there were no absolute inflammatory symptoms. The patient was now ordered an inf. fol. sennæ compos., to be followed by an enema of Glauber salts with hyosciamus. This produced at first several feculent stools, and a discharge of flatus issued, succeeded by acute pain in the pelvis; at the same time the discharge of bloody serum from the inferior angle of the wound, left open on purpose, was much diminished. In order to prevent the passage of the secretion from the wound into the abdominal cavity, the woman was now placed on her abdomen, and a clyster of starch, with opium, was administered at once. The purging and painful sensations soon diminished, and the discharge from the wound took place with its former abundance. Centritization now rapidly advanced, the patient taking bark, calumba root, and wine, and on the seventh day after the operation the patient was able to leave her bed. The secretion of milk was small, and the infant was nourished artificially; however, it thrived well.

CASE 2. Related by surgeon Von der Fuhr, of Dulken.—The subject of this case was a female, thirty-six years of age. Labour had commenced twelve hours before the operation. This woman had already borne four children without any particular difficulty; but after her last delivery she commenced experiencing pains in the limbs, and especially in the region of the pelvis; these gradually increased to such a degree, that she was at last unable to move or walk. On examining the pelvis, it was found that the osæ pubis had inclined inwards towards each other in such a manner, that the arch of the pubis was completely gone, and the two bones formed an acute angle at the symphysis. The pronatory could be easily reached with the finger; the antero-posterior diameter was two inches and a quarter; the transverse diameter was two inches; especially the oblique ones. The diameter of the pelvis was smaller than natural. Under these circumstances, it was considered the only hope of mother and child lay in performing the Cæsarean operation.

This was accordingly done in the usual manner, and a healthy child extracted. After the operation the patient seemed more lively than could have been expected, but in a few days unfavourable symptoms set in, viz., frequent vomiting and constiveness. Some calomel, with an occasional enema, was administered; this brought away a quantity of feces and wind, and the patient felt much improved. The amelioration continued for the following days: the lochia now set in, and milk was secreted from the mammae; however, the wound did not present an appearance of speedy union; it was half open, and at the second dressing its edges were completely separated. The author, therefore, thought it best to heal by the second intention; the wound soon began to suppurate; every thing went on well, and it was healed in less than seven weeks. During this period the woman did not suffer from any of her former pains, and was carefully restored. The child died on the fifth week.—*Kleiner's Repertorium.*

DESCRIPTION

OF

THE ARTERIES

ENGAGED IN THE

ERECTION OF THE PENIS.

ANATOMISTS are not yet agreed on the mechanism of erection, nor in the manner in which the arteries of the corpora cavernosa penis are distributed in the interior of that tissue. The following is a resume of his researches lately made on this subject by Professor MÜLLER:—

M. MÜLLER distinguishes the arteries of the penis into two kinds, differing in their course, form, and termination. One set serves for the nutrition of the organ, the other are the vessels which determine erection. The *nutritious* artery (*arteria profunda penis*): passes to the spongy substance of the organ; its branches anastomose with each other, subdivide, become finer and finer, and, terminating in capillary vessels, are no longer to be followed by the eye. The *rectile* arteries (*arteria helicinae*) are very short and small, and are given off at a right angle from the larger and smaller branches of the *arteria profunda penis*; they enter into the cells of the spongy substance, and terminate either in a cul de sac, or by an *arterio-venous* expansion, without giving any further branches. The caliber of the *arteria profunda penis* therefore is formed, not only by the *nutritious* arteries, but also of the *rectile* arteries, which probably reside in the interior of the penis in flaccid state, on the other hand, during erection,

they conduct the blood into the cells of the corpus cavernosum. The *arteria helicinae* also exist in the corpus cavernosum urethrae (corpus spongiosum), and especially in its bulb; in front of this latter body they are not numerous; the professor has not discovered them in the venous cells of the glans penis. These erectile branches are most easily discovered in man; less so in animals, where they are very irregular.—See *Müller's Archiv. für Anatomie.*

HOPITAL DES ENFANS MALADES,
PARIS.RESEARCHES INTO THE DISEASES
OF CHILDREN.

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND
PATHOLOGY.

TUBERCULAR MENINGITIS.*

Child eight years of age; measles preceding; pulmonary consumption; death from acute hydrocephalus. Tubercular granulations in the pia mater of cerebrum and cerebellum; effusion into the ventricles; partial ramollissement of the brain; excavations in the lungs.

CASE 2.—Pauline Arnaud, eight years of age, of lymphatic temperament; with light hair; fine white satin skin; eyelashes exceedingly long, &c. Her father and mother are healthy; she has not been affected during infancy with any eruptions of the scalp, or glandular engorgements. At the age of seven she contracted the measles; the eruption went through its course with regularity, but left behind it some accidents, in particular a catarrhal affection of the bronchi, slight, however, and never forcing the patient to keep her bed. In the year following the attack of measles, the cough was moderately frequent; headache from time to time; never hæmoptysis or convulsions. On the 1st of August she was seized with malaise, vomiting, and a little fever. These symptoms persisted for three days. On the fourth she was admitted into the hospital.

Aug. 5. At the morning visit she presents the following appearances:—Embonpoint moderate; face a little flushed; decubitus dorsal; cough not frequent; expectoration none; little or no difficulty of respiration; heat of the skin moderate; pulse 108; respiration 24; the tongue is covered with a light whitish fur; the nausea and vomiting have disappeared; the abdomen is indolent and supple; the stools natural; no headache; the intellectual and sensorial faculties are intact.

Had the examination of the patient been

* We continue our series of cases of tubercular meningitis, from page 495.

confined to determining the above symptoms, we might naturally have considered her as convalescent from a slight gastric attack; but on practising percussion and auscultation we soon discovered the existence of grave disorders in the thoracic cavity. Under both clavicles percussion gave a dull sound. The stethoscope revealed the presence of gurgillement and pectoriloquy in the most decided manner; the inferior pulmonary lobes alone were permeable to air. The disease was at once diagnosed "pulmonary phthisis." A pectoral emulsion was ordered, and the patient allowed to take some solid aliment, as the digestive passages were in a good condition.

During the following days auscultation and percussion furnished the same signs as before, and confirmed the diagnosis. No change took place in the patient's condition until the 19th Aug. At this period diarrhoea set in, accompanied by an access of fever every evening, and terminating during the night in abundant sweats. The alvine flux was very obstinate, and resisted the employment of enemata with starch and narcotics.

On the 26th. The patient appears very dull, she refuses every kind of aliment. She answers the questions addressed to her with impatience. She avoids the light, and buries herself constantly under the bed-clothes. The pulse, however, remains calm. In the morning it gives only 84 pulsations. The respiration however is a little more accelerated; it is now 36. The abdomen is slightly tense, and painful to pressure; the chest is free from all kind of uneasiness; the patient complains rather of her head; no convulsive movement has been observed.

29. Profound alteration of the visage; alternating redness and paleness of the face; intense headache, forcing acute cries from the patient; vomiting. *Sinapisms to the lower extremities.* In the evening, convulsive movements of the muscles of the face and eyes; delirium; acute cries at intervals.

30. Deep prostration and stupor; pupils dilated and oscillant; complete loss of the vision; conjunctivæ injected; irregular movements of the globe of the eye; permanent rigidity of the muscles of the neck and trunk; resolution of the limbs; the sensibility of the skin is much diminished, especially on the right side; no trismus; no difficulty of deglutition; face is pale; abdomen supple; diarrhoea persists; five or six involuntary evacuations in the twenty-four hours; skin dry and warm, is covered with sudamina over the front of the abdomen and chest; pulse 144, small and frequent; respiration 40, and unequal; no cough or expectoration. *Blister to the neck; sinapisms to the lower extremities.*

31. The patient's eyes still agitated by convulsive movements. She murmurs every now and then some inarticulate words, without meaning or connection. The face is

flushed; the rigidity of the muscles of the trunk still very well marked. It is impossible to place the child sitting up in bed. She is lifted up as if made of a single bit. The sensibility of the skin still obtuse at both sides of the body. The limbs are in a state of resolution, except the right arm, which is contracted.

Sept. 1. The symptoms continue to present the same character. The patient now lies in a state of complete coma. All the senses seem abolished except that of hearing. Twice we addressed a question to the little patient in a very loud voice, and twice she made a movement as if terrified.

2. Coma more profound. When the eyelids, which had hitherto remained half open, but now are closed, are drawn asunder, the pupils appear a little contracted; the conjunctivæ are injected, and seem ecchymosed in some points; the cornea is dull; its surface covered with an albuminous exudation. The movements of the globe of the eye are less pronounced than formerly. Persistence of contraction of the right arm, and of the tetanic rigidity of the neck and trunk. Pulse excessively accelerated, filiform; evacuations are involuntary; death at eight o'clock in the evening.

Body Examined 37 Hours after Death.

External Appearance.—Body but little emaciated; no cadaveric rigidity; anterior parietes of the abdomen present a greenish tint.

Cavity of Skull and Rachis.—Skull well formed; dura mater healthy; the glandule pæchioni seem small in number. Underneath the arachnoid which lines the convex surface of the hemispheres, exists a great number of granulations of a whitish-yellow colour, and varying in size from a millet-seed to a large pin head. They are more numerous on the left side than on the right, and are chiefly confluent on the middle and external portion of the left hemisphere, and at the base, in the fissure of Sylvius. On the anterior and external surface of the left hemisphere, they are multiplied to such a degree as to produce small yellowish spots adhering on one side to the arachnoid, on the other to the substance of the gray matter forming the convolutions; the latter is softened with injection of its substance to the extent of an inch square, and to the depth of two or three lines; each lateral ventricle contains about three ounces of serum. The fornix and anterior walls of the ventricles are softened, but without any change of color. No alteration in the rest of the cerebral mass; an abscess. The pia mater covering the surface of the organ and of the pons varii is healthy. The fibrous and serous membranes of the spinal marrow are softened; a considerable

able quantity of serous effusion, but the chord itself is perfectly normal.

Chest.—Adherence of both lungs to the costal pleura. Each of the two superior lobes is occupied by a large empty anfractuous cavern. The other lobes are healthy; we do not find in them any tubercles, either isolated or en masse. The larynx, trachea, and bronchi, do not present anything remarkable. The bronchial glands are hypertrophied, but have not undergone the tubercular degeneration; heart and pericardium healthy.

Abdomen.—Peritoneum free from alteration; mammellonnated appearance and slight injection of the mucous membrane over the great cul de sac of the stomach; the rest of the membrane is of a rosy gray colour, and does not offer any change of consistence. The mucous membrane of the small intestines is, generally speaking, pale; it presents some points of ulceration near the end of the ileum. Some of the mesenteric ganglia are tubercular. Numerous ulcerations exist in the cæcum and in the colon; around the edges we detect a remnant of tubercular matter. The consistence of the mucous membrane of the great intestine is throughout diminished; the liver has undergone the fatty degeneration; the other viscera are sound.

P. H. GREEN.

LATE ELECTION

AT THE

RICHMOND HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

SIR,—Knowing that the pages of your invaluable journal perform at once the duplex functions of exposing medical abuses and suggesting practical remedies for their correction, may I, therefore, beg your attention to the subjoined statement of facts, which have produced much talk, if not excitement, amongst the politico-medical circles in this city, during the last fortnight or three weeks.

Mr. M'Dowell, a gentleman of much intelligence and indefatigable industry, who held the important office of Surgeon to the *Richmond Hospital*, fell a victim on the 7th instant to an over-zeal in his professional pursuits, which unfortunately outlived the powers of an ardent mind and a delicate constitution. I will leave the melancholy task of writing the eulogy of this estimable man and excellent surgeon, to a more able pen than I can wield, and content myself for the present by declaring my profound and unfeigned regret, that by his premature and much lamented death, an invaluable and a most worthy colleague

solate family have experienced an irreparable loss, society has been deprived of one of its brightest ornaments, and the surgical profession in Ireland of one of its most distinguished and independent members.

I need scarcely inform you that Mr. M'Dowell's death created a vacancy in the Hospital in which he was so efficient an officer. An inconceivable number of candidates for the vacant situation suddenly appeared in the "contested field," each putting forward his qualifications and claims to the best of his judgment, either by letter, proxy, or in *propria persona*, to the members of the Irish Government, with whom this appointment rests. Mr. Cusack Roney, the *ex-surgeon*, who in prophetic talents, in matters of self-interest, rivals Pastorini, in this transaction anticipated the uncompromising hand of death, and in what he no doubt considered a clever hit, sought by a very early, if not an indelicate application, through his friend Mr. Moore O'Farrell, M.P. for Kildare, and one of the Lords of the Treasury, that situation, for an obscure relative, which was *as yet* the vested and legal right of the unfortunate sufferer, and for whose place, in excellence of character, it would be difficult to find a competent successor. Mr. White, of poor-law and cholera notoriety, employed as his advocate the eloquent Member for Tipperary, Mr. Sheil, who "could see no reason why his friend should not be appointed at once; he who had trodden the beaten path through the vale of years, and whose brow wore the indelible impress of the scathing hand of unsparring Time; in a word, he whose locks had not only grown gray, but had actually acquired an argentea brilliancy, in the cause of his country and suffering humanity." The Attorney-General, Mr. O'Loughlin, thought it would be no great compliment for the Government of which he is so distinguished a member, "to nominate his cousin, Mr. Kevin, who had been shamefully neglected, not only by former Governments, but by the public at large, for more than half a century." Mr. Trant's cause was ably advocated by his friend, Mr. Maurice O'Connell, the honourable Member for Tralee, who stated that he spoke the sentiments of his father.

This was an unfortunate mistake in the learned gentleman's address; for, when he had concluded his oration, Lord Morpeth, by way of reply, slyly drew from his pocket a letter which he had received from the Liberator himself, in which he strongly recommended to his Lordship's attention another person, Mr. Lynch, whose capability as a clinical lecturer is but too well known to the pupils of the *Jervis-street Infirmary*.

Mr. O'Reilly was escorted to the Castle by a Mr. O'Farrell, the M.P.'s brother, who introduced him to Lord Morpeth, as being "the most efficient surgeon that could be

All this was done before the public were apprized, by advertisement, or otherwise, that his *disinterested* predecessor had any intention whatever of resigning in favour of the luminary whom the contracting parties deemed a *suitable* successor.

So much for the practices of two of the faithful delegates. As to Mr. Carmichael's prowess as an intriguer, I don't think it necessary to add one word beyond what has been already stated—namely, that he has been *induced*, within the last few days, to resign a post of honour on conditions best known to himself. What could be more insulting to the candidates, all of whom were legally qualified to fill the situation, and whose names were forwarded to the commissioners, than to pass them by, and nominate one of their own creation, assigning as their reason for so doing the unblushing falsehood that it was necessary that Mr. Adams should be appointed to preserve the respectability of the "medical school of Dublin?" This is not only an insult to the medical teachers of Dublin, but a false representation in which the commissioners betrayed their trust to the Government which gave them power. Why, Mr. Adams and the *learned* commissioners would not be missed out of the medical teachers of Dublin, even if it were ordained by Providence that they should forthwith be translated "to another and a better world." However, let us now, for argument's sake, suppose Mr. Adams's exertions in the cause of the rising medical generation were ten times more efficient than they ever have been, and inquire how could the sphere of his usefulness be extended by his recent appointment to the *Richmond Hospital*? In no one way. Yes, Sir, I repeat it, in no one way can his new appointment render Mr. Adams's services more useful to his pupils, or "the medical school of Dublin," than they were before. Mr. Adams was attached as lecturer to a school which afforded him ample opportunity of imparting information to his pupils; he was likewise one of the surgeons to the *Jervis Street Infirmary*, and had there abundant scope for giving clinical instruction to the pupils of that institution. Now, I beg leave most respectfully to ask the commissioners, Messrs. Crampton, Colles, and Carmichael, to justify themselves in the line of conduct they were pleased to pursue in the exercise of their high judicial authority, in treating with *contempt* the gentlemen whose names were inscribed on the list which was sent to them by *unscrupulous*, and in this instance a too *unscrupulous* Government? I must in candour confess it was a matter of great surprise to me to find that there is no person more *unscrupulous* than Mr. Adams himself, that he, *unscrupulous*, and the particular friend, *unscrupulous*, of the late Attorney-General Blackstone, should find himself the

chosen protégé of a reform Government! I doubt if a greater enemy to reform, or a more strenuous supporter of Toryism, could possibly be found in the medical profession than Mr. Adams. As a proof of the truth of this statement, I beg to apprise you that during Lord Haddington's ephemeral administration in this country, Mr. Adams was, *on principle*, appointed to a lucrative Government situation.

When I state these incontrovertible facts regarding Mr. Adams, I do not wish to be understood as speaking disparagingly of him either as a surgeon or a gentleman. On the contrary, I believe he possesses a fair share of professional information, and that he is an honourable man. However, when I express myself thus, I wish it to be distinctly understood that the conviction on my mind is, that he owes his present appointment more to the religious and political prejudices of the commissioners than to his scientific attainments or private worth. I should be sorry to say that Mr. Adams ought to be classed with such rancorous bigots, both in religion and politics, as Messrs. Harrison, Jacob, *et hoc genus omne*, who take a pride in declaring, on all *suitable* occasions, their uncompromising hostility to the *present* Government, and their unextinguishable hatred to every thing liberal. By the way I have just heard that the voracious Mr. Harrison wished to become a candidate for the *Richmond Hospital*, and so far succeeded in imposing himself as a *liberal* on the able and learned Member for Wexford, Mr. Walker, that Mr. W. actually exerted his influence in favour of this political cheat with the Irish Government. Oh, shame, where is thy blush!

Well, Sir, we are told that "out of evil cometh good." Such being an acknowledged truth, the friends of reform and fair play could not possibly wish for a stronger case in favour of the necessity of legislative interference, as regards medical appointments in Great Britain and Ireland, than the one I have laid before you and the readers of your journal. Had the system of election by concursus been in operation in the present instance, the Government would not have been driven by the humiliating act of a mistaken expediency, to the appointment of an *improper* Board of Commissioners, nor could they be taunted with having conferred power and place on *their* political enemies, to the unjust exclusion of their own supporters!

I have only one observation more to add on this important subject. It is simply this, to express a hope that the names of the ex-commissioners, CRAMPTON, COLLES, and CARMICHAEL, will be distinctly remembered, both by Mr. Warburton and the Government, should the promised Medical-Reform Bill lead to the establishment of a central board in Dublin, as persons who have, by their recent conduct, completely

commenced, I was not acquainted with the nature of the resolutions passed, until the next meeting, when I read them, and objected most decidedly to the third, which ran as follows:—"The meeting pledge themselves individually not to enter into any contract with the Guardians of the Poor, for the whole or any district of a union, without the concurrence of Messrs. Way, West, and Starling." By this resolution the Committee had so arranged matters, that no one should, consistently with his honour, have anything to do with the parishes, excepting such portions of them as they, presuming upon their appointment, might be disposed to give up, being either at too great a distance, or not worthy of their notice.

When Mr. Way called upon and pressed me to attach my signature to the resolutions, which I had returned without signing, I objected to do so on the score of the third resolution, and was then told by Mr. W. (one of the Committee), that the consequences of my refusal would be exclusion from all future medical meetings, and that should I at any time require assistance in any case of emergency, it would be denied me by all the medical men in the place and neighbourhood.

It is further stated in a resolution passed on the 26th of November,—"That the meeting express their deep sense of the apparent injustice which the Board of Guardians of the Tunbridge Union have committed in appointing a gentleman who had been less than four months in the district, to the charge of the sick poor of four parishes, which have hitherto for many years had the attention of five of the oldest practitioners in the place and neighbourhood, who were willing, if required, to continue their services on the proposed terms." * * * In reply to this, I beg to say, that although I have resided in the district only four months, I have, nevertheless, lived several years as assistant to one of the first practitioners, and in that situation have had the care of a part of the district. If the meeting meant,—when they said, in their resolution of Nov. 26th, that the district had been formerly under the care of the *oldest* practitioners,—to convey the idea that the poor cannot be so well attended by the *junior* practitioners, I beg to remind them that the pauper poor have been hitherto attended by the assistants, and even apprentices, of some of those old practitioners; and there exists a minute in one of the *parish books*, complaining in no measured terms of the inefficient treatment which one of them at that time received from us.

I beg to add that I have attended the parishes, but have given my help to a practitioner in the place, and such arrangements have been made as shall

secure to the poor prompt attendance, and, in all cases of emergency, the attention of two *principals*, an advantage which they have never before enjoyed. I have the honour to be, Sir, yours very obediently,

HENRY L. SORWITH.

7, Mount Pleasant-terrace, Tunbridge Wells,
December 23rd, 1833.

* * * To prevent a long and fruitless controversy on matters in which Mr. Sorwith himself has not been placed in the situation of defendant, we have withheld from publication some passages in his letter. They relate to questions which are not really involved in the points at issue between Mr. Sorwith and the deputation.

THE CERTIFICATE SYSTEM.

To the Editor of THE LANCET.

SIR,—As I perceive from the letter at page 316 of THE LANCET, signed "A STUDENT," that the writer is willing to end the controversy, I shall, to prove myself actuated by a like spirit, forbear replying to many of his assertions, and shall content myself with laying before the public the following extract from a lecture delivered by Dr Elliotson, at the London University, being the first he ever delivered at that institution, and containing a most excellent programme of what a medical education should be. I myself was a much-pleased auditor, but any of your readers who have not read it, may find it at page 64 of the volume of THE LANCET in course of publication in October 1831. The extract is as follows:—

"The mode of instruction by lectures, though by no means sufficient of itself, is in my mind of high importance. When a whole subject can be taught in a solitary course of lectures, and the exhibition of nothing is required, so that a mere delivery of statement constitutes the whole task of the professor, there can be no doubt that a good work containing all the same information might be studied in private with equal benefit, and indeed with this advantage, that it would, after probably costing less, remain in the possession of the student, to be consulted by him whenever he thinks fit. But when a circle of instruction is required, when the subjects are numerous, and demand many courses of lectures and many professors, the student cannot be committed to himself. Without lectures he would become almost to a certainty bewildered, study at irregular intervals, and wander from one subject to another, gathering little fruit from any. Whereas the attendance on various lectures at stated hours creates an excitement and interest, as well as a regularity of habit, which are of incalculable utility."

Such are the opinions of Dr. Elliotson on this much-disputed point, and as he is one of the most talented members of the medical-reform party, these arguments, strengthened by the authority of his name, will go much farther towards producing conviction, than any I could adduce. I therefore for the present bid farewell to this subject, which I have not undertaken without pondering well over the following lines from Horace's book "De Arte Poetica :—"

"Sumite materiam vestris, qui scribitis egnam
Viribus; et versate diu, quid ferre recuset,
Quid valeant hauriri. Cui lecta potenter exit res,
Nec facundia, deserit hunc, nec lucidas ordo."

That I was not inadequate to the office I undertook, is, I hope apparent to all. I have endeavoured to treat upon the subject with all possible calmness and moderation, and in retiring from the field of controversy, allow me to thank you for your liberality in allotting so much space to the writings of a political opponent. I remain, Sir, your obedient servant,

A KING'S COLLEGE STUDENT
OF MEDICINE AND SURGERY.
December 29th, 1835.

. Our correspondent commits a great error in quoting the opinion of any lecturer in favour of attendance on lectures, and on the propriety of rendering that attendance imperative on students. The question, however, is not whether certain courses of lectures may be advantageously attended or not, but whether the student shall be compelled to pay for certificates of having attended those courses, and many others.

REDUCTION BY A TWIST.

To the Editor of THE LANCET.

SIR,—Although dislocated hips may generally require pulleys and pulling, yet the profession should know that they will sometimes "go in with a twist." Last evening I was quietly taking my infusion of green tea, when "our hospital man," as my waitress calls a certain personage, announced a dislocated hip taken into Guy's, adding that Mr. "Morgan was sent for." Knowing by dire experience that Mr. M. never hurries, I proceeded very deliberately to the scene of action. I found students assembled in the theatre, and a man in a gray frieze cloak, handling ropes, pulleys, &c. in the area. A small candle placed near him, mildly illumined his vivacious countenance, and cast a dim religious light on the spectacled and muffled men around. I eyed the pulleys, the gray man, the pany candle, the spectators, and the shadows in the back ground, until I shivered. From half to three quarters of an hour

however elapsed, the candle became dimmer, the shadows fewer, and at last the man in gray disappeared, when an ancient gentleman, with a broad-brimmed hat and broad-rimmed spectacles, entered the theatre and exclaimed, "Gentlemen! the dislocation is reduced. Mr. Morgan bids me say that he extended the limb, and it went in with a twist."

I descended to inspect the patient, and found him to be a man with a thigh like a life-guardsmen's, and a belly to match. "Lucky fellow!" thought I, as I entered the case in my book, "to have thy dislocation go in with a twist! Enlightened students, to get such a clear and copious clinic, by proxy, on the case!" Your obedient servant,
Mr. Editor, Q.
Dec. 24th.

The Dublin Journal of Medical and Chemical
Science, January 1836.

THE fund established during the recent summer for the support of Ireland's "only Journal," is not yet, it seems, exhausted. Another number has just come out, in which the causes of the expensive failure are still more manifest than on any former occasion. The communications called "original," by custom or by courtesy, we presume, are below the usual average of such contributions even in that Journal; the reviews exhibit the ordinary mixture of partisanship; and it is enough to say, with regard to the "politics" of the Journal, they are by Dr. Jacob. But what opportunities for observation, what records of disease, or what talent in its investigation, could bring into favour in Ireland a work which is notoriously designed to promote the local professional advantages of the party by whom it was instituted and is supported? The feelings of distrust, suspicion, and contempt, which the appearance of each number of this periodical excites in Ireland, render the work a most inept and uncongenial periodical for the circulation of scientific matter in the profession. Even had it the command of very numerous and able communications, which it certainly has not, its character as a means of promoting the personal interests and aggrandizement of a Junto, would ever narrow the sphere of its utility and influence.

In November we analysed the contents of the current number, and in about 100 pages of THE LANCET presented our remarks with every sentence pointed and intended to

passed through five pages of "original communications" in the Dublin miscellany. In the number of the work for January 1836, we literally find nothing to analyse. We have Dr. Jacob again upon the endless theme of the infra-orbital cavities in deers and antelopes. When his labours may terminate on this subject there is no possibility of stating, as they conclude upon this occasion with a mere conjecture that these cavities are intended for the secretion of a peculiar odoriferous matter, by which the animals that possess them are enabled to distinguish sex, or recognise species. In corroboration of this opinion he gives an analysis of a large solid mass of the indurated secretion of these cavities in the wapiti deer, conducted by Dr. Geoghegan, who describes this material as consisting of a "number of hairs, with a quantity of cuticular delicate flakes, the whole intimately mixed with a dark matter composed as follows: a brownish, viscid, oily substance, probably containing resin; a volatile odorous principle; extractive, soluble in water and in alcohol; colouring matter which adheres to the flakes of cuticle; lactates of soda and lime; a trace of phosphate of lime; and chloride of sodium in considerable quantity."

This paper is followed by three cases of malignant *Diphtheria* by Mr. BEWLEY. They are detailed with an attention to the record of unimportant particulars which bids defiance to analysis. It must therefore suffice to say that the subjects of this dangerous disease, and of Mr. Bewley's more than paternal care, were three sisters, aged, respectively, five, three and a half, and two years; and that notwithstanding a diversity of treatment adopted in the different cases, and the advantage of the opinions of several practitioners, the disease proved fatal in each instance. Mercury was extensively employed in these cases, and nitrate of silver was applied to the fauces, but without affording relief. Mr. Bewley also informs us that he proceeded to Dublin to have the advice of Dr. Graves, who, from the prescriptions in the report, recommended the chloride of soda, to be given internally, and applied to the fauces. The chloride seems to have produced no better effect than the other remedies employed. Mr. Bewley's observation is the capital to consult the "author" and remind the reader of the practice of those persons, who, in the "olden

times," went to some "Norna of the Fitful Head" to purchase a favourable wind; and the results in both cases are much the same, the "filtres" of the Dublin sage being no more serviceable than the "potions" of his country friend.

Whoever is curious to study a specimen of that kind of composition which generally prevails in the articles that are read at the tea and coffee meetings of colleges and halls, had better peruse attentively the "Observations on Diffuse Cellular Inflammation, with some Remarks on Contagion," of Dr. CHARLES LENDRICK, the next article in the number. It is a prim, pretty, pedantic production, which illustrates well the substitution of sound for the emanations of sense, wherein common-place announcements are rendered particularly original by the dexterous collocation of words and sentences. To the merit of such an achievement the author is certainly entitled, and we award to him the palm with the utmost readiness, but his reflections are by some years too late to secure him any further credit for the article, the facts and opinions out of which his paper is manufactured being as familiar to the profession as "household words."

A paper of a somewhat similar kind follows, by Mr. INGLEBY, Professor of Midwifery in the Birmingham School of Medicine, who nestles here after having wandered to and from almost every other medical periodical in the three kingdoms. His subject is, "Laceration of the Uterus and Vagina, with Cases." From whatever cause, it has been generally remarked, that professed writers on midwifery are the most prosing and tedious story-tellers under the sun. We do not consider the opinion universally applicable, but yet it is almost impossible not to suspect that the authors who treat of "obstetrics" become unconsciously infected with the garrulity of the sex upon whom they attend. Their prolixity, at least, is unquestionable. We remember Dr. Hamilton's lecturing for a whole week on the case of the Princess Charlotte, though four hundred miles separated the commentator from the subject of his criticisms during her illness. Mr. Ingleby's paper occupies twenty-seven pages of print, and is then cut off by the editor just at the point where it terminates as an introduction to some cases. He commences on as regular a plan of divi-

sion and subdivision, of heading and "briefing," his subject, as if he were about to favour the world with a cyclopædia of midwifery. Thus we have "Preliminary Remarks;" "The Frequency of these Injuries;" "At what Period of Pregnancy arising;" "Laceration usual in First Labours;" "The Reason of this Explained;" "Laceration considered under two Principal Heads;" "Subdivision of the First Head;" and so on through all the grades of division, distinction, difference, and definition, that imagination can conceive.

The next paper consists of a series of observations on Fractures, by Dr. Houston. It contains a number of cases successfully treated according to a plan respecting which Dr. H. claims credit for some degree of originality. In this conceit, however, he errs, for the plan which he describes with such insufferable minuteness, differs neither in principle, nor much in detail, from that which is in common use in Dublin and elsewhere. But the cases are creditably drawn up, and accompanied by some remarks on spasm of the muscles in fractures of the extremities, which may deserve attention. However, Mr. Radley, in recommending the abandonment of splints, showed that an important part of his plan consisted in the prevention, or in affording the means of the speedy allayment, of spasms of the muscles in cases of fracture of the long bones, as one result of the disuse of splints. Much of the labour of Dr. Houston is expended uselessly, therefore, if Mr. Radley's views and premises be well founded and correct.

Dr. Graves has discovered another form of disease for which his "sugar of lead" is a "sovereign remedy." The readers of the Journals are, of course, well aware of the specific virtues of this medicine in cholera, through the writings of Dr. Graves. One of the medical attendants of the cholera hospitals in Dublin put him on the scent of that valuable remedy in cholera, and Dr. Bardsley, it appears, performed a similar service for him on the present occasion. "I was first," he says, "led to use this medicine in considerable doses (the Doctor is an apostle of the heroic-dose school in the latter stages of protracted fever), on the recommendation of Dr. Bardsley, for the purpose of preventing that state of bowels which so insidiously leads to the ulceration of Peyer's glands. * * After-

wards analogy led me to apply it for the cure of tympanitis, combined with diarrhoea, in the middle or later stages of fever, and I have much reason to congratulate myself upon this new application of the remedy, for it has been very successful in my hands!" All medicines, indeed, possess this luck in the hands of Dr. Graves. Any agent of the Pharmacopœia that he may fortunately be "led to use" or patronise, *presto* becomes "successful." The great desideratum attained in the "flying island" will doubtless be achieved one of these days by the Doctor in the "extraction of sunbeams from cucumbers!"

New and Complete Manual of Auscultation and Percussion applied to the Diagnosis of Diseases. By M. A. RACIBORSKI, D.P.M. formerly Surgeon in the Polish Army &c. &c. &c. Translated by William Fitzherbert, B.A., Cantab. London: Bailey and Co., 1835. Pp. 204.

THE work of Dr. Raciborski has acquired great popularity in France, the birthplace of auscultation. In his preface, the author says, "The present publication is a *manual* on auscultation and percussion; that is, a portable book. All elementary books should be portable; not merely because the form is more convenient, but also because the domains of a science being once well determined, and reduced within proper limits, *those limits are always within bounds*!" We have ever considered that knowledge should be carried in the head, or remain in the library, and not occupy a place in the *portefol* of a medical man. Consequently, to "*vademecums*," and "*manuals*," we have usually shown ourselves to be inimical,—as inventions which are only designed to relieve the occasional embarrassments of ignorance. We do not therefore appreciate the value which our author sets upon the *portability* of his volume. Perfect knowledge of any branch of art can only be acquired by continuous study, and may as well be derived from a big book as a little one. The special charm of a "*manual*" is its *compactness* and its consequent *accessibility*. The *reality* of epitomes and *condensed* works is *grossly* imperfect, although *abridged* works of the *author* of the *now* before us, may *seem* a *very* *valuable*

Outline of the subject to which they are devoted, and in physical science, such as that of medicine, where much personal observation is implied, ~~such a compendium~~ may in its proper place prove an adequate substitute for a more voluminous work. Manuals may be correct, though they cannot be full. A scholar's globe may be perfectly accurate, though it can present but few details of the face of the earth, and the student will gain much knowledge of geography by its use. Indispensable qualities in an elementary work are, correctness of arrangement, clearness of principles, and strikingly illustrative details. We will try the volume before us by these tests.

The science of auscultation, on its first introduction into this kingdom, experienced the fate of all important discoveries. It was received with almost universal ridicule; but year after year the number of its disciples has increased, and, being dispersed throughout the various provinces of the empire, have propagated its doctrines so widely, that there are not now twenty men, — unless they be *pure* physicians and Fellows of the College, — who do not use the stethoscope in forming their diagnosis in supposed affections of the thoracic viscera.

In reply to the general demand for guides on this subject, almost the only work we have been able to mention with approbation, is the translation of Laennec's work by Dr. Forbes, the cost of which is expensive. There are many persons, therefore, who, without our attempting to draw for them a comparison between the two works, will be glad to meet with the translation made by Mr. Fitzherbert, who states that the chief merits of the volume consist in the new matter which it contains, and the clearness with which the author has arranged all that is yet known on auscultation and percussion. The author's preface we condemn, as full of erroneous dogmas. The translator should excise it in the next edition. The introduction forms an ingenious essay on the utility of auscultation and percussion. The work itself is divided into two parts—1. The explanation of different signs obtained by percussion and auscultation. The evidence afforded by these signs in the diagnosis of particular diseases. The first and second parts, fully and satisfactorily, permeate in all the regions of the thoracic cavity, and abdominal. The pro-

priety of this arrangement is obvious. A knowledge of the percussive responses in the healthy state, must precede a knowledge of their morbid deviations. Then comes a judicious essay on auscultation in general. In describing the normal respiratory sound, M. Raciborski controverts an opinion of Dr. Bean as to its physical causes:—

"The friction of the air against the parietes of the bronchi and vesicles, appears to us, as it did to Laennec, the simple cause of its formation. According to Dr. Bean, 'the noise of normal respiration is produced by the resonance, in the whole column of air inspired and respired, of the sound resulting from the pressure of this column against the soft palate and adjoining parts.' 'When the guttural noise is suspended,' says Dr. Bean, 'the tracheal and vesicular noises no longer exist, the respiration, although silent, takes place as usual, and if you did not feel under the ears the thoracic parietes retire and advance alternately, you might believe the individual did not breathe.' We object to this, that if there were no other signs of respiration but those afforded by the depression and elevation of the thorax, it is very probable that respiration did not take place, and that if it occurred without noise, it was because the air did not arrive in sufficient quantity, nor rapidly enough to produce it; and that the reasons for which the tracheal and vesicular sounds did not exist, are precisely those which would hinder the formation of the guttural sound. As to our own experience, it has furnished us with results directly contrary to those of Dr. Bean. Patients required to breathe on a sudden, and therefore making more noise in the trachea, have the respiration very slightly remarkable; on the other hand, the respiratory murmur, although feeble, has been distinctly heard in persons with whom the soft palate made no noise. But to meet with these cases, you must choose persons with whom the expansion of the lungs is habitually marked, or whose respiration is puerile. Although Dr. Bean pretends to have heard normal respiration, by blowing through a tube of paper against the soft palate of another person who held his breath, we have tried the same experiments several times, without producing analogous results. Most commonly we have heard nothing in the chest, but sometimes an echo of the noise produced in the throat; that echo, however, had no similarity to the murmur of respiration."

M. Raciborski's remarks on the auscultation of the respiration and the voice, tally with our own conclusions on the subject. We quote the following morceaux relating to the more interesting auscultative phenomena:—

"When a cavern bursts in the cavity of the pleura, this cavity contains a collection of liquids proceeding from the broken cavern, or afterwards secreted by the inflamed pleura. In this case auscultation will frequently detect in the chest, a particular noise, called by Laennec *tintement métallique*. The father of auscultation attributed the *tintement métallique* to the vibration of the air at the surface of the liquid, when the latter is agitated by the respiration, the voice, or coughing. Dance brings forward the following opinion with regard to the formation of this noise. When the level of the liquid, contained in the cavity of the pleura, is superior to the orifice of the cavern, the air which enters at each inspiration into the lungs, rushes into the cavity of the pleura, rises through the liquid in the shape of a bubble, by reason of its specific gravity being less, and arrives at the surface, where the bubble breaks, and produces the *tintement métallique*."

This observation had passed unnoticed. It is only lately that Dr. Bean, without being aware of the coincidence, happened to suggest the same idea, which he explained and verified by numerous experiments.

"The *tintement métallique*, for which Dr. Bean has substituted the term *tintement bullaire*, may, according to that writer, be equally well heard during expiration, coughing, talking, and expectoration. In fact, he observes, although in these acts the air be expired instead of inspired, still in the majority of cases of the presence of caverns, the surrounding part of the lungs is hardened, and does not collapse during expiration, the air expelled from the rest of the lungs rushes from the trachea into the open bronchi, and from thence acts as air inspired. Most generally this noise follows each act of respiration; sometimes, however, it takes place slowly, which seems to arise from the circumstance, that the bubbles before bursting may stop some time at the surface of the liquid.

"According to Dr. Bean, the same noise is sometimes heard in large caverns, filled in a great measure with liquid, and in hydro-pneumothorax, without any communication with the respiratory passages. But in these two circumstances, it is difficult to conceive the formation and rupture of bubbles, and we must admit, in certain cases of *tintement métallique*, the simple explanation of this sound given by Laennec in the case when it accompanies the rupture of caverns into the cavity of the pleura.

"It happens frequently with patients in these conditions, that when they change a horizontal for an upright posture, drops of liquid, adhering to the pleura, or retained by false membranes, become separated from the mass of liquid, which falls to the inferior part

of the cavity. These drops, by falling upon the surface of the liquid, occasion a noise analogous (similar) to that produced by the fall of a drop of water in a decanter containing a certain quantity of liquid. This is a variety of the *tintement métallique*."

"The cases in which the *tintement métallique* is observed, present another phenomenon. Whenever the cavity of the pleura, or a large cavern in the lungs, contains liquids and gases, you will hear, when you shake the thorax, the fluctuation of the liquid; this is called by Hippocrates *succussion*, and since his time, has been known as Hippocratic succussion. You may imitate this phenomenon by shaking a decanter containing a small quantity of liquid."—pp. 82, 83, 84.

The following paragraphs relate to the abnormal resonance of the voice through the parietes of the chest.

"The resonance of the voice is very distinct in the regions where the bronchi are superficial, but less so in those regions which correspond to laminæ of vesicles, on account of the numerous divisions experienced by the undulations of sound in arriving at the extreme ramifications of the bronchi.

"1. Hence, if the cavities of the vesicles be destroyed by any cause whatever, the voice will resound in the bronchi corresponding to the obliterated vesicles, and that in proportion to the greater or less extent of the obliteration. This abnormal resonance of the voice through the parietes of the chest, is called *voix bronchique* or *bronchophonie*. The impenetrability of the cavities of the vesicles, whether it result from the presence of tubercles, or from the concretion of the sero-sanguineous matter secreted by the parietes of the vesicles in the second stage of pneumonia, will therefore occasion this phenomenon.

"2. The same phenomenon is observable when the impenetrability of the vesicles is produced by an effusion in the cavity of the pleura. But if in this case the liquid be in too small a quantity to compress entirely the lamina of vesicles, and only causes a closer application of the pleura to the parietes of the vesicles, so as to form therewith a membrane more or less tense, applied to the extremities of the respiratory passages, the resonance of the voice will, in this case, offer a very remarkable character. It is a broken interrupted sound, like the voice of a person who stutters. It has been compared to the plaint of a goat, whence its name of *tyophonie*.

"According to certain recent writers, *tyophonie* is an uncertain sound, certainly not always easy to recognize, but with attention and practice it may be distinguished from other signs.

"When the respiratory passages are dilated over a more or less extensive portion,

as the case in partial dilatation of a bronchus, or in an excavation of the lungs, consequent upon tubercles, the resonance of the voice in those parts is such, that the patient seems to talk in the ear of the examiner, especially if the latter auscultate with the stethoscope. This is *pectoriloquie*, which is complete when the cavern is superficial, and adheres by its sides to the costal pleura, and when its angles are indurated; but it will be more diffuse, and may be heard over several different points of the chest, when it indicates a considerable dilatation of the bronchi. The hand applied over the parietes of the thorax during *bronchophonie*, feels the *parietal vibrations* as in a normal condition. This phenomenon is no longer met with when the lungs are separated from the thoracic parietes by a certain quantity of liquid."

The division of the volume which is devoted to the organ concerned in the circulation of the blood, is amongst the best in the work; it contains much original information, communicated with great perspicuity; but we shall quote no more, lest, without sufficient justification, we lay ourselves open to the charge, after treating the literary product in our critical alembic, of leaving only the *caput mortuum* for the benefit of the author.

The second part of the book is appropriated to the mode of applying auscultatic principles to the diagnosis of particular diseases, and these are arranged into affections of the abdomen and pelvis, of the organs of respiration, and of the organs of circulation. Upon the whole, we can, in strict justice, recommend this "compendium" as a faithful and intelligent guide to all those who are desirous of learning the art of diagnosis by auscultation.

The Cyclopædia of Anatomy and Physiology
 Edited by R. B. Todd, M.B. London:
 Sherwood.

THE publishers have now issued a sufficient portion of this work to enable us to form a better estimate of its claims to support, than when it last received a notice at our hands. Parts 1, 2, 3, and 4, are before us, and we think that they afford materials for forming a correct general view of the plan and scope of the undertaking. On examining the subjects selected for explanation and description, we find the editor apparently chargeable with some faults of

omission; but as the arrangement of topics is alphabetical, the deficiencies may be rectified in the future Parts, and we consider it probable that the *Cyclopædia of Anatomy* will ultimately supply an acknowledged hiatus in the literature of Great Britain.

The articles which have already appeared are for the most part well treated,—the natural result of a good selection of authors, in the list of whom, indeed, are the names of very many gentlemen of whom we may say, without any incautious respect for the authority of mere fame, that their engagement on the work affords a pledge that it will contain a large number of very excellent encyclopedic essays. The announcement of some of the "*minora sidera*" certainly excited a smile, and some surprise, perhaps. Their light, however, though simply twinkling, and not brilliant, may yet prove useful. As the Scotch say, "Many mickels make a muckle."

The nature and variety of the subjects embraced in the plan of the Cyclopædia are well known through the advertisements. The plan combines *Physiology and Anatomy* (Human and Comparative), with the essentials of *Animal Chemistry*.

With regard to the details of such a work, it is not in our power to give any useful account of them here. In speaking of the execution of the articles, we may particularly allude, for their excellence, to those on "Absorption," "Age," "Arachnida," "Aves," "Blood." Let us, however, take the opportunity of suggesting, that, as the work will necessarily be an expensive one, it is incumbent on the Editor to interpose his authority for the prevention of every circumstance that is likely to enhance its price without increasing its value. It should be the peremptory duty of the conductor to revise all the articles, with a view to repress diffuseness of style and redundancy of quotation. The exercise of a capacity to review the facts is not sufficient. The labours of literature, in a redacteur, comprise something more. The connection, also, which exists between the subjects of Zoology and Comparative Anatomy should not be broken, but to decide upon its extent the judgment and official powers of the Editor should be called into requisition, or the evil we have mentioned may become a just source of complaint. The engravings as yet given are good, and afford most material assistance in

the comprehension of many intricate portions of anatomy.

In the department of *Comparative Anatomy* Dr. TOWN possesses the assistance of the two chief labourers in that interesting science—Professor GRANT and Mr. OWEN, and every fresh record of the exertions of these able and learned philosophers adds to the gratification we derive from having been the humble means of blending this branch of study in the department of medical education in England. Comparative Anatomy was known to but few as an important division of medical learning until the brilliant course of Professor GRANT obtained universal diffusion in the profession in the pages of *THE LANCET*. The impression of its value and interest is now continually being testified by the writers, and in the schools devoted to our art. Dr. GRANT's "Lectures" constituted almost the only comprehensive and accessible source of information on this subject in the English language. Now the parent has a numerous progeny. The "lectures" of Dr. GRANT, however, will for years stand unique for arrangement and details. But comparative Anatomy has now many labourers in the field, whose fruit is eagerly sought, and duly devoured.

Compendium of the Ligaments (illustrated by Woodcuts), and the various Cartilages, Synovial Membranes, Bursa Mucosa, and Bones of the Joints; the Dislocations, Fractures, Physiology, and Pathology. By A. M'NAB, M.R.C.S., London: Kershaw, 1835.

THIS work is a synopsis of the principal facts relating to the anatomy, physiology, and pathology of the joints. The author remarks that the study of medicine has been facilitated by condensing the writings of good authors, thus affording to all, the means of learning their contents at a cheap rate. The fibrous structures especially, which are in immediate connection with the joints, are in general described in voluminous works, and these descriptions are dispersed through different chapters. Mr. M'Nab does not profess to present us with any thing novel, but he has collected his facts with industry, and arranged them with judgment.

Respecting the woodcuts, the less that is said of their execution the better. They

serve the author's purpose indifferently, but they are better than none; and in all other respects the volume will prove useful to the dissector, because the details are faithful. To the established practitioner, too, it may serve as a useful "flapper."

THE LANCET.

London, Saturday, January 9, 1836.

No apology can be necessary for resuming, after a very brief interval of time, the question of founding a national University in this metropolis. We must regret appearing to be tedious on this or on any other subject, but we must hope that the objects which it is sought to accomplish by establishing the new institution, are of so important a character, and must, in their results, be attended with so many mighty consequences to the country, that too clear a view of the whole of the circumstances involved in the consideration of the proposed scheme, cannot be taken in the present early stage of the inquiry. If the members of the Government proceed with any degree of precipitancy in this matter, they will erect a monument to perpetuate their own folly. In giving the executive Government credit for the best intentions towards the objects of science and the interests of the country, we cannot refrain from reminding them that something more than mere evidence of purity of motives is required in founding a great national institution, which is to be devoted to the culture of the powers of the human mind.

In contemplating the objects for which the University is to be called into existence, the principle on which it should be founded, and governed, is not less apparent to the intellect of the philanthropist, than to the philosopher, than is the sun at noon-day to the senses of the rudest savage of the forest. How, then, can the best thought or the wis-

position be sanctioned, or even tolerated, of *narrowing* the operation of that principle, to the functions or boundaries of two or three recognised schools, or institutions. The ratification, by ROYAL CHARTER, of so monstrous a proposal, would undoubtedly tend to bring the Ministers of the Crown into contempt, because it would evidently have a *tendency* to make them appear as the abettors of monopolies, or of signalizing them as persons of too contracted an intellect to frame a scheme of University Government which should be national in its principles, and national in all its arrangements and functions. There is one sign which ought to warn them of the dangerous ground on which they now stand. We allude, necessarily, to the approval of the scheme by nearly the whole tribe of medical corruptionists and monopolists. Why have those persons given to it their sanction? Because they are well aware that if the University be founded strictly on the plan of the CHANCELLOR of the EXCHEQUER, that the result will be a failure. These persons have sufficient cunning to know that if an University be not rich in its endowments, it cannot receive general support upon any other ground than on the solidity and extent of its reputation. In the instance before us there are NO ENDOWMENTS, and, unless REPUTATION be first secured, *it is not likely that any endowment will speedily exist in the new University.* Upon these views the calculations of the entire gang of corruptionists and monopolists are founded. In the infancy, at the *very outset*, of the institution, unless the University take a high, an elevated position, in the opinion of the enlightened portion of the public, *the candidates for the degrees will scarcely outnumber the members of the examining council.* And we ask, *secondly*, What can be the extent of its REPUTATION, if the scheme be only calculated to give sanction, and support, to the odious and fraudulent system of "recognising" particular schools, which has been so long practised in the universities, and all but defunct,

old medical corporations? This question should be answered, deliberately answered, by the Ministers of the Crown, before they proceed with their project one step farther. We repeat, that precipitancy on this occasion, will plunge them into an ocean of troubles and difficulties. How often does it happen that in discussing the details of a measure of reform, the principles which called that measure into existence, are either wholly misrepresented, or are passed over in silence by the disputants. Who can have forgotten the reasons which were publicly proclaimed for founding *University College*, viz., that the youth of the metropolis might enjoy the benefit of an University education; and, *secondly*, the establishment of an institution in which University honours might be acquired by all persons, without reference to religious creeds and distinctions? The objects, therefore, and the means of securing them, were resolvable into one general principle, of a wholly national character. Here we observed that the vile and sordid practice of "recognising" particular establishments, to the exclusion of others, in awarding University honours, was scorned and repudiated, not indeed so much in words as by the very principle which conferred upon the new institution life, energy, and strength. The partialities of Oxford and Cambridge had long been denounced, because it was generally felt, by the more enlightened portion of the empire, that in those Universities, bigotry and religious prejudice had often but too much share in making candidates successful in their applications for degrees. The "recognition" in those institutions was not of a favourable description, unless there was a "subscription" to certain articles of belief,—an exaction of too intolerant and odious a character to be any longer endured by the members of a well-informed community. What, then, are we to have in the new University of London? Not, indeed, the demand of a signature to "certain articles of belief,"—not a "subscription

tion" to a particular creed,—but the evidence of a subscription of money. In the one case the DEMON OF BIGOTRY is to be propitiated; in the other, the DEMON OF WEALTH.

We can scarcely say which DEMON is the most hateful. Both demands are equally obnoxious to the cultivation and the free progress of the human intellect. The stigma, the brand, of partiality, is manifest in both cases, and although some excuse might be found in the instances of Oxford and Cambridge, for an adherence to a line of policy, which may have been justified by the circumstances of the period when it was first suggested and set in motion, yet there can be no just ground whatever, while establishing an University in this empire, in the nineteenth century, for rendering wealth, or, more correctly speaking, the non-existence of wealth, an obstacle, as gross and obstructive with reference to the procuration of University honours, as was that of religious intolerance in the fifteenth century. We again ask, "What is it that the Ministers design to reward?" and in answering the question we trust that the real sentiments of the individuals will not be disguised by a liberal display of plausible words. If the portals of the new University be thrown open to candidates, without any regard to the places of their education, and no other introduction to the examination be required than is to be found in the testimonials of an unimpeachable moral character, the University of London would at once far excel, in reputation and utility, every other University in Europe. But if Ministers, in setting this national institution in motion, require that it shall be reached only through two or three "recognised" TOLL GATES, representing only new colleges, or old corporation schools, it will but exist, as we have already said, as an unhappy evidence of the absence of sagacity and foresight in the minds of its founders. There can be no mistake as to the result. The gift of prophecy is not required in this instance to

foretell the state of the future, for in the very arrangements which have already been suggested, there are seen the elements of disunion and decay. If the "recognitions" of the senate of the new University are to be confined to particular schools,—the funds, the buildings, and the general arrangements of which appear to be capable of accomplishing the objects which are specified in the University curriculum, then it must be at once confessed that the new institution is not dedicated to the knowledge, but to the wealth of the nation. It would be another costly and pernicious sacrifice to the power of GOLD. Have the members of the medical profession forgotten the anathemas which have for so many years been fulminated against the President, the Censors, and the Fellows, of the London College of Physicians? And what has been the offence committed by those parties,—the one offence which has obtained for them either the hatred or the contempt of every liberal-minded physician or surgeon in this kingdom? It was simply this,—that they refused to examine any candidates for the Fellowship of their College who had not obtained degrees in medicine at Oxford or Cambridge. Really this is a striking fact. It was owing to the existence of this disgraceful partiality that the recently-established University College received the warm and generous support of so many enlightened medical practitioners. The Fellows of the disgraced College of Physicians have contended, and still contend, that the charter has ever empowered them to make exceptions in favour of graduates of our two ancient Universities. What, then, are we, in founding a new institution, to create other exceptions, which must prove as obnoxious and pernicious as those which are already in existence? The Fellows of the College of Physicians and their conduct have utterly ruined, not only the respectability, but the utility, of their institution. Had they acted courteously and invitingly towards the talent of the country, instead of bearing themselves

insolently and haughtily to every candidate who had failed to expend—uselessly expend—many valuable years of his life, and many hundreds of pounds sterling at Oxford or Cambridge, that College would at this moment have been taking the lead of every other medical institution in Europe, in all matters relating to the interesting and important science of medicine. From acting, however, in the odious system of restriction, partiality, and monopoly, the College of Physicians carries with it not the slightest degree of influence with any ten individuals belonging to the least-informed members of the profession. Every man, therefore, who prefers honesty of purpose and comprehensiveness of principle rather than intrigue, monopoly, and narrow-mindedness, will learn with a sense of loathing, if not with a feeling of horror, that our present liberal Ministry have, even for a moment, entertained the idea of framing a charter, in which, under the authority of the sign-manual of the King, there should be constructed, in the year 1836, some new arrangements for carrying on, with increased vigour, the old exploded system of favouritism, recognition, and monopoly.

"But," it will be remarked, "if distinctions be made in favour of *University College*, *King's College*, and two or three other establishments, will not the privileges thus conferred, prove of great advantage by raising the standard of education in those institutions?"

If this observation be well founded, are the utterers of it to limit the general tendency of its application? If the standard of education is to be raised in two establishments, why not in six, and if in six, why not in all that the country can produce? This would be a real national benefit. Then, indeed, a stimulus would be given to the cultivation of literature and a knowledge of science, which the existing monopolies would be impossible to destroy, or even to weaken. In framing the charter, therefore, we call upon a liberal Ministry to ab-

jure all distinctions, partialities, and exceptions, with reference to Universities, or scholastic establishments, of whatever description. At the same time we desire of them to insist, that the senate of the new University shall require from the candidates for the degrees, such proofs, furnished orally and in writing, of an extent of qualification which shall entitle the candidate to receive the honour which he is anxious to obtain,—the University distinction which they are empowered to award. In such a scheme no sanction will be given to "curricula" for "the schools." The examination alone will, in such cases, necessarily determine, in the best and most effective manner, those subjects of study which ought to be presented by the professors to the attention of the student. The object to be attained, will be the natural and rational stimulus of the pupil, and the subjects to be included in the public examination before the senate, will necessarily determine what shall be the qualifications, and what shall be the duties, of the professors and lecturers in the chief scholastic establishments of the empire.

Under some such scheme as this, the new institution would rise at once into beauty and grandeur, as an offering rendered to THE GENIUS OF THE NATION. If, however, it is to be made a thing of "shreds and patches," of jumbles and exceptions, distinctions and partialities, it will be called into action under the influence of an unworthy spirit, and as such, it will remain an object of perpetual reproach to its well-intentioned but deluded founders.

Since the foregoing article was written, a report has reached us which is in no respect curious, except for the malignity of the falsehood on which it is based.

It is stated that the CHANCELLOR of the EXCHEQUER, after having received deputations from those two filthy dens of monopoly and corruption, the College of Physicians, and the College of Surgeons, has referred the arrangement of the University

question, so far as the medical department is concerned, to Dr. CHAMBERS, Dr. HOLLAND, and Sir BENJAMIN BRODIE. This is the report. This is the falsehood. If Mr. SPRING RICE could have given,—but why should we say if? The thing is impossible. Still, we say, if Mr. RICE have listened in silence to such a proposition, he ought not to escape without being reminded of what was said by himself in the House of Commons, when the Lords examined the *Town Clerks* of the old Municipal Corporations, as to what had been the result of the *old system of Government*, and what might be expected from the new. That the corruptionists, for very obvious reasons, will resort to every species of stratagem, and every manoeuvre, in order to delay the settlement of the University question, is sufficiently plain to the least discerning individual, but that Mr. SPRING RICE or his colleagues will fall into any one of the many snares which are set for him and them, by the wily enemies of a liberal system of medical education and national improvement, is a misfortune which, we believe, cannot occur. It may be well, however, to tell the CHANCELLOR of the EXCHEQUER, that no two corporations in the United Kingdom of Great Britain, are so thoroughly, so heartily, detested by, probably, at least, fifteen thousand medical practitioners, as are the London College of Physicians and the London College of Surgeons. If, therefore, any liberal-minded legislator turn his attention towards these establishments, it must be in the hope of avoiding every thing that is sanctioned or practised therein—to *imitate*, nothing.

WE have observed with much satisfaction, that the new Town Councils have in several instances been addressed by medical gentlemen, who have been soliciting the appointment of Coroner for the borough. If this office is to be anything but a nullity, it must be filled by a gentleman who has been made equal to the discharge of its duties by a medical education. It is worse than

foolish, because it is actually wicked and mischievous, to require any person who is not thus qualified, to execute the important functions which Coroners, at the great majority of inquests, are necessarily called upon to discharge.

THE concours for the chair of clinical surgery, now vacant in the Faculty of Medicine of Paris, commenced on the 2nd of this month. The candidates were, MM. SANSON, GUERDON, BERARD jun., LEPELLETIER, and BLANDIN, who all competed last year in the concours, which we reported so fully at the time. In addition to these gentlemen, we find only three new candidates, MM. JOSEPH DE LAMBALLE, SEDILLOT, and LAUGIER. M. LISFRANC, convinced of the impossibility of being received amongst a body to which he has always been hostile, has retired from the field; although, curiously enough, he has since been sent as one of the four judges, by the *Academy of Medicine*.

THE concours, in Paris, for the anatomical chair, will not open before the 14th of April next.

SOME months ago, MOISE-MONTE-SANCITO was elected a corresponding member of the *Royal Academy of Medicine*, Paris. At the last sitting of the Academy, M. GUENEAU announced that M. MONTE-SANCITO was unable to avail himself of the honour conferred upon him, as the *Austrian Government* refused their authorization to accept French degrees.

INTERCEPTED LETTER.

"DEAR DR. MACHMICHAEL,—You must apologize to my numerous friends who have been making anxious inquiries about me and all my concerns, and you must explain to all of them how impossible it is for me to resume at once my many arduous functions, immediately on my arrival in this labyrinth. You can scarcely imagine the effect of a change of subjects for contemplation, and of objects around me, and how difficult it is particularly for a person as unused to it, to get into habits of business, after having for so long a time indulged in ease and indolence, and in the pleasures of a country

life. BUSHAFANT, whose gigantic intellect enabled him to contemplate mankind in all its relations, made an observation, when on his flight from Russia, which has been often brought to my recollection, and which is particularly applicable to myself at the present moment. NAPOLEON, on his arrival at Wilna, had taken up his residence for the night at the house of the mayor of that city, and whilst walking about the room, in sullen meditation, began talking to himself,—for the Emperor was accustomed to put questions to himself and then reply to them. In the midst of the soliloquy he was heard to exclaim, “Good Heaven! how strange! There is but one step from the sublime to the ridiculous!” Now, far be it from me to compare myself, in many respects, with the great NAPOLEON, but I cannot help perceiving the accuracy of his observation to be applicable to myself, under present circumstances. To tell you the truth, my good friend, my position as a country squire, living richly in my own domains, never being visible beyond my own territory, unless in a splendid carriage, with four prancing horses,—this *sublime* state, contrasted with my avocations here, makes me feel that I am, at this moment, assuredly in a *ridiculous* plight, being every instant liable to be called to Kensington, or some other such place, to feel the pulse of a princess, and to look at her tongue, and then, perhaps, directly after, being obliged to address myself to her French maid, *Mademoiselle Nannette, eyes la bonte, ma chere amie, de montrer le pot de chambre.*” This, however, as you know, is only one of the many disagreeable things that the pure physician must submit to, in order to impress on his patient a sense of the superior knowledge which he possesses of all *internal* diseases.

“While alluding to NAPOLEON, there is a point to which I cannot but refer on this occasion, as one wherein I possess an acknowledged superiority over the late Emperor; I mean in my *classical learning*. His biographers tell us, that he was extremely ignorant of the *dead* languages, and that when he was at Brienne, receiving his preliminary education, such was his backwardness in acquiring a knowledge of Greek and Latin, that he procured with difficulty admission into the *École Polytechnique*. In future life he often alluded to this, and used to quote a passage from LOCKE on Education, wherein that profound philosopher has, incautiously for the interests of our Universities, used these words, “When I consider (says LOCKE) what ado is made about a little Greek and Latin, how many years are spent in it, and what a noise and bustle it makes to no purpose, I can hardly forbear thinking that the parents of children who are in the hands of the schoolmaster’s rod, are the only persons who are the only instrument of their education, and a language

or two to be the whole business of education. How else is it possible that a child should be chained to the oar for seven, eight, or ten of the best years of his life, to acquire a knowledge of a language or two, which I think might be had at a great deal cheaper rate of pains and time, and be learned almost while playing?”

“You must not suppose, my dear friend, that the time which I have spent in the country has been altogether lost, or that it has been uselessly employed. It is under circumstances of rural retirement, that I have experienced the extended benefits of that strict moral and virtuous course of education which I received at Oxford, and that I have been able also to reflect on the immoral and licentious habits so generally practised in my time by the students of the University of Edinburgh. ‘The idea of rural felicity,’ observes an enlightened writer, is so congenial with the human mind, that we cannot wonder to find it cherished amidst all the hurry and dissipation of public life, especially if we consider that such a life is often attended with labour and sorrow, with weariness and disappointment. When we look abroad into the world, we see one man fixed down to his desk, or stationed behind his counter, and from morning to night busily engaged in arranging his accounts, or dealing out his commodities, with scarcely sufficient intervals for the refreshment or support of nature. We see another, aspiring after some place of honour or of profit, wrapt with suspense in the pursuit, frequently baffled in his object, and if at length successful, dissatisfied with the acquisition. While a third, whose situation may appear more enviable, who,—alike exempt from the toils of the city and the ambition of the court, has no other concern than to enjoy the amusements and pleasures of life,—is often found a miserable prey to chagrin, from the caprices and jealousies which are sure to infect the brightest circles of gayety and fashion. In all these cases the mind naturally looks forward to the country, to the independence of some rural retreat, the peaceful labours of husbandry, the diversions of the field, or the scenery of nature, for purer sources of enjoyment. How true is the language of THOMSON:—

‘Retirement, rural quiet, friendship, books,
Ease and alternate labour, useful life,
Progressive virtue, and approving Heaven!’

“Besides participating in the amusements and recreations of a country squire, I have occasionally employed myself in reading those classic authors from whom I derived such delight when at college,—a source of intellectual pleasure which no one can appreciate, except he who has partaken of it. I have not troubled my head much, as you may well believe, with reading *professional books*. Indeed, excepting Mr. WANDROP’s work on blood-letting, I have not obtained much

pleasure from any other literary production, and that book I have not only perused with great attention, but have interspersed it with notes on the blank-leaf copy which you were so kind as to procure for me, and which copy, now that it contains my notes, I think would be a very useful present to our College library. His knowledge of medicine not being limited to surgery alone, he has been enabled to treat the subject in a much more comprehensive manner than he could have done had he not possessed a thorough knowledge of physic. It is there where general practitioners have advantages over the *purse* grades. Indeed, I am free to confess, and it matters not for me, at my time of life, to let it be generally known, that I have often had occasion deeply to lament my ignorance of surgery, and I shall take some favourable opportunity of pointing out to the younger fellows how seriously their worldly interests are affected by their ignorance of that art, and the bad habit most of them have of affecting to sneer at everything like a knowledge of those diseases which require surgical aid.

"Now that I am once more amongst my professional brethren, it behoves me to devote all the energies of my mind to promote the good of our great cause, and as I can expect but few patients at this season of the year, I shall not fail to ponder well on College matters. The granting of licenses must not be delayed a day, and you may order Dr. ASHWELL to come first before us, on trial. The very idea of these German doctors makes me smile. But we must treat the matter gravely. So long accustomed as we had been to license the Scotch dubs, I never thought anything about *them*, and certainly we had some first-rate men amongst them, but to have to do with a squad of Dutchmen is really quite ridiculous; and if it were anyhow possible to keep the machine in Pall-Mall going without granting their admission, we should not run the risk of placing within our enemy's reach so powerful an engine of satire. I always remember, with regret, the laugh against us for inducing the good ARCHBISHOP to give CHARLES CLARKE a degree. But as things are, we must fearlessly adopt extreme measures.

"Next to the 'ways and means,' as my dear friend Sir ROBERT PEEL calls them, comes the Metropolitan University. Here we must strain every nerve. As I told you before, I have never been consulted by any member of the Government, directly or indirectly, at which, however, I am not surprised, considering that I think and act so differently from them on all points, and especially as they must know how cleverly I prevented the Peel-Wellington Administration from making any changes in Pall-Mall East. I do not myself see how we shall avoid being swamped, and I do augur

that we shall share the same fate as Lincoln's-Inn-Fields and Blackfriars. All that I can gather about the matter, on which I can depend, is, that the whole system is already arranged. BACON has been, I must do him the justice to say, most diligent; and as he can, with equal ability, simulate a Tory, a Whig, or a Radical, he is just the man for that kind of employment. I only fear that should he see his way clear, he will throw his friends at Lincoln's-Inn overboard, and accept office. He must be watched closely. Neither would I trust Sir ASTLEY, notwithstanding all he says, if the *certificate*-system he wholly exploded. He flourished and lived under it, and its annihilation would be disastrous to him, had he not something else to look to. I rejoice to learn from Lady BRODIE, that Sir ASTLEY has taken a *serious turn* latterly. It is such a *revolution*, that I can only *hope* it is true. I do not expect that we shall get much good from the negotiations of HOLLAND and CHAMBERS. HOLLAND having endeavoured, after being a Whig all his life, to cut a favour with the Tories, when every rational man must have believed that they would hold office for ever, and having, now that the Whigs are in power once more, again become a Whig, I have no faith in him. His opinions will not be hearkened to; even the sweetness and simplicity of his manners will have no effect. CHAMBERS is too lofty and rough, and wants that *suaviter in modo* which gives me so much influence over the human mind. Let TUPPER, NUSSEY, TEGGART, PELLER, and all the top men in that line, know of my arrival. I have yet seen no one but Madame V., whose case, I am happy to say, I have hit exactly. I discovered that she has an affection of the *heart*, and I told her that the system of treatment which I would adopt was mild, and unattended with pain or danger, and that a ——— might also be required to perform a *radical* cure. Write a paragraph for the *Sunday Times*, announcing my having been consulted on this interesting case, and believe me always yours,

"H. H.

"Curzon-street, Dec. 1835."

ADMINISTRATION OF CREOSOTE,

AND SOME OTHER MEDICINES, NOT ALWAYS REMEDIALY SUCCESSFUL.

To the Editor of THE LANCET.

SIR,—I have perused the account of a case of spasmodic affection of the stomach, with vomiting, not relieved by creosote, in THE LANCET of Dec. 24, signed by Dr. Walker, in the latter volume he refers to a

lately-published clinical lecture delivered by Dr. Elliotson. The cases recorded by Dr. Elliotson are three, as Dr. Walker admits, and the case now related by Dr. W. is but one case; I think, therefore, that he ought to have carried his observations farther. By reference to other clinical lectures of Dr. Elliotson, Dr. Walker would have discovered that Dr. E. has had cases in which creosote has failed to relieve gastrodynia and vomiting, as well as Dr. Walker, and that Dr. Elliotson, therefore, does not anticipate invariable success in the use of that medicine. There are many circumstances which materially modify the action of medicines, which must be taken into account. Thus, there was a case in our hospital last week, in which prussic acid was given to allay gastrodynia and vomiting; but each dose of the medicine increased the vomiting; but, on looking to the mode of exhibition, there was discovered the cause. The patient was taking the hydrocyanic acid in peppermint water, and that made him vomit. Peppermint is known to have this effect with many people. On substituting cinnamon water for aq. menth. pip., the medicine immediately had the desired effect, and she was discharged cured in a few days. Now Dr. Walker administered the creosote in his case in mucilage, and how do we know but that it was the mucilage, and not the creosote, that caused the vomiting? Nay, there is now a patient in our hospital who could not retain on his stomach a dose of a mucilaginous mixture which she was taking for a cough, although she did not vomit on taking other things. Again, ascribe the effects produced to the creosote, and even idiosyncrasy might play its part. There are those on whom medicines of various sorts have very unusual effects. Thus, a patient in our hospital last month, had her gums become tender whenever she left off mercury, and they got well again as soon as she resumed it.

We can only account for such anomalous cases by regarding them as the result of idiosyncrasy, so that by that same cause it will and does happen, that with one patient creosote will answer best, with another opium, with a third prussic acid, and so on. Accordingly Dr. Elliotson does not employ creosote indiscriminately, as might be inferred from Dr. W.'s letter, or from the perusal probably of one clinical lecture, but at this moment he is giving to one patient prussic acid, to another creosote, and to another stramonium, to allay pain in the stomach and vomiting. In the case in which he is giving stramonium, creosote succeeded for a while, and afterwards proved unavailing, and now stramonium affords relief. In another case prussic acid failed altogether to relieve vomiting, which ceased after the first dose of creosote (see *in sq.* 31). In others, prussic acid avails where creosote fails; but, certainly, in point of efficacy, none of them surpasses

creosote; and in very many cases it has proved beneficial after the failure of everything else; but then it must be administered in different ways, according to circumstances; and as to Dr. Elliotson's "plan" being "two drops in mucilage and water every six hours," that is not at all the case, for he usually gives it in plain water, and sometimes is obliged to increase the dose to twenty drops or more, and that not only every six, but every four, or every three hours.

I would not have written in answer to Dr. Walker's letter had he not committed an error which is likely to do much mischief, and is too often repeated,—viz., that of drawing general conclusions from isolated facts. In another medical periodical, a week ago, Dr. Elliotson is censured for his indiscriminate use of iodine, as though he employed it as a panacea—as an universal remedy for all diseases, which no one who knows anything of that gentleman's practice can for a moment assert. It may not be amiss to state here, what is not generally known; viz., that if creosote be not very carefully purified, it contains an emetic substance, which passes over with it in the distillation. This fact was unknown to the chemist who first prepared creosote; and, consequently, much of the creosote which he at first sent into the market, actually contained a most powerfully emetic substance. Hence, perhaps, in part, have arisen the discrepancies with regard to its virtues as an anti-emetic. I am, Sir, yours respectfully,

A STUDENT AT THE NORTH-
LONDON HOSPITAL.

Dec. 22, 1835.

. We object to opening our columns to the controversy which would arise from the publication of some passages and remarks which we have omitted—but without at all interfering with his legitimate object—from the letter of our correspondent. We have endeavoured to limit his statements to facts which may here usefully obtain insertion.

MEDICAL MAGNETISM.

To the Editor of THE LANCET.

SIR,—The candid impartiality with which you listen to both sides of any question that may be brought before you, assures me that you will give a place in your journal to the following simple statement of facts—

Mr. DAVIDSON says, in his letter inserted in last week's LANCET, that he regrets having been mentioned in connection with the subject of mineral magnetism. Now this can be a cause of regret with Mr. D. I am at a loss to conceive; he was not forced into

the subject, but came forward of his own free will, to make some statements to defend some friends.

To crush out at once, Mr. D. brings forward formidable names. He says, Drs. Faraday and Ritchie deny any curative property in the magnet! However valuable the authority of these names in every other respect may be, it is inadmissible in this, as based upon theory only. One fact certainly is worth all the theories in the world. Neither of these gentlemen will hold a thing impossible because he does not see how it is effected. This would be unphilosophical indeed! Mr. D. further states, that there is nothing new in my method. Now Mr. D. ought to have stated at the same time, that he is incompetent to give an opinion, because he himself allows that he knows nothing of the magnet. The gentlemen on whose authority Mr. D. seems to make this statement, are neither of them fully acquainted with my views, and they certainly would not wish to condemn any one's opinions before hearing them. And though it is with the utmost reluctance that I make use of names, I believe that I owe it to myself to state, that Mr. Faraday pronounced my views, as far as he was aware of them, to be new on some points, and worthy of investigation. Singular it seems to hear opinions quoted, which differ essentially from those expressed by the parties themselves. Dr. Ritchie said, before the Westminster Medical Society, that in magnetizing, both poles were produced simultaneously. Now this is certainly different from what is said by Mr. D. As to myself, I do assert, that in magnetizing, the poles produce their like and not their opposites; all magnetizing is but a continuation of the like pole, and quite the same whether by contact or induction. I finally maintain, that like, and not opposite, poles assist each other. By simply following out these views, I have succeeded to obtain results, both in the construction and application of the magnet, not achieved before. My magnets are more powerful than others, because they are constructed on what I conceive the right principles.

It will be fresh in the recollection of every member of the Westminster Medical Society then present, that it was with considerable reluctance I accepted Mr. Hale Thomson's kind offer to experiment on amaurotic patients in the Westminster Ophthalmic Hospital. I say with reluctance, because I foresaw the objections that could be raised against experiments on the eye. It is moreover well known that many cases of amaurosis are accompanied by organic changes, and that but few are purely nervous. Mr. D. says I selected four cases as favourable for the magnet. This is a mistake; for though I considered one of the cases rather favourable, I did not consider the three others to be so; because one of them is ac-

companied by glaucoma; the other became amaurotic after an epileptic fit; and the third had been operated upon previously for cataract, when a piece of the capsule remained in the posterior chamber.

Mr. Guthrie, moreover, has kindly expressed himself several times, that none of the cases could be considered appropriate. Now in the one case I excepted, the patient professes to have received considerable benefit; the same, though in a less degree, was the case with two of the others. In most cases where the magnet is used, it is applied over the clothing and does not come in contact with the body, when, of course, no objections as to effects produced by the metal only can exist. And now a few words with regard to what Mr. D. calls an inquiry after truth. In the first place, I think it would have been fair to have stated that I at once admitted that cold would produce lachrymation, and that I applied the cold iron, fully expecting it would do so. But I say that iron will not produce that great mobility of the iris, which follows the application of the magnet. There can be little doubt but a piece of cold iron will produce similar effects on the eyes of four or five healthy individuals, but not precisely the same, as Mr. D. says, for on some it would not produce any perceivable effect whatever; others would feel heat, and some both cold and heat. But what has this to do with the magnet? Mr. Thomson not remembering that cold iron produces lachrymation, very naturally considered it as one of the effects of the magnet, and he certainly would have taken an opportunity to correct his mistake, had such occurred. To me Mr. D.'s inquiry after truth, seems a wish to tell the public what great authorities are opposed to the magnet being used as a remedy, and to make them aware that he is of the same opinion. I remain, Sir, your very obedient servant,

CHARLES SCHMIDT.

137, Regent-street, Jan. 5, 1836.

TWO CASES OF GLANDERS IN THE HUMAN BEING, CURED BY CROKOTE.

Related by Mr. J. P. CHEETHAM, London, in,
the Veterinarian, Jan. 1835.

THE susceptibility of the human frame to contract those dire maladies designated by the terms glanders and farcy, has now been almost as clearly demonstrated as the want of power to resist the virus of smallpox. It is with much pleasure that I am enabled to direct the attention of the readers of your useful Journal to two cases of glanders in men, that have been successfully treated.

A summary detail pertaining to the appearance and history of the affected horse will exhibit the nature of the disease.

In the month of April last, I was requested to examine a bay horse declared to have a common cold, with secretion of pus from the nostrils, but which had continued during an inordinate time. A person who shall be nameless, forwarded some balls that were said to be infallible. The owner, in order to be assured that they were administered, gave them himself; but not being very expert in this occupation, he lost a part of the cuticle from the knuckle of the fore-finger.

The symptoms presented by the horse were, the glanderous discharge with the fetid effluvia; extensive ulceration of the pituitary membrane covering the nasal septum; enlarged and indurated lymphatic glands, occupying nearly the whole space between the posterior maxillary bones, projecting beyond their margins, and displaying themselves even to the sight; and the cough short and difficult, indicating the tubercular condition of the respiratory organs. His coat and outward appearance, however, presented an apparently healthy aspect.

My advice was to destroy him, being certain of his death, and likewise knowing the danger of propagating the disease to other horses, and to the persons who were in attendance. The owner was unwilling to sacrifice his favourite, and pressed me to give medicine, valuing neither time nor labour. In order to satisfy his mind, I ordered the blue draught (sulph. cupri) to be administered twice a day.

In the course of a week after this, the owner informed me that the horse had amended. Considering this rather a strange anomaly, I forthwith visited the patient, and satisfied myself that, instead of amending, he was quite the reverse, for blood was interwoven with the discharge; the breathing was laborious and difficult, and, especially, it was accompanied by a very peculiar sound in the nasal passages. In a few weeks the proprietor told me that the horse had been sent to the knackers' yard, and at the same time I heard that he and his man were similarly diseased.

The smell and the discharge were of an identical character with those emitted by the horse; and on examination my opinion fully coincided with his. From the resemblance of the characteristic symptoms in both, a general description will suffice. The virus was conjectured to have entered the system, through an abrasion of the skin, on the back of the hand, and in the other, through the medium of a sore on the lower lip.

The lapse of time prior to the appearance of the disease is not known. For a long time they continually smelled the mucous efflu-

vium that proceeds from glanderous matter; there was an increased secretion of mucus from the nose, which was attributed to mild catarrh, until the character of the discharge, the blood intermingled with it, pain in the frontal sinuses and the cavities of the nose, and short and interrupted sleep, roused them to a state of anxiety.

The pus with its gluey, slimy, glanderous appearance, satisfied me as to their real state. I could discern no distinct ulcers on the pituitary membrane; but from the statements given by the patients, I should incline to decide that they existed in the remote parts of the nose. The throat, on pressure, was rather painful, and the lymphatic glands were enlarged.

These patients having come so much under my own observation, I shall give some account of the treatment of their respective cases by Dr. Elliotson. The servant was admitted into the North-London Hospital, and the master attended by Dr. Elliotson.

By injecting a solution of creosote in water up the nostrils thrice a day—by this simple means, and this alone—the servant was brought to a state of convalescence in ten days, and the master in a little longer time. If the local application of the creosote had proved insufficient, it would have been administered internally. The strength of the injection was changed according to the stimulating effect produced. At first the cases admitted of two minims to the ounce of water, until the parts began to alter their morbid state.

These facts will add to the triumph of those speculative theorists who consider that glanders is a mere local affection. My purpose here is not to open the way for controversy on a disease that every pretender assures himself he possesses a specific for. The cases, however, are worthy of record. Perhaps they may lead to a course of experiments on the power of the creosote over this pest of the equine race. Let these experiments be fairly conducted, and let us cease to annoy others with our fanciful opinions, and wait until the treatment of glanders can be founded on a rational and secure basis.

[In a paper in the last volume of "The Transactions of the Royal Medical and Chirurgical Society," Dr. Elliotson refers to the above two cases. "I am anxious," says he, "to mention its effect (the effect of creosote) in two cases of chronic glanders, affecting one nostril and the frontal sinuses with pain, and a copious and fetid discharge. The disease in the two persons was clearly contracted from a glandered horse; and I purpose doing myself the honour of laying the facts before the Society early next Session, as I never read of or met with an instance like these in the human subject, former cases having been acute glanders or chronic farcy. The sedulous injection of a

weak solution of creosote up the nostril removed the whole of the symptoms after a very few weeks, and I hear the patients are still well. I need not say that the disease has always hitherto proved fatal in the horse."

With some exceptions, few and far between, and some of them of a very doubtful character, glanders "has always, hitherto, proved fatal to the horse." Should we at length find a cure for it in creosote, although only in its chronic form, the veterinary profession will be under deep obligation to Dr. Elliotson. We shall wait with some impatience for this valuable document, and in the meantime, some zealous veterinarian will, we trust, put the power of creosote to the test in the cases of chronic glanders, and favour his brethren with the result.—*Ed. V.*

GUY'S HOSPITAL REPORTS.

THE example set by Mr. F. SOUTH, an "interne" of *St. Thomas's Hospital*, Southwark, has found speedy imitators in two "externes" of *Guy's Hospital*, its neighbour; and we have before us, consequently, a thick pamphlet under the above name. The circumstances under which this production has originated, the anticipations of its projectors, and the prospects of the contemplated series, must form subjects for our pen on another occasion. At present we shall simply say, that so low is the ebb of literature at "Guy's," that the medical officers have actually been to Bath for an introduction to their work!

Dr. Bright "opens the ball." We have danced through one fandango with the old lady, and below present our readers with a condensed account of her conversation while performing the labour. "If a man," said the dowager, "have, through ignorance, in early youth, or at any other time, whispered soft falsities in the ear of the public whom he hath courted, he should certainly repeal and amend his tale when he gets older and wiser. I once committed errors of this kind, and deluded those whose favour I sought. In a few years more I saw that I was wrong. I ought to have 'confessed' at once; yet something held me back; but now, after the revolution of many more years, I am going to tell you my faults." Thus tripping on, with tongue and feet, we obtained from our partner the astounding confession that Dr. Bright had, for many

years, abandoned a practice which he had previously recommended for its excellence to the profession, without ever hinting to them until this very day, that that practice was materially calculated to keep up the disease which he originally designed it to lessen. We condense the details,—which are distributed through half-a-dozen pages of the "Reports"—into the following passages. The original article, with a case of "Simple fever, protracted by Irritation of the Bowels, and attended by Relapse," appears in the form of "Observations" or the

TREATMENT OF FEVER.

THE physician should review from time to time his published opinions, that he may see how far experience bears out his former impressions. With this feeling I detail a case of simple fever protracted by irritation of the bowels. Eight years ago I stated my thoughts on the treatment of fever. Additional experience has induced me to make some important modifications, adopted from the practice of others.

In a great majority of the cases of fever treated, more particularly of those which are admitted into an hospital, the period has passed when the febrile action could be cut short. It is established, and, as it must run its course, it is our task to conduct it through as safely as possible. No danger, then, so frequently presents, as that which results from irritation in the lining membrane of the alimentary canal, more particularly in portions of the ilium, the cæcum, and in the colon, generally with great derangement in the digestive functions. To obviate this state, I formerly said that the combination of the hydrargyrum c. cretâ the ipecacuanha, and the compound chalk powder, in different proportions, with the mildest nourishment, caused the symptoms regularly to retire. This practice has been followed by others with great satisfaction, but I now conceive that even this mild combination has, in many cases, kept up the irritation longer than would have been the case, had a more soothing practice been adopted: in point of fact I have not, for many years, had recourse to this combination, except for temporary purposes, scarcely ever now continuing its use in the way I once recommended.

As regards purgatives in the protracted stages of fever, I almost entirely confined myself to small doses of *Hydragryrum c. cretâ*, varying from two grains to five, and followed, in about four hours, or the next morning, by a dose of castor oil, often limited to two drachms, seldom increased to

half an ounce, and never exceeding six drachms, to which I very often add from two to six drops of tincture of opium.

I further observed, eight years ago, "that as a part of the diaphoretic plan in fever, the ipecacuanha wine assisted a free discharge by the skin: but, that in many cases, harm rather than good is done by the use of saline remedies and diaphoretics in any form, as they irritate the bowels. Forcibly impressed with the injurious effects of most of our diaphoretic remedies, I have of late, in a very great degree, relinquished them; and have substituted a remedy, which I was first induced to try, from seeing its very favourable action in the hands of Dr. Addison; that is, the carbonate of soda, in doses of from ten to twelve or fifteen grains, three times a-day, in some mild aromatic infusion, as the infusion of mint; and this now generally supplies the place of all other saline combinations. It certainly irritates the bowels less than most other remedies given in fever, though it is occasionally necessary to guard even this with a drop or two of the tincture of opium. How the soda acts I am unable to say: but sometimes, in spite of all our care, diarrhoea threatens, and the stools assume the peculiar unhealthy appearance which belongs to this character of fever. To check them too suddenly would be wrong. In these cases, I find most excellent assistance in a clyster of a few ounces of Gruel or starch, with a small quantity of the sirup of poppies, varying, according to circumstances, from a drachm to three drachms; and this repeated once or twice, or oftener, in the day, according to the urgency of the symptoms. For this remedy I am indebted to Dr. Robert Williams. I have, in most instances, found it decidedly preferable to the ordinary opiate clysters which I was accustomed sometimes to employ, and which will still be occasionally found indispensable. The advantage of the sirup of poppies over the tincture of opium seems to be, the greater mildness of its action. In that class and stage of fevers to which the present observations refer, I should say—Keep the patient tranquil, shave the head, and apply a cooling embrocation. Let the only food be fresh barley-water, or toast-water; or if, occasionally, a little more support is required, arrow-root and mild animal broth. Give the soda regularly: regulate the evacuations with the hydrargyrum c. cretâ and the castor oil: if the bowels need restraint, use infusions of poppy sirup and starch: if tenderness come on, apply the linseed puddle; or leeches, if the tenderness be urgent. Ascertain the condition of the bladder frequently, by placing the hand over the lower part of the abdomen. If the strength fail, the infusion of aspergularia, with a few grains of the subcarbonate of ammonia, is generally the best stimulant

tonic: when wine is administered, it should be only by the ounce.

The case to which these observations refer was an instance of febrile irritation, kept up to a great length of time, and, when convalescence had apparently been established, a little neglect of diet, with animal food, led to a relapse, which threatened a fatal result. In the onset of the disease, a few grains of calomel, well guarded in their operation, will occasionally be found most decidedly useful, but I am quite convinced that great mischief results, in all stages of the disease, from the incautious use of this remedy.

NORTH-LONDON HOSPITAL.

REMOVAL OF CALCULI FROM THE URETHRA.—Mr. Liston, on the 1st instant, removed three small calculi from the urethra of a little boy, aged four years and a half. The patient had suffered for some time with symptoms of stone in the bladder, and he had been sounded at one of the London hospitals, but no calculus was detected. On his admission here, the sound being introduced, it was found that the urethra was partially obstructed by calculi, about half an inch from the orifice. The grating of the instrument over these bodies rendered the diagnosis, as to the presence of any stones in the bladder, very obscure. Mr. L. removed three small stones of a sub-triangular shape, and of about the size of half a common nut, in the following manner. He introduced a sharp-pointed curved bistoury through the meatus, and widened the passage on each side. The stones were then easily scooped out. Mr. Liston preferred this mode of procedure in this case, to making an incision from beneath the urethra. Had the stones been situated further down the passage, he would, he said, have pushed them behind the scrotum, and cut down upon them through the perineum.

THE TAXIS IN HERNIA.—In a clinical lecture the other day, Mr. Liston remarked that he believed that operations for strangulated hernia were resorted to far more frequently than was really necessary. He believed that almost all cases might be relieved by the steady and persevering application of the taxis, particularly if resorted to within twelve hours in inguinal hernia, and six or eight hours in crural, after the strangulation has occurred. The warm-bath and bleeding might be advantageously employed in many cases. Of course in the use of the taxis, it required in the operator a perfect knowledge of the direction which the hernia takes. It was a mistake to suppose that this application required less address and skill than the cutting operation;

for, in fact, its successful use generally reflected as much credit on the surgeon, and was attended with much less danger to the patient; there was less fear of acute peritoneal inflammation coming on, and, of course, more chance of recovery. It must be understood, however, when recommending the steady and persevering employment of the taxis, that he did not sanction any sort of violence, nor the carrying the application beyond reasonable limits. The first indication in this operation was the reduction of the bulk of the tumour, which was effected by squeezing the air contained in the extruded bowels into that within the abdomen. The pressure was to be kept steadily up for fifteen or twenty minutes, and the contents, if possible, gradually pushed back into the abdomen.

LOCK HOSPITAL.

CASE OF GONORRHOEAL DISCHARGE, ACCOMPANIED WITH CONDYLOMA AND CONDYLOMATOUS ULCERATION.

LUCY CARTER, *ætat.* 17, was admitted on the 13th of March, 1835, under Mr. WALKER'S care. Her complaints, which she has had for more than two months, commenced with severe ardor urine two or three days after connection, and a discharge occurred during the ensuing week. She has had a bubo in the left groin for two months, which gives her but little pain; there is an ulceration in the inferior commissure of the vagina, which she has had for three weeks, and three or four small condylomata at the edge of either labium, which have been there for the same period. She has taken no medicine. Her present symptoms are, a profuse thick yellow discharge from the vagina, scalding in micturition, &c. Her general health is not very good; there is much shortness of breath; general uneasiness about the chest; with pleuritic pain over the right side. The bowels are very much confined. The catamenia have been absent for one month.

She was put upon a purgative plan of treatment, and a saturnine lotion was applied to the bubo and condylomata.

19. The scalding has nearly gone; the sore in the inferior labial commissure presents a turned edge; a small bubo is presenting itself in the right groin.

26. The bowels are very constive, and she has been obliged to take large doses of aperient medicines (*Compound Decoction of Aloes and Rhubarb*) to keep them open. She has also suffered much from weight and pain across the forehead.

April 3. The bowels have been better regulated lately; the gonorrhoeal discharge still continues thick, yellow, and profuse, in

quantity, and there is slight scalding in micturition. There is much excoriation from the ulceration around the orifice of the vagina.

12. The purgative plan of treatment has been continued with much relief to all the symptoms present, both internal and external. The old pain over the forehead and eyes sometimes returns, resembling in the severity of its attacks the low ague.

17. She has had no return of pain in the head since the last report; the discharge is nearly gone; the scalding has subsided, and the ulceration and excoriation are healed. She was discharged this day.

IN the *MOCK LANCET* of last week, RODERICK MACLEOD, the amiable editor, compiler, or fabricator, of that weekly bundle of stupidity the "*Medical Gazette*," "confirms" all that we have said respecting the application which was made to Mr. LISTON, respecting the Chair of Surgery in the University of Edinburgh, and concludes his notice by observing, "With respect to "the gentleman by whom the invitation "was sent to Mr. LISTON, it now appears "that a Mr. DICK was the individual;" and then, echoing *THE LANCET*, RODERICK says,—"This is the whole of the matter." Here, however, the amiable mind of RODERICK will be gratified on discovering that he has committed another mistake, as it is *not* the whole of the matter. The gentleman whom he designates "a Mr. DICK," and who wrote to Mr. LISTON, is the *CONVENER* of the *Town Council* of Edinburgh. Further, we may state that it is known in Edinburgh, that the Lord Provost applied personally to Mr. LISTON, when that gentleman was lately in Edinburgh, to ascertain if Mr. LISTON would take the Chair of Surgery, and the magistrate who takes charge of the College affairs, and who is *CHAIRMAN* of the College Committee, addressed a letter to Mr. LISTON, in which was contained a similar inquiry. Nothing, therefore, more than the following facts, viz. that LISTON having been consulted, and having declined the appointment, Sir CHARLES BELL was then "sounded," and the distinguished knight, having given a favourable answer, received the Chair from the Council,

To the Editor.—Sir,—On Wednesday Dec. 23, at the Board of an Hospital which is known to the medical profession for the great integrity that distinguishes its proceedings of all its members, the following contest for professional respectability took place. A young lawyer, after discussing some knotty points at the Board, indulged in sundry caustic reflections which proved to be very unpalatable to a physician of some notoriety, who replied in his customary manner, and, on resuming his seat, declared that every word spoken by the lawyer was altogether false. The lawyer did not approve of this mode of *arguing* the case, and on rising, declared the fluent doctor, with three emphatic iterations, to be neither more nor less—I blush to say it—than “a liar.” Little more beyond a few apologies to the Board was said, and the doctor retired—to look it was whispered—for “a friend;” but the surprise was wrong, for next day the following pithy dialogue was heard. “Well, Doctor, I suppose you have been to Chalk Farm this morning.” “What!” replied Dr. S., with most feculent look, “to fight with a t—d? No, damme.” High moral contempt no farther could go,—nor better could character be illustrated. I am, Sir, your obedient servant.

Dec. 29, 1835.

MESSES. WATKINS AND HILL.—In a note sent to us by these gentlemen (the whole of which we need not insert), the following statement occurs. The note from Mr. Wilkinson, referred to below, justifies the statement of Messrs. W. and H.:—“If Dr. Schmidt or Dr. Epps had been contented with simply stating that a bet of fifty, or a hundred pounds, was offered by a gentleman (relative to the construction of a magnet), we should have had no reason to complain, but when they gratuitously add that we *accepted* the bet and *failed*, it is really too bad. The truth is, that the moment the bet was offered by Mr. Wilkinson we instantly declined it, and never thought more of Dr. Schmidt or of his magnets, until we saw our names in THE LANCET. The enclosed note from Mr. Wilkinson (to one of our firm) will prove the correctness of our statement. We have been very unkindly and unfairly dealt with in this business by the two learned Doctors.—5, Charing Cross, Dec. 30, 1835.”

O. FRANCIS, Surgeon, of Ipswich, presented himself as a candidate for the office of Coroner in that borough in a circular of which the following is a copy:—
“Sir,—I beg respectfully to announce myself as a candidate for the office of Coroner for the borough, and to solicit your vote on my behalf. I am aware that the duties

of Coroner have hitherto been generally performed by members of the legal profession; but, evidently, for some years past, it has been a growing opinion that medical science may be more advantageously employed in the investigations which come within the province of this officer. Should I be honoured with the appointment, no effort on my part shall be wanted to discharge the trust reposed in me.—I am, &c.”

Mr. Wm. Cooke has in the Press a brief Memoir of the late Sir William Blizard, read before the Hunterian Society, with additions.

A Popular Manual of the Art of preserving Health, embracing the Subjects of Diet, Air, Exercise, Education, Bathing, &c. By Mr. J. R. Davis, Surgeon. London. Whitaker, 1836. pp. 504.

A Treatise on the Diseases of the Eye and its Appendages. By Richard Middlemore, M.R.C.S., &c. In 2 vols. London. Longman, 1835. 8vo. pp. 690 and 858.

On Perforation and Division of Permanent Stricture of the Urethra by the Lancetted Stiletter. With Observations on Spasmodic and Inflammatory Stricture, and other Urethral Affections. By R. A. Stafford, M.R.C.S., &c. 3rd Edit. London. Longman, 1836. 8vo. pp. 322. With Engravings.

Davis's Obstetric Medicine, to Part 43. London, Taylor. *.* This excellent work is now near its conclusion. The plates present some of the best specimens of lithographic drawing which we have ever seen appended to a medical work.

Remarks on the Unity of the Body, as illustrated by some of the more striking Phenomena of Sympathy, both Mental and Corporeal, with a view of enlarging the Grounds, and improving the Application of the Constitutional Treatment of Local Diseases. By George Macilwain, M.R.C.S. &c. London. Highley. 1836. 8vo. pp. 294.

A Practical Treatise on Midwifery, containing the Result of 16,654 Births, occurring in the Dublin Lying-in Hospital, during Seven Years. By Robert Collins, M.D. late Master of the Institution. London Longman. 1835. 8vo. pp. 526.

Practical Observations on Homœopathy with a variety of Cases tending to prove its decided superiority over the ordinary System of Medicine. By W. Brookes, M.R.C.S. London. E. Wilson. 1836. 8vo. pp. 133.

. We deem it right to say, in copying, according to our custom, the title of the foregoing book, that notwithstanding the unqualified statement which is presented in the latter half of the title, the volume does not contain one particle of evidence in support of the declaration which it contains. The name of not one of the medicines

which are alleged to have been administered in the "cases," is given; nor is the name or the place of address of any one of the alleged "patients" appended to any one of the "cases." Indeed, the volume does not afford the slightest ground for believing that the "cases" are any other than fabrications, from the first to the last. Considering the circumstances, in fact, under which the book is put forth, we cannot regard it as any thing else than a mere puff, which is calculated to throw no kind of credit on the professional character of the advertiser.

ificates," "Brandreth's Pills," and "Rowland's Kalydor." A notice respecting the assumption of the F.R.S. may stop at least this new fraud. I am, Sir, your obedient servant, M.R.C.S.—Gower-street, Jan. 2.

We have received a great many letters respecting the attendance of students at the Kinnerton-street School. No one appears to deny that the class amounts to the number stated by Mr. Evett, who we understand fills some office in that establishment, but all of our correspondents challenge the allegation that the entries are those of students who have actually paid for tickets of admission to the lectures and the dissecting-room. It is also as generally declared by our correspondents, that a use has been made of the name of Sir BENJAMIN BRODIE, in persuading pupils to attend the school, which it does not become an examiner in the College of Surgeons to allow, much less to encourage. However, if true, little wonder can be felt at the fact, when it is notorious that Sir B. BRODIE is the largest shareholder in, if not the sole proprietor of, the building. With regard to "free admissions" to the school, God forbid that we should complain that students are allowed to dissect at any school for nothing. Sir BENJAMIN, after the thousands of pounds which he has already drawn from the pockets of students under the certificate system, can afford to let a dozen or two of pupils teach themselves anatomy at his school-room, without charge for a "ticket." Moreover, he may expect subsequently to share in so many sums of two-and-twenty guineas each, for the piece of worthless parchment which is handed to "passed" candidates for the diploma of the College in Lincoln's-Inn-Fields. So that, though the students do not pay PETER at one toll-gate, they will pay PAUL at another.

CORRESPONDENTS.

The late paper on the Sounds of the Heart, by Mr. E. L. Bryan, should have been dated from Stowmarket.

To the Editor.—Sir,—The person who has so long called himself Professor DEWHURST, and who has already added to his name so many doubtful titles, has now the impudence to sign himself "Fellow of the Royal Society." I have an instance before me in the "Educational Magazine," though his name is not, of course, on the list of Fellows. I should not have troubled you on this subject, had not I and many of my friends been frequently applied to by letter, by this "Professor," for subscriptions to a work, the proceeds of which he wants, as he says, to rescue him from pecuniary distress, of which he gives a terrible account. Yet, though he alleges himself to be in the most abject poverty, he figures away as "President" of a pompously named "Philosophical Society," which he announces as having many noblemen amongst its members, while in his capacity of surgeon he recommends, in "cer-

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE VIII.

HEMORRHAGE OF THE CEREBELLUM. — LESIONS OF SENSIBILITY IN HEMORRHAGE OF THE BRAIN.

IN our last lecture, gentlemen, we also touched upon hemorrhage into the various points of the cerebral hemispheres, and having discussed the functional disorders accompanying each lesion, we passed to the cerebellum. We now propose to continue the history of sanguineous effusions in this latter portion of the cerebro-spinal axis, and in so doing we would demand not only your attention, but something of indulgence and patience; we shall be compelled to enter into several details on this subject, that may appear tedious. The question which we are about to investigate has not been studied by many writers, it therefore requires a minute analysis of the cases which we have been able to collect in the records of the science; these are not numerous, our task will not therefore be very long. We are acquainted with only thirty-two published cases of hemorrhage into the cerebellum. Let us see what we can learn from a careful analysis of those cases. In investigating the substance of hemorrhage into the substance of the cerebellum we have two questions to resolve; 1st, Does an effusion of blood into this portion of the brain actually produce paralysis, as in cases of cerebral hemorrhage? 2nd, Supposing the existence of paralysis with cerebellar apoplexy demonstrated, on which side does the lesion of motility manifest

itself; have we paralysis on the same, or on the opposite side?

As to our first question, if we would decide it simply by *à-priori* reasoning, it is a much more difficult one than you might at first imagine. We are not sufficiently acquainted with the physiology of the cerebellum; experiments have not determined, in any thing like a satisfactory manner, the functions which belong to this portion of the brain; we are, therefore, compelled to rely almost exclusively upon pathological observations, and we shall presently see in what manner they resolve our question. As to our second question, whether paralysis takes place on the same side as the effusion, or at the one opposite to it, if we would determine this point also by *à-priori* reasoning, we must examine anatomical facts; and what do they lead to? To the conclusion that paralysis should manifest itself on the same side as the lesion, in cases of hemorrhage into the cerebellum, because its fibres pass to a part of the spinal marrow where there is no intersection as in the pyramids. If, then, we adopt the conclusions to which anatomy seems to lead, we should say that the loss of motion is collateral for cases of apoplexy of the cerebellum, because here we have no intercrossing of fibres; it is opposite in cases of cerebral apoplexy, because the fibres passing from the hemispheres intercross at the superior part of the spinal marrow, in its anterior pillars; however, we beg you to remember what was said upon this latter point in our last lecture, when we endeavoured to overthrow the anatomical explanation hitherto received, and to show that if hemorrhage of the cerebral hemispheres does produce loss of motion in the opposite side of the body, the reason of the phenomenon escapes our knowledge.

I have just told you that anatomical facts would lead us to conclude, that in cases of effusion into the cerebellum, the paralysis should manifest itself on the same side of the body; this, however, is far from being the case; experience demonstrates, that in a great majority of such cases the paralysis is crossed. The lesion of motility occupies the side opposite the effusion. This, as you see, is the same effect produced by effusion into the cerebrum. Let us now try to re-

solve the questions we laid down a little while ago. Let us assemble our facts together, examine and analyze them, and endeavour to ascertain some general principles, by carefully comparing what has been observed by others with the facts of our own experience.

Several of the facts which shall serve as a basis for our conclusions, are published in the fifth volume of the *Clinique Médicale*; however, many more have come to my knowledge since the publication of that work, and we can now lay before you a mass of thirty-two cases, all, observe, relating exclusively to

Hæmorrhage into the substance of the Cerebellum.

Amongst these thirty-two cases, there are only twelve which do not serve to answer the questions we have put; they are not accompanied by sufficient details, although interesting on many other accounts; thus their authors generally content themselves with mentioning "a strong attack of apoplexy," &c., but neglect to say by what modification of movement the effusion was followed, and take no notice whatever of the nature of such modification; of these twelve cases, seven refer to hæmorrhage into the median lobe of the cerebellum; six of these are related by M. SERRES in the eleventh volume of his anatomy of the brain; the other is by DAXCE, in his memoir on acute hydrocephalus, printed in the *Archives de Médecine*, January 1830. In none is any particular mention made of the state of motion in the limbs. Three other cases refer to hæmorrhage in one or other of the lateral lobes, one of these belongs to SELLIER, the other to myself; however, I only saw the patient after death; the third you will find briefly noticed in Dr. AREACROMBIE'S work on diseases of the brain, page 238; here also the effusion took place into the right lobe of the cerebellum, but the author merely says, "the patient lay in a comatose state for forty hours, and then died. He does not refer in a distinct manner to loss of motion. There remain now two cases, and in those the effusion was double, occupying both hemispheres of the cerebellum at the same time; one has been published in the *Archives Générales de Médecine*, and is given without any details whatever. The last case is related by MORGAGNI in his work "De sedibus et causis morborum." He found the individual dead, and the upper limbs strongly contracted. This is too imperfect an account to afford ground for any deductions. Hence we have only twenty cases in which sufficient details are given to allow of our comparing the lesion with its effects. They are more or less perfectly described, and we shall now examine them in succession. And, first, to determine our first question:—

Is Apoplexy of the Cerebellum accompanied by Paralysis?

What do the facts say? In the twenty cases just alluded to, we find only three in which no paralysis existed. The first of these three cases was published by M. BAYLE, in the second volume of the *Revue Médicale* for 1824, page 70. Here the lesion existed in the middle lobe of the cerebellum. The patient fell down suddenly, without consciousness, but the power of motion remained. M. BAYLE assures us, that when the patient was pinched, he withdrew his limbs with a certain degree of flexibility. Paralysis was absent, then, in this case. The individual died on the fifth day, and on the third before his death, was seized with convulsive movements of the lower limbs, and some stiffness about the region of the neck.

The second case of apoplexy of the cerebellum without paralysis, is contained in the thesis of M. MICHELET, on "colorations of the cerebral substance" sustained before the Faculty of Medicine in 1827. Here the patient, a young girl, eight years of age, had been struck with an apoplectic attack two years before her death. She had amaurosis, but no paralysis; an ancient cell was found in the right lobe of the cerebellum; however, it is right to observe, that this case is not sufficiently exact to be conclusive. The author does not say whether he had examined the patient from the commencement, at the date of her first attack. She might have been paralytic then, and have recovered the motion of her limbs. This case, then, merely shows, that at a certain period of time effusion into the cerebellum was not accompanied by any lesion of motility.

The third observation has been published by M. DROUILLAIS, in his inaugural dissertation. Here no paralysis existed, although an effusion of blood was found in one of the lateral lobes of the cerebellum. The patient died, exhibiting nearly the same symptoms as those mentioned in the case of M. BAYLE.

Thus, out of twenty cases in which the lesion of motility is described with accuracy, we find only three where motion remained intact; in all the rest, viz. seventeen, we find the existence of paralysis expressly mentioned. Here our first question, then, is answered, "Does paralysis accompany effusion of blood into the cerebellum?" Yes, certainly. Our next question is, "What is the seat of the paralysis?" The answer; Paralysis shows itself in the form of hemiplegia. Finally, we may ask, in these seventeen cases, where hæmorrhage took place into the cerebellum, giving rise to paralysis,

What was the particular seat of the Hæmorrhage?

Did the effusion occupy the middle lobe, the lateral lobe, or both together? Does it coincide more frequently with one form than

with another? Let us again examine our facts. Of the seventeen cases accompanied by hemiplegia, one only acknowledged for its cause an effusion into the median lobe. This case is reported by M. GUJOT in the journal which preceded the *Lancette Française*, in, I think, the old *Clinique des Hôpitaux*, t. 1, no. 70, page 110. In the sixteen remaining cases, the effusion was situated in one or other of the lateral lobes. Thus we have determined two points; first, that paralysis exists; second, that it exists in the form of hemiplegia; and, finally, that in seventeen cases of hemiplegia determined by effusion of blood into the substance of the cerebellum, one only occurred with hemorrhage of the median lobe, eleven of the lateral.

Again, we have here to ask a question which we have already resolved with respect to the cerebrum. Thus we may inquire if this hemiplegia, existing, as we have just shown, in sixteen cases, manifests itself on the same side as the lesion, or opposite to it; in other words,

Is the Paralysis of Cerebellar Apoplexy direct or crossed?

Let us have recourse to our facts as usual. What do we find? Of the sixteen cases, the paralysis occupied the opposite side of the body eleven times; eleven out of sixteen, crossed paralysis; two of these eleven cases belong to M. SERRAS. One has been published by M. CAZES in his thesis on paralysis, in 1824. Another was observed by Dr. CHAMBEYRON at *Salpêtrière*. A fourth case was observed in the service of M. PROBY, and published under his authority in the French *Lancet* for 1829, October 17th. Another, and one of the earliest cases, was given to the public by Dr. HUNTER, in his thesis. Finally, you will find five others in our fifth vol. of the *Cronique Médicale*. We should, however, remark to you, that in Dr. CHAMBEYRON'S case and in one of those which we have published, hemorrhage into the substance of the cerebrum coincided with effusion into the cerebellum; strictly speaking, therefore, we have only one instead of eleven cases, of sixteen which show that paralysis may occur at the side opposite the lesion in the cerebellum. We have been compelled to enter into details that may appear long and tedious, but they were necessary, absolutely unavoidable. The questions we had proposed, could only be answered by an appeal to facts. We were compelled to assemble these from different sources, submit them to analysis, and lay before you the results.

Before proceeding any further, we have to establish a division which is not without importance in the study of cerebral apoplexy. Either the cerebellum alone is injured, or effusion has taken place at one and the same time into the substance of the cerebrum

and the cerebellum. Let us take the first division and ask,

When the Cerebellum alone is compromised, can we have direct Paralysis?

a circumstance which, as you know, sometimes occurs with hemorrhage of the cerebellum. The records of medicine furnish us with only a single case of paralysis occupying the same side as the hemorrhage, in cases where the lesion is strictly confined to the cerebellum. It is published by M. TAVERNIER, in his thesis on loss of memory, sustained in July 1825. We must examine this fact with some care, as it is unique—the only exception to a rule which embraces a good many facts of an opposite kind.

The individual who forms the subject of this observation was attacked for the first time, in the year 1812, with an access of apoplexy, marked by a complete loss of motion in the limbs on the left side of the body. Eight years passed over without the recurrence of any accident. In the year 1820, the patient suddenly lost the power of motion in the right side of the body, and this time the access terminated fatally. On examining the body after death, the ancient lesion was discovered in the left side of the cerebellum. A recent clot was found occupying the middle lobe of the same organ: this latter evidently corresponded with the late attack, and was the cause of death. Here we have an example of an old apoplexy, shown by the remnant of a cyst, which gave rise during life to direct paralysis; that is, to loss of motion on the same side as the lesion. The case seems well detailed, but if we study it, we find a great objection, which in our eyes considerably diminishes its value. Thus M. TAVERNIER did not attend the patient during the first attack in 1812; the history of the case was given him by the patient's wife: it is therefore only hearsay testimony. The woman may have observed badly; she may have mistaken one side of the body for the other, as people often do: in a word, her evidence cannot be accepted as conclusive, and we must regard this case as only half a fact. We therefore conclude, that when the effusion of blood engages the cerebellum alone, the paralysis is invariably situate in the opposite side of the body; at least we are compelled to draw this conclusion, until new observations come to shake it in a more direct manner than that of M. TAVERNIER. Now for our second division:—

When Hemorrhage takes place simultaneously in the Cerebellum and in the Cerebrum, what do we observe?

We have lately seen an example of this event in disease: three others are recorded in our work on diseases of the brain. You will also find a case in the *Journal Hebdomadaire*, t. 1, page 41, and two or

three in the work of M. ROSTAN on "Ramollissement." You saw that when hemorrhage exists in the cerebellum alone, the paralysis is opposite; but let us suppose another case. Imagine a patient with a double hemorrhage, one in the left lobe of the cerebellum, the other occupying the right hemisphere of the brain; what should we observe here? Paralysis of the four limbs? Double hemiplegia corresponding to the double hemorrhage? No such thing; although the cerebellum may be full of blood, no effect is produced by it on the motions of the body. It is the brain alone which influences motion, masking, or rather altogether absorbing, the faculty of the inferior organ; assuming to itself the whole direction of voluntary movement, and thus giving rise to a phenomenon, which, though inexplicable, is worthy of the most attentive consideration. The cases published by ROSTAN and others prove this fact beyond doubt, although their authors never thought of the application when they published them. And remark, that in several cases where we have a different kind of lesion in the brain and cerebellum, as atrophy for example, the same thing takes place. Thus a diminution of one lobe of the cerebellum, which if it existed alone would certainly modify the faculty of movement, loses this power as soon as it becomes associated with atrophy of the cerebrum, and paralysis is observed only on the side opposite the injured hemisphere of the brain.

We have now passed in review hemorrhage of the cerebrum and cerebellum, together with the lesions of motility that accompany it. Let us pass to effusion of blood into the substance of the spinal marrow, or, rather, to the

Paralysis occasioned by the effusion of Blood into the Spinal Marrow.

Here the phenomenon is a simple one and easily understood, for the cause acts in the immediate vicinity of the nerves that supply the voluntary muscles. In most cases the paralysis is double, the limbs on both sides of the body are deprived of motion, and the seat of this double paralysis will naturally depend on the seat of the effusion, as the latter occupies a more or less elevated point of the chord. In some cases, however, hemorrhage of the spinal marrow is followed by hemiplegia; this is of rare occurrence; but you will find an example well detailed in the work of M. OLLIVIER on diseases of the chord. Finally, we may remark that the paralysis is never crossed, as we see is almost universally the case in hemorrhage of the cerebrum or cerebellum.

Hitherto we have confined ourselves to loss of motion as it may exist in the voluntary muscles of the limbs. It is time to consider paralysis of other parts of the body: to examine how far the other func-

tions, depending upon muscular action, are deranged by hemorrhage into any part of the nervous centres. However, we shall speak of paralysis principally in connection with hemorrhage of the brain, for the influence exercised by effusion of blood into other parts of the nervous centres, upon the muscles we now allude to, is not well understood. Let us examine each of these muscular parts according to the different regions in which they are situate, and first for

Paralysis of the Muscles of the Eye.

Paralysis of the muscles, which direct the movement of the globe of the eye, has sometimes been observed; it is, however, a circumstance of rather rare occurrence; the loss of motion does not strike all the muscles to an equal degree; hence their antagonism is lost, and the phenomenon so well known under the name of strabismus, takes place; but this symptom, we again repeat, is seldom seen in cases of cerebral hemorrhage. The eyelids may also be deprived of motion, and particularly the levator palpebrae superioris. In some cases it precedes the loss of consciousness, and the general paralysis, for a very considerable time. We call to mind one, especially, in which the patient was unable to keep his upper eyelid from constantly falling down, for three weeks before the attack.

Paralysis of the Cheeks.

Those different parts of the face, the muscles constituting the cheeks, may also be engaged, and, indeed, this happens more frequently than for any other of the parts comprised in the present series. It is worthy of remark, that the facial paralysis always occurs on the same side as the hemiplegia, a fact which we cannot explain by the decussation of the anterior fibres of the brain in the pyramids. When once established, it produces certain phenomena that are worthy of being noticed. The paralysis is most appreciable in the buccinator muscle; hence, when the patient eats, the paralysed cheek is distended passively, until the alimentary mass is removed by a purely mechanical action, and, in severe cases, at each expiration the cheek becomes in like manner passively distended, the buccinator swells with air, and when the latter is pressed through the mouth, it gives rise to the phenomenon popularly known under the phrase "funerary pipe," smoking a pipe. The want of antagonism in the muscles of the face is also the reason why the patient, when he laughs or talks with vehemence, &c., makes ridiculous grimaces we sometimes observe.

We have said that the face is constantly paralysed on the same side as the limbs. We must correct this assertion, for exceptions, though excessively rare, still exist. We have seen one case in which hemiplegia existed on one side of the body, and para-

lysis of the face at the other. This is the only case we have witnessed, and here probably the nervous centres were affected with a double lesion.

The Movements of the Tongue

are very variously modified in persons affected with cerebral hemorrhage. In the first place we observe a certain number of cases where the movements of the tongue remain intact—where it conserves a perfect integrity of motion, while the other parts are more or less profoundly injured. In other cases the motions of the tongue are imperfect; the organ at first remains immovable for a short time, and is then suddenly thrust out, after extraordinary efforts on the patient's part. Finally, in other cases, the tongue is completely paralyzed; the patient is unable to put it out; the slightest motion is imperceptible, and the organ remains lifeless in the bottom of the mouth, in spite of the most violent efforts to advance it. In this latter case language is lost, not from any injury which has been done to the organs of voice, but from want of the mechanical means necessary to distinct articulation. Sometimes the tongue is affected with only a partial kind of paralysis; the patient is able to thrust it out, but the tip deviates sensibly to one or other side. We may ask then, To which side? Answer: The deviation of the tongue is not constant; however, we may lay it down as a very general rule, that the point turns towards the paralyzed side of the body; thus, if the hemiplegia exists on the left side, the tongue deviates to the left &c. The other case is infinitely more rare; examples however exist (and we have seen more than one), where the tongue was directed towards one side of the body, while paralysis occupied the opposite membranes. The motion of the tongue is generally recovered long before the limbs begin to enjoy the faculty of locomotion; thus, it is not rare to find a patient speaking without hesitation, and complete master of his tongue, in ten, twelve, or fourteen days after the occurrence of cerebral hemorrhage, while the lower or upper extremity is still weak and motionless. In most cases, then, the lesion of motility, as regards the tongue, is much less considerable than in the limbs; there are, however, some exceptional cases; thus we have examples on record of individuals who have fallen down in a state of apoplexy. On recovering, the members remain weak, the walk is unsteady, the arms feeble, nothing more; but the voice is gone, the paralysis of the tongue is complete, and the patient is unable to articulate a single word. Now for certain other muscles.

Paralysis of the Neck

is excessively rare in cerebral hemorrhage. We have never had occasion to observe it.

When the muscles of this region are paralyzed, the head inclines towards the injured side, while the face is drawn to the opposite. Paralysis of the muscles of the larynx is also extremely rare; however, you will find a very curious example of complete aphony accompanying cerebral hemorrhage, in the work of M. MOULIN.

Respiration and Deglutition.

The respiratory muscles are not affected, except in cases of a most dangerous nature, where the attack has been sudden, and the coma supervenes with intensity, in a rapid manner. The muscular tissue composing the pharynx and the larynx is sometimes struck with paralysis, but this also is very rare. We never observed it except in severe cases, and it is generally a mortal symptom; the result of this paralysis is a difficulty, or, in some cases, a complete impossibility, of deglutition, and the prognosis, as we said, then becomes very unfavourable. In certain other cases, this difficulty of deglutition forms the prominent symptom; for a considerable time before the actual effusion into the brain, we observe no other premonitory phenomenon. Dr. FLANDIN has published a case of this kind relative to a young man twenty-eight years of age, who, in consequence of violent mental emotions, was suddenly seized with *malaise*, and impossibility of swallowing; there was no other symptom worthy of notice until the following night, when the limbs on the left side of the body were suddenly deprived of sensation and motion; the difficulty of deglutition, with the paralysis, continued unabated for thirteen days, when the former gradually abated; the hemiplegia however continued unchanged. This is a rare and curious case; it shows in how many bizarre forms nature seems to present the same injury of the nervous centres.

Paralysis of the Rectum and Bladder

has also been observed in cases of cerebral hemorrhage; however, we believe these latter accidents occur much less frequently than has been imagined; nevertheless, it is always good to be on your guard, for the urine may be retained, especially in recent cases. When therefore you have a patient affected with apoplexy, you must be careful to examine from time to time the region of the bladder, and as the patient does not enjoy sensibility, you must not only touch this region, but ascertain the actual state of the bladder by percussion. The muscular fibres of the stomach have been said to partake sometimes in the general paralysis, but this is an assertion which requires further proof before we can admit it.

Duration and Termination of Paralysis.

Once produced, the paralysis which is really the effect of cerebral hemorrhage, presents

itself with the essential character of persistence: it may last with unabated intensity to the patient's death, or it may diminish without completely disappearing, or it may at length disappear in a perfect manner. When the paralysis subsides, it generally does so in a slow and gradual manner, and this is an important fact to observe, for it shows that the lesion of the nervous centres consists in effusion of blood, and not in simple congestion, when the patient continues to live for any considerable length of time. The paralysis may persist for twenty years, or even longer, and then the limb either conserves its original form, or the nutrition of the extremity becomes diminished, and it wastes away in a sensible manner. In other cases the diminution of the paralyzed member is much more rapid. We remember one example in particular, where the limb was evidently much smaller than natural within eleven hours after the date of the effusion. The paralysis, as we have said, may gradually diminish, but still at the end of many years some modification of the motility yet remains. The limbs are not active in their movements; they feel heavy, or the fingers remain habitually flexed, &c. These permanent accidents often coincide with little or no lesion in the brain. We had occasion to examine the body of a patient affected with paralysis twenty-seven years; the loss of motion, however, had gradually diminished, and at the second attack, which proved fatal, nothing remained but a simple weakness of the limbs on the left side of the body. After death we found, in the substance of the right thalamus, a hard line, of a dull whitish colour, not more than six lines in length. This was all that remained of the ancient coagulum; recent one existed in a different point of the brain. Another division, which we established a while ago, is that in which the paralysis disappears completely at a greater or less period after the occurrence of hemorrhage. Such a case has been seen, and thence we are induced to conclude that the coagulum has been completely absorbed, and that the nervous influence is transmitted with its original force through the cicatrix, the last vestige of an ancient hemorrhage. In some cases of the kind now alluded to, even this cicatrix is removed. In others, however, we discover more or less trace of lesion, such as cysts of various sizes, &c.; and yet, long before death, all paralysis has vanished. Here, then, you see one and the same condition of the brain, in which paralysis may be absent or exist, according to individuals,—a new proof, in addition to those so often insisted upon in the commencement of our present course, that besides the morbid conditions appreciable to our senses in the dead body, there are others, equally important, which escape our anatomical investigations, but

which add their all-powerful influence to the former, in favouring or preventing the development of functional disorders.

The Disappearance of the Paralysis, in general follows a certain order.

What is that order? In most cases the tongue, the face, the lips, first recover their movements; the tongue ceases to deviate, the mouth recovers its natural form, and is no longer awry. After that the limbs regain the power of motion, and almost always the paralysis disappears more slowly in the upper limbs than in the lower. We have already noticed how members which have remained a long time paralytic lose their volume, or become stiff or contracted; but this is not all: in many other cases, shortly after the apoplectic attack, the side of the face and the paralyzed limbs are from time to time agitated by convulsive movements; one would think that the blood at once stimulates and deadens the nervous influence. In cases of this kind we have sometimes found the nervous pulp surrounding the coagulum perfectly free from any lesion that could explain the symptoms of irritation; in others we have seen the coagulum surrounded by injection of the cerebral substance, or by more or less softening, accompanied with coloration of the nervous pulp. Thus we have endeavoured to complete the history of paralysis depending upon effusion of blood into any portion of the nervous centres: it now remains to consider lesions of sensibility, and lesions of intellect, in connection with the same subject.

LESIONS OF SENSIBILITY OBSERVED IN HEMORRHAGE OF THE BRAIN.

During the course of this and the last lectures, we passed in review the various accidents of motility that present themselves, either in connection with hemorrhage of the brain, of the cerebellum, or, finally, of the spinal marrow: having disposed of this, the most important and interesting part of our subject, we shall now take up the lesions of sensibility which accompany effusion of blood into the cerebro-spinal axis.

These lesions are much less constant in cases of cerebral hemorrhage than those of motility, and much more difficult to trace to any determinate alteration of the brain. However, we must follow nature as she presents herself, although we may be unable to explain her actions: we shall therefore consider lesions of sensibility in the brain itself; in the cutaneous integuments; in the organs of sense; and, fourthly, in the different mucous membranes susceptible of being submitted to experiment. First, let us examine

Lesions of Sensibility in the Brain.

Sometimes the occurrence of hemorrhage is not preceded by any trouble of sensibility in the brain. In other cases it has

been preceded, for a greater or less period, by a few accidents connected with modified sensibility. Thus the patient is subject to a weight in the head, to cephalalgia more or less violent; he is giddy, troubled with vertigo, &c., and these symptoms frequently prelude an effusion of blood into the substance of the brain. They are, in fact, phenomena of congestion, alternating in degree, and at length terminating in hemorrhage.

Modifications of Sensibility of the Skin

we have to distinguish under two classes. We must study them, first, as they present themselves before hemorrhage has taken place; secondly, as they are seen after the occurrence of that accident. Before the instant of being struck with apoplexy, many individuals do not experience any modification of the cutaneous sensibility. This is a general rule, but admits of many exceptions. Thus some patients experience a curious sensation in the limbs: they feel a peculiar kind of coldness, as if the hands were suddenly plunged into cold water. Others complain of a pricking pain, of numbness &c., in the fingers or toes, or even in the whole of the limb. The different perversions of sensibility which we have now pointed out as preceding the effusion of blood, may exist always in the same point of the skin, or affect in turns different points of the cutaneous periphery; they may manifest themselves on both sides of the body at the same time, or be confined, as was said, to a single member, which is commonly the one which will subsequently be attacked with paralysis.

Nothing is more variable than the period of time separating the first appearance of these lesions of the cutaneous sensibility from the moment of hemorrhage; sometimes they precede the latter by a few days only; in other cases the numbness, pricking pain, creeping sensation, &c., have existed many years before the occurrence of hemorrhage. We have seen a remarkable example of the latter circumstance in the case of a woman at *La Pitie*, who, at the age of fifty-two, had been struck with an attack of apoplexy; from the age of seventeen this female experienced a sensation of creeping in one of the hands; at first intermittent, the sensations at length became constant, and shortly before the period of effusion, were joined by a similar feeling in the lower extremity, together with some giddiness and headache. Thus you see that the prodromes of this kind may be prolonged for a very great period indeed, and that in cerebral hemorrhage the attack is preceded by various disorders of sensibility; sometimes these latter are so well marked that we can even predict beforehand the side of the brain which will subsequently be implicated in the disease. Remember, however, that accidents of this kind are

rare, and that you cannot expect to meet them frequently as the precursors of apoplexy.

We now arrive at those lesions of sensibility which are observed after the effusion of blood has actually taken place. In many cases the loss of voluntary motion is not accompanied by a destruction of sensibility; the patient is unable to move, but he feels at other times that sensibility is either completely abolished, or merely modified, and in this case the modification of feeling usually takes place in the same side as the paralysis; in a few rare examples, however, the feeling becomes abolished at one side, and motion at the other. The sensibility once modified in consequence of cerebral hemorrhage, what do we observe? In proportion as we become removed from the instant of hemorrhage, the sensibility of the skin returns, and is almost universally restored, long before the limbs have recovered the power of motion. Thus, in the first few days after an attack of apoplexy, if you pinch the patient's skin, he does not evince any symptoms of feeling; in a few days more, sensation, though dull, exists; and, still later, the power of feeling has returned in the limbs, though still incapable of executing the slightest motion. The sensibility of the various

Mucous Membranes accessible to the Touch

may also be modified in a greater or less degree; the conjunctiva covering the globe of the eye is sometimes so insensible that it admits the approach and even the contact of the finger, without giving rise to any uneasy feeling; in some cases the membranes at the entrance of the naris, mouth, &c., seem much less insensible at one side than the other, and all these modifications, very various in degree and seat, seem in some measure connected with a lesion of the fifth pair of nerves. The face and lips also suffer in some cases of the above kind; in one case I have seen a remarkable diminution of sensibility of one side of the mouth and nostril, in an individual in whom the whole corresponding side of the face was also insensible.

The Organs of Sense

may partake in their turn of the general disturbance; the sense of vision remains intact in a great number of cases; however, when the attack of apoplexy is very violent, the power of seeing is frequently completely lost. When vision is troubled, the accidents may appear, either before the hemorrhage has taken place, or after its occurrence, or at the same instant that the patient is attacked. Before the effusion, some individuals experience various disorders of the sense of vision, various strange and unusual sensations, which are felt at no other time. Some are tormented at the idea of flies constantly passing immediately before the eyes; others

have a veil or fine membrane like a spider's web drawn before their eyes, covering everything with a species of cloud, as when the crystalline lens begins to alter; others constantly see a coloured object in everything they regard; nil bodies to them are painted with little red or black points. Diplopia or double vision has been sometimes observed as a precursory symptom of cerebral hemorrhage, and in some few cases this phenomenon has been intermittent; other individuals are struck with complete blindness, and this presents the most striking premonitory sign, existing nearly alone until effusion takes place; or the loss of vision may disappear and return again at uncertain intervals. Some authors affirm that in certain cases the sense of vision acquires an unaccustomed degree of sharpness before the attack of hemorrhage; we have never seen an example of this latter phenomenon. Thus you see that several functional troubles are connected with a disturbance of the brain for a greater or less period before the occurrence of hemorrhage: they show that some change, which we are unable to appreciate, but whose nature it would be of the utmost importance to determine, takes place in the cerebral pulp, or in its manner of acting, long before the lesion which characterizes apoplexy.

At the instant the effusion of blood takes place, vision may remain intact: it may be destroyed or weakened on one side or both. When the hemorrhage is very violent, vision of both eyes is generally abolished. In cases of less gravity, the power of sight may be simply weakened, or lost at one side of the body only; and in this latter case what do we observe? In some individuals the loss of vision occurs at the paralyzed side of the body; in another class it is at the opposite that the modification of sight is observed.

We have endeavoured, by a careful examination of cases, to determine whether these different troubles depend on a difference in the seat of the lesion, and although we have not been able to establish this in a satisfactory manner, it still remains probable that the diverse modifications of vision in the cases of cerebral hemorrhage we have just described, are connected with the seat of the effusion, and the influence it exercises on the various roots of the optic nerves. You know how these nerves are derived, by numerous filaments, from different parts of the brain, and, moreover, how the intersection of the two chords is incomplete; hence some fibres pass directly from the brain to the organ of vision; others, on the contrary, decussate the fibres of the other nerve, and pass obliquely to the visual organ of the opposite side; hence we can conceive, that as the hemorrhage may implicate one or more of these different fibres, the loss of vision may take place at one side of the body or at the other, and the

various modifications of this sense be in some measure explained. The observations we have just made, refer principally to loss of vision at one side of the body rather than at the other; but a more general question presents itself, viz.,

When the power of Seeing is completely abolished, can we affirm that a particular portion of the Brain is injured?

—that the lesion, that is, occupies the thalami, the corpora quadrigemina, &c.? No, certainly not; if the hemorrhage be violent and extensive, we have complete abolition of the sight, no matter what region of the brain be attacked, because in these grave and dangerous cases, the whole organ is equally compressed; however, we have cases on record which show the existence of a similar phenomenon with a small coagulum, situate now in one part of the brain, now in another. M. SERRES, to whom we owe many researches upon this point of the physiology of the brain, affirms that blindness does not occur when the lesion is situate above the level of the thalami nervorum opticorum; the effusion must take place in the optic ganglia, on a level with their commissure; but this and several other opinions of the same kind require further examination and more imposing proofs before we can admit them without reservation. It is certain that blindness may coincide with a lesion, not of the brain, but of the cerebellum; we have before drawn your attention to this interesting point of pathology: we shall not, therefore, recur to it again. We must not neglect to mention a phenomenon of the visual organs often connected with cerebral hemorrhage, viz., dilatation of the pupil; but as this symptom is merely the consequence of loss of sensibility to the retina, it comes under the same head as blindness, and may be classed under the modifications of vision.

The other senses follow the same rules as vision. The hearing may be modified either before, during, or after the effusion of blood. Many patients complain of ringing in the ears, strange noises, and various other hallucinations of a similar kind. As to the senses of smell and taste, we have nothing particular to remark, except that they also may present different modifications of sensibility in cases where the fifth pair of nerves is implicated in the lesion of the brain.

We have thus discussed the various lesions of motility and sensibility that occur in consequence of hemorrhage into the nervous centres. We have also, as you may remember, examined how far these diverse modifications of the power of motion are connected with a difference in the seat of the lesion. We might submit lesions of sensibility to the same method of examination. The sensibility of the different organs and surfaces is modified, without any nota-

bles difference, whether the lesion be seated in the brain or cerebellum. When hemorrhage takes place into the mesocephale, the cutaneous sensibility is very rapidly abolished, and the same observation may be applied to effusions of blood into the centre of the spinal marrow.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON CASES OF

DISEASES OF THE JOINTS.

Delivered in the Session 1835-6.

BY MR. TYRRELL.

LECTURE III.—DISEASES OF THE LIGAMENTS OF THE KNEE-JOINT, AND DISEASES SIMULATING THOSE AFFECTIONS.

Progress of Cases previously described.—Gentlemen, I shall to-day continue the subject which occupied my last clinical lecture, — diseases of the joints. (See LANCET, No. 644, page 528.) Respecting the four cases of fibrous capsule of the hip-joint, then described, three are well. The patients were, an elderly man, a boy, a young man, and a woman. The two patients whose cases were left for further consideration were Septimus Carter and Sophia Mouth. *Septimus Carter*, as regards the affection of the hip, seems quite well. He was here yesterday, when I carefully examined him. Pressure over the joint did not cause any suffering. He has some slight pain about the knee, attributable to a slight continuance of disease of the fibrous capsule.

The woman, *Sophia Mouth*, whose local disease I said had been retarded by ill health, is improved as regards the local disease. The secretions are better, but her health is so far from being good, that she wishes to leave. The air of the hospital does not agree with her. She is to quit to-day, but I have procured her address, and shall ascertain the progress of the case for your future information.

After these cases, I mentioned two cases of inflammation of the synovial membrane of the knee-joint, one in which an increased secretion had given rise to a puffiness of the joint, the other characterized by a diminished secretion. The first patient was well when I mentioned the case, and the second has since been dismissed as cured. There is no more to be said of prognosis, on moving either the knee or the thigh.

Next we had the case of disease of the cruciate ligament. In this the head of the tibia was attacked. The patient had been

presented as cured, so far as the disease admitted of relief—that is to say, all pain was gone, and the man was able to use the limb with tolerable freedom, the motion being a little interfered with, in consequence of the alteration of the articular surfaces.

The other case was of a rather aggravated kind, in a woman named Sullivan. The condyles of the femur were enormously enlarged, without giving way. I have seldom seen so great an enlargement without there being abscess, or more severe disease than existed in this instance. At the last report I made, she was directed to apply to and keep on the surface of the joint, the blue ointment, with soap cerate, in equal parts, adding a little opium. The subsequent report says, “the condyles are much reduced in size. There is some pain and tenderness over the lateral ligament, which pain is increased at night, but not so greatly as materially to disturb rest. The health is a little impaired. She complains of pain in the head, which might be attributable to irritation of the mucous surface of the bowels, she having slight diarrhoea, for which she was directed to take the compound chalk mixture, and a small quantity of port wine was given to her.” Two days afterwards, the report says, “the bowels continued a little relaxed, but the headache is relieved; the local affection, however, appears rather aggravated,” in consequence perhaps of the debility ensuing from the affection of the bowels. The pain was rather more at night, disturbing her rest, and she complained of some tenderness on the surface of the condyles, particularly in the situation of the external and internal lateral ligaments. In the space of the next four days, a considerable amendment took place. The general health was much improved, the pain and tenderness of the joint were less, she rested well at night, the bowels were regular, and the appetite was improved. Yesterday, the day after, I inspected the part, and was rather surprised to see the diminution that had taken place in the condyles, which is very unusual to any great extent. Perhaps the thin shell of bone had shrunk after the absorption of the internal deposit. The diminution, also, of the periosteum, which had been thickened, may have tended to account for the diminution in the size of the part.

There is mentioned in the report, “pain in the situation of the lateral ligaments.” These ligaments, in such a case, are naturally put on the stretch; for the distance of the points of attachment above and below is necessarily increased, and slow inflammatory action is thus produced. Since the condyles have diminished, the pain has altogether ceased. I expect at our next meeting to report this case as cured, so far as it is curable; that is to say, that all inflammatory action has been subdued.

CASE 1.—Disease of the Internal Lateral Ligament.—I shall to-day direct your attention to one case of disease of the ligament of the knee, and to another which has the semblance of that disease. The first is the case of Anne Fitts in Queen's Ward, aged 36, of regular habits, an inhabitant of Bethnal-green, admitted October 29th. She said that about two months ago, after exposure to cold and damp, she experienced a dull aching pain in the right knee, increased on motion of the joint, and particularly severe at night. Leeches were applied without benefit, and on her admission, she complained of much pain on the inside of the right knee, particularly in the situation of the internal lateral ligament, more severe at night and disturbing her rest. There was some pain over the whole joint, but more upon the inner side. The leg was flexed upon the thigh to a great extent, and any effort to extend it produced great pain. The muscles which flexed the leg appeared to have got into a contracted condition. I ordered her half a grain of acetate of morphia at night, and, to relieve the local affection, a moxa was applied over the lower part of the vastus internus muscle. Here you may remark, that there was a deviation from the principle which I inculcated in a former lecture. I said it was best to apply the moxa near the part which was the seat of the disease; and so it is where there is sufficient substance to admit of the eschar. The coverings, however, over the knee-joint are so thin, particularly over the internal condyle, that there would be a risk, on the separation of the slough, of the ligament being exposed, and producing a more severe form of disease. So the moxa was applied a little above it.

November 7th, the report says, her pain greatly relieved; sleeps well at night; pressure over any part of the joint is not productive of much pain; the general health remains good; the moxa discharging very little. From this time to the 20th, she made very little progress; there was rather more pain in the knee, and she was unable to extend the leg. However, she slept well, the appetite was good, and the secretions were in order.

December 2. Rather more pain in the knee, which she attributes to efforts to extend the leg. Had little rest last night in consequence of this. I desired that the moxa should be repeated, as the former had nearly closed, and, further, that instead of the passive motion from day to day, the knee should be placed on a splint, with a hinge, which, by means of a screw, could be gradually extended, and that it should be screwed out daily, but not to such an extent as to produce suffering. The application of the splint produced some pain, which lasted a very short time however, and she now suffers but little. There is but

little tenderness, and what remains is just in the situation of the internal lateral ligament, otherwise she is well. Yesterday, also, I had the opportunity of seeing her, and I was pleased to find that the leg, instead of being closely flexed on the thigh, had now got nearly to a right angle with it, and, no doubt, by the continuance of the same means, we shall eventually render this part perfectly free, that is to say, the limb entirely extended.

Remarks.—This is a common case of affection of the knee, particularly in women. The internal lateral ligament is, for an obvious reason, more liable to diseases in the female than any other ligament in the knee-joint. We find, on looking at the skeleton, deprived of the soft parts, that even in the well formed male the femur has a little inclination inwards, towards the median line, as you trace it from above to below, and that from the difference in the length of the two condyles the tibia is put nearly in a straight line, so that every person who is well formed, is slightly in-kneed. But where the pelvis is broad, as in women, and the upper part of the thigh-bones is separated to a great extent, the inclination inwards, towards the median line, the obliquity, is greater; consequently, all females who are well formed, have that particular inclination of the limb which is termed in-knee conspicuous. Sometimes this occurs to a very considerable extent. You may observe in a woman who is walking, when the pelvis is very broad, that she has a slight waddle, inasmuch as she is obliged to throw the inner condyle of one femur over the other, as she brings it forward in progressive motion, otherwise she would strike one knee against the other. This gives a rolling walk to women who have a wide pelvis, and on every occasion of forcible extension of the leg, as in running, jumping, and so forth (and it occurs also in falling), the internal lateral ligament receives the greatest stress, and is, therefore, more frequently injured, and more subject to disease, than any other ligament of the joint. Next to this the posterior ligament oftenest becomes affected, because in the extension of the leg beyond a certain degree, that ligament is put most on the stretch. There was no other evidence of affection of the knee, in the present case, further than some general pain, which, however, was trifling in comparison with that which existed just over the internal lateral ligament. The contraction of the muscles is not uncommon. The muscles are not placed so immediately about the knee-joint as they are about the hip. We have, principally, tendons passing about it, and it is curious that the triceps muscle more frequently becomes contracted than the others, which go to supply the knee. The contraction of the knee may be attributed not

so much to any morbid condition of the muscles as to the position which the patient maintains to enjoy rest, or freedom from pain. The patient, therefore, lying on the back, flexes the leg on the thigh, and suffers less in that position, particularly when the internal ligament is affected. The ligament being diseased, the moment the leg is extended the former is stretched and the pain more severe. From constantly maintaining a flexed position for many days together, therefore, the contraction becomes almost permanent, and considerable force is required to effect the extension when it has existed for many weeks or months. The points in this case, therefore, are, that the part diseased was indicated by the seat of the pain,—and the character of the disease by the pain being worse at night,—thus affecting the fibrous tissue. The motion of the joint without crepitus, showed the synovial membrane to be free from any participation in the injury. She has been cured under the simple application of small moxæ, and attention to the general health.

CASE 2.—*Affection simulating Disease of a Ligament of the Knee-Joint.*—

Harriet Winch, aged 29, a cook, residing with a family in Thames-street, was admitted into Lydia's Ward on the 4th of September. She states that about two months ago, after much exercise, she experienced pain at the posterior part of the left knee, which in a short time became so severe as to oblige her to discontinue work. She then went into the country, where, from rest and quiet, the pain left her. She returned to her situation, and in the course of two or three days the pain again attacked the knee with increased violence, and was particularly severe at night, disturbing her rest. Leeches were applied to the knee, but with little or no benefit. On her admission, she complained of a dull aching pain at the posterior and inner part of the knee, particularly towards evening and during the night. The posterior part of the joint was apparently a little swollen, and extremely tender. I found after her admission that I had been led into an error, probably from not quite understanding her description of her case. I understood that she had had an affection of the knee, applied some counter-irritant and leeches, gone into the country, and there recovered, attributing the recovery of the local affection to the application of leeches. But it appears that in stating this she referred to the treatment on the second attack, when she was an out-patient elsewhere. I should have been more careful in my inquiries when she was admitted, and should have in consequence ascertained the nature of the disordered condition of the small portions of caloric, and applied, every night, with leeches

to the knee, for the extreme tenderness, which was thus relieved for a short time, and she was cupped over the vastus internus to six ounces. This afforded little relief. She was now ordered an additional quantity of opium, and from the sensation of extreme heat in the knee, a cooling spirituous lotion was applied to it, as she thought it would be grateful to her.

On the 16th (nearly a fortnight after) the pain and tenderness were somewhat less; the rest at night was much less disturbed, the condition of the bowels and secretions was good; the uterine functions were regular. The opium was still continued, and a blister was now ordered to the knee.

23. Rest rather better at night; in other respects much the same. The former blister having healed, place another over the joint.

Oct. 6. Complaints of much pain in the posterior and inner part of the joint. Omit the opium, as it produces headache and constipation. Blister repeated for the third time.

11. The pain and tenderness less; rest at night less disturbed, but she still complains of pain in the head, which is referable to the forehead.

23. The pain in the knee greatly relieved; pressure produces but trifling suffering, but the pain in the head is still very distressing. The opiate was again tried, with a stimulant, the liquor opil, with the camphor mixture. Apply the strong blue ointment, with lint, to the knee, not to be rubbed in, but merely laid on the surface.

30. Pain in the head less, but still distressing. In other respects much the same.

Now from my inquiries, and seeing the little benefit derived from the local remedies, I began to suspect that there was an hysterical diathesis, and the local disease was continued principally from this. I now ordered her to take the compound galbanum pill, and, with this, a small quantity of hyosciamus every night.

Nov. 4. Not quite so well; the inner part of the knee continued rather tender; rests better at night, but is occasionally disturbed with pain. She was now ordered to take the pill twice a day, and upon the affected part was to be placed the soap-kerate, simply with a small quantity of opium, the blue ointment having produced some degree of superficial irritation.

11. Less pain in the knee than since her admission, but pressure over the inner part of the joint gives pain; rest at night not disturbed, and general health improved.

18. Pain in the knee again severe, and the joint tender. I now increased the power of the anti-hysterical medicine, giving the ammonia of the tincture of valerian twice or three times a day, in drachm doses.

25. Much the same. Complaints of pain in the knee, and rest disturbed at night. Frequent tremors of the limb, which last

about ten minutes, after which the pain is very much increased. Tenderness over the whole joint, more particularly at its inner and posterior parts; pain in the head distressing. I now changed the remedy, giving her the subcarbonate of iron, still, however, holding the opinion, that the affection depended a good deal on hysteria.

Dec. 2. Pain and tenderness the same; complains of throbbing at the joint; says she has occasionally extreme heat at the inner part, which continues about a quarter of an hour, followed by a corresponding degree of coldness; trembling of the limb occurs more frequently; pain is increased for a short time after the cessation of the tremors; appetite more impaired; the secretions from the bowels are extremely offensive, of a dark colour; the bowels are torpid, but the uterine functions are natural. I directed that she should have the *asafoetida* injection, about half a drachm of the common *asafoetida* dissolved in half a pint of tepid water, and injected every evening. On the 8th, after she had had one or two injections, she complained of some tightness across the chest; rest much disturbed; headache remained; altogether much in the same state. Appetite a little improved. This patient, also, for the present, will quit my care, as she is desirous of leaving the hospital to obtain country air, which, after the first attack, did all that was necessary.

Remarks.—This has been an interesting case, inasmuch as in the first instance there was every evidence of affection of the joint of a serious kind, that is to say, acute inflammation of the internal lateral and the posterior ligaments. Perhaps the situation in which the affection was described by her to exist, prevented me from inquiring so far into the history of the case as I should have done; and this combined with a belief that she had been relieved, as I said, by counter-irritation and leeches, induced me to believe that it was a case of disease of those ligaments, from inflammation, which would be relieved again by rest, and the treatment which had before been adopted. I therefore treated the case at first as declared in the report which I have read to you, and until I found that she had the nervous tremulous pulse belonging to hysterical patients, that she was frequently the subject of headache, seldom without it over the forehead, and that she had a pallid look. This, however, was a little puzzling, when we came to find that the uterine secretions were in a proper condition; but as I have seen frequently exceedingly well-marked hysteria, even in a violent degree, while the uterine functions have apparently been in a good condition, I was not so much surprised as I otherwise might have been.

Now there are further symptoms here with regard to the knee, which it may be as well to point out, that convince me the

affection is not one of actual inflammation of the ligaments, but that it is a *sympathetic affection* depending upon a peculiar condition of the constitution. If she had had merely inflammation of the internal, lateral, and posterior ligaments, the pain would have been confined to those parts particularly when the limb was at rest, and she would have complained of pain there especially on pressure; but when you come to examine the surface of the joint, it matters little where you press. If you press on the patella, on the ligamentum patellæ between the patella and the internal lateral ligament, there, or even on the vastus externus, or internus, or on the insertion of the internal muscles, or higher up, or lower down, it is all the same; she still complains of pain. It is true she complains of pain more if you press on the posterior or lateral ligaments, or on the anterior part of the joint; but supposing that had been fibrous disease, what would be likely to occur under the unimproved condition of general health? I know that the fibrous disease would have gone on. Besides thickening, we should have had ulceration taking place, and further tumefaction, an increase of pain, with general rigors, indicating the commencement of suppuration, instead of which you find that in one day's report the knee is described as being rather better, the pain less severe, and the rest better; then a day or two afterwards, without any obvious reason, the pain is aggravated, and the local disease rather increased, and the patient thus going backwards and forwards. This is not the character of actual disease of the ligaments, unless there be some peculiarity of the constitution, some apparent change, from time to time, which will enable you to account for the local alterations that take place. This case has been one of considerable interest, and it has assumed so closely the character of ligamentous disease, that I shall take care to investigate it further. I have therefore desired Mr. WHITE, who kindly assists as my clinical clerk, to take the patient's address, and she has promised to let me know from time to time how she gets on. She has gone to reside in a purer atmosphere with her parents. I have directed that she should take occasionally an aloetic purge, composed of aloes, hyssopus, and colocynth. I have given her also the compound steel mixture, with a small quantity of castor. This she is to take regularly, and I have directed her to apply to an intelligent medical man in the neighbourhood, who will modify the medicine from time to time, according to the symptoms. I trust and think that I shall be able in a short time to give you favourably of this case, and of confirming the views I had taken, namely, that the first of all, the peculiarity which is designated "hysteria" puts on the semblance of

local disease, and, again, how much the general health has to do with the continuance of local affection, whether sympathetic or real.

CASE 3.—*Complicated Disease of the Knee-Joint.*

There are two other cases in the house at present, which afford proof of further extension of disease of the knee. One is a man named Richard Gifford, a sailor, who has partial ankylosis of the knee-joint, a man of intemperate habits, aged 47. He was admitted into Abraham's Ward, on the 19th of November. He states that at about the year 1819, sixteen years since, while at sea, he received a severe blow on the outer side of the knee-joint, from the fall of a block. Much pain and swelling followed the injury. He was obliged to discontinue work, and then he obtained admission into the *Bermuda Hospital*. Blisters were frequently applied, and blue ointment was rubbed upon the surface of the joint, and under this treatment the swelling gradually disappeared. He left the hospital as cured, but there remained stiffness of the joint. From that time till about two years ago he suffered but little, except from stiffness, when the joint, without any apparent cause, began again to swell, and was very painful, particularly at its outer part. He got admission into the hospital ship, the *Dreadnought*, lying in the river, and in about three months he was discharged as well. The stiffness of the joint, however, increased, and in about two months after this the affection again came on, and then he was admitted, complaining of a dull aching pain in the left knee, not referable to any particular spot. It was much increased during the night, and on pressing the head of the tibia against the condyles of the femur, an acute darting pain was experienced, particularly at the anterior and inner part of the joint. The condyles of the femur were somewhat enlarged, and the motions of the joint very limited. There was slight power of flexion and extension. He cannot bring the limb perfectly straight, nor can you carry it far back. The pain was not particularly severe during the day; it seemed to extend up as far as the great trochanter, and along this course there was some slight tenderness. The limb was a little wasted. The secretions were natural, and the general health good. Upon examining the joint, I should say that there was evidence of there having been destruction of bone, from the deposition in those parts. The head of the tibia was rather sunk, approaching to the posterior part of the condyles of the femur. This could not have taken place without there being ulceration of the posterior ligament, perhaps of the transverse ligaments.

On the inner side the knee was found to have advanced more towards the femur; it

was very trifling on pressure upon the thigh-bone. Complaints of some soreness about the condyles, much increased at night.

29. Much the same; can bear pressure on any part of the joint, except on some part of the inner condyle.

December 2. More pain in the joints and at the inner part of the condyle; rest at night much disturbed; the appetite remains good; bowels slightly constipated, but regulated by the house medicines. Repeat the blisters. Not much alteration since the last report; if anything, tenderness rather diminished.

Remarks.—I believe that in the first instance, that, from the description given (which, however, will hardly enable us to decide accurately), he had probably had inflammation affecting the ligament and the synovial membrane. He describes the pain to have been very great, and the swelling very considerable, so that he could not continue his work. In the *Bermuda Hospital*, probably from the active treatment that was then adopted, the disease was checked before proceeding to the extent of suppuration, so as to form an aperture by ulceration. But in consequence of the destruction of ligament, of the synovial membrane, and of the cartilage, the articular surfaces became united by granulations, and then again the granulations were prevented from becoming ossific by submitting the part to slight motion. This is not an uncommon termination of diseases of the joints; rarely, however, does it reach, in the knee-joint, this termination, because when suppuration occurs, the constitution suffers so much that the patient sinks under it.

We have, however, specimens here to show to what extent the disease may go. Here is one in which you will see the joint nearly obliterated, and the condyles of the femur united to the head of the tibia by ossific matter. Here is another preparation, in which you will see the head of the tibia resting on the anterior part of the condyles of the femur. In this instance dislocation had taken place, in consequence of ulceration of the ligament, the synovial membrane and cartilages, and the man's foot had come forward, so that the anterior part of the tibia was at right angles with the anterior part of the thigh-bone. In that position union took place, even to the extent of ossification, as you will see by the preparation. Now in the case of which I have just read the particulars to you, there has been very slight alteration from ulceration, and why I say there has been ulceration is, because the head of the tibia has separated a little from the condyles of the femur. The patient lay in bed, with the limb supported on a pillow, which allowed the tibia to pass backwards. This is, however, better seen with reference to a case which I will now read to you.

CASE 4.—Inflammation, ulceration, and destruction of ligaments of the knee-joint.—

Samuel Ruffles, aged 24, residing at Blackheath, a porter by occupation, of regular habits, was admitted into Abraham's ward on the 1st of October, 1835. He states that when about seven years of age he had some slight affection of the knee-joint, arising from a blow he received at play. About Christmas, 1834, he fell with some violence on this knee, and the accident was followed by considerable pain and swelling, so as to oblige him to discontinue his work. Leeches were applied to the part, and he remained pretty well, occasionally suffering pain in the joint. At last the pain became so severe, and the joint so much swelled, that he could no longer use the limb. After some time an opening formed of its own accord by an ulcerative process of the inner side of the leg, about two inches above the joint, which gave exit to a large quantity of pus, together with synovial fluid. Upon his admission he complained of severe pain in the knee on pressure, particularly at night; the tibia was partially dislocated backwards, and the head of the tibia was also somewhat enlarged. The wound discharged a healthy pus, the limb was much wasted, the rest at night disturbed, but the general health, considering all things, pretty fair. He was desired to take the compound rhubarb powder, consisting of rhubarb, soda, and calumba, and three grains of the sulphate of quinine in infusion of roses, and he was to take half a grain of muriate of morphia, to procure rest at night, and half a pint of porter a day, and he was placed on the house diet. A moxa was applied to the outer side of the joint, the knee was to be slightly flexed, and supported on a pillow to allow the condyles of the femur to sink backwards.

Oct. 8. The moxa discharges freely; pain less; sleeps better, but slight motion of the joint produces great uneasiness.

14. The condyles of the femur appear to have recovered much of their natural condition, but still, at the joint, there is a darting pain occasionally. On the whole, the general health is improved.

21. Complained of no pain except on motion, moxa discharged freely; the wound on the inner side of the thigh produced a discharge of healthy pus. The size of the knee is diminished; rest good. I desired now that the leg should be placed on a swing box, which would give him more facility to move in bed, and at the same time allow the condyles to sink backwards.

26. Has had much pain since the leg was placed in the cradle, and but little rest in consequence. A slight swelling is traced on the inner side of the knee.

30. Suffers very considerable pain; the swelling was increased.

Nov. 2. There being fluctuation, an opening was made to give exit to a quantity of

healthy pus. This relieved the pain, the condyles of the femur still slightly project forwards, but not so much as when placed in the cradle.

11. The wound on the outer side of the joint discharged freely, no pain in the knee, pressure over the joint does not produce pain, sleeps well at night, and general health good.

18. Discharge from the wound less, in other respects much the same.

24. Is still doing well.

December 1. Is free from pain, the wound on the outer side of the joint is healed, that on the inner part discharging pretty freely; the general health remains good. A small sore is formed on the heel from pressure. On the 7th, three days ago, he was improving and gaining health and strength.

Remarks.—In this instance the case is rather more clear, showing injury at an early period of life, producing chronic inflammation of the ligament. He recovers from the first attack, and then, by further violence, gets a more severe form of it, quickly running from the adhesive stage to the ulcerative. Great swelling immediately takes place, great disfigurement ensues, the ligaments are soon destroyed by the ulcerative process, and unless care be taken, they quickly separate from their attachment, and the articular surfaces become dislocated. That has been the case in the preparation on the table, and to such an extent as to produce a deformity that would be hardly credible. I have seen several instances of this kind in which the tibia has been dislocated backwards in this way upon the femur. That could not place without destruction of the lateral ligaments, the posterior ligaments, and the crucial ligaments. At this time the disease has extended also to the synovial membrane, and the cartilages, which have been destroyed in the process of ulceration. The extent to which suppuration takes place in these instances is very various. Sometimes you will have the destruction of cartilage, of the synovial membrane, and of the ligaments, with but little apparent formation of matter, as in the case of Gifford. In that case there does not appear to have been suppuration to any extent, and no external aperture was formed, and he got rid of the severe state of the disease under rest and counter-irritation. But at other times you will find the formation of matter very extensive, as in the instance of the man Ruffles, where the matter formed in the cavity of the joint, and then discharged itself through an opening formed by nature. At this time the constitution suffered much, for when the disease proceeds to ulceration to any extent, constitutional irritation is produced of a symptomatic kind, but often of a most severe description, so that the cases we get of this kind in the large metropolitan

hospitals, more frequently require to be removed to get rid of the source of irritation to save life, than to attempt to cure them otherwise, as in this patient. When I admitted this man Ruffus into the house, there being an opening communicating with the joint, there being partial dislocation, and strength below par, I was doubtful whether I should not have to remove the leg, but he has gone on so well, under good diet and careful attention, that I have no doubt now of the ultimate favourable termination, unless the healing process is disturbed by some accident; we shall get the granulations perhaps to inoculate, and then he able to use passive motion. This will depend, however, on the closure of the wound into the joint, for so long as that wound exists, it cannot be right to use passive motion, because we may increase the injury by it. But as soon as the external wound is closed, passive motion may be resorted to, and he will then get some use of the joint, perhaps to the extent that the man Gifford has, and perhaps a little more. These cases will then show the greatest extent of disease compatible with the safety of the limb.

We have thus seen the knee-joint affected, and the synovial membrane liable to be diseased, as well as the articular extremities in their cancellated structure, and the ligaments, but more particularly the internal and the posterior, in which case the disease of the ligamentous structure extends to the synovial membrane, and the cartilages beneath become destroyed. The articular surfaces are removed, a new deposit takes place, which unites the osseous extremities of the bones, sometimes by fibrous matter and sometimes by osseous matter. These cases, which proceed to an extreme degree, rarely do well, in consequence of the difficulty of maintaining sufficient power in an atmosphere like this, but the cases I have cited are exceptions to the general rule. I have not at present any other case of interest of this kind in the house, and as we have now followed this subject up in three lectures, I shall go to another subject when next we meet.

A TABLE, published in Dr. Lombard's work on the influence of professions on pulmonary consumption, shows that, of all the circumstances enumerated, the most injurious to the lungs is the inhalation of animal and vegetable emanations, which pollute the air of localities. Next, but at a great interval, come bodies floating in the air. Next, the most active causes in the development of consumption are, the want of regular exercise and habitual residence in a malarious district. In the fifth place comes the want of clothing, the trades which require to be performed, or great motion of the arms.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON A CASE OF

SIMPLE FRACTURE OF THE LEG,
FOLLOWED BY GANGRENE.*Delivered in the Session 1835-36.*

BY MR. GREEN.

THIS morning I shall address to you, gentlemen, some observations on a case of simple fracture of the bones of the leg, which was followed by gangrene. In a case that was admitted on the 6th of October last. The patient was Charles Hayling, aged 47, a flour porter, of good stature, and muscular, though not bulky. He had been a gin and porter drinker; latterly, however, only taking porter on account of a cough. I do not know, however, whether, to cure the cough, he took the porter, or left off the gin, but he had had a cough for some time. In other respects he said he was temperate in habits, and not accustomed to intoxication. While standing on the step of a door, a brewer's dray was suddenly pushed back, and jammed his right leg between the wheel and the step. He was immediately brought to the hospital, where it was found that the tibia and fibula were fractured, with comminution, at about the middle of the leg. There was considerable effusion around the seat of the fracture, and a small wound on the outer side of the leg, not however communicating with the fractured portion of bone, so that the injury came within the description of what is termed a *simple fracture*. There was also some grazing of the skin; and a remarkable fact is stated by Mr. TREW, under whose care the case came. No pulsation could be felt in either of the tibial arteries at the ankle. Now this, in connection with the subsequent circumstances, is a fact worth notice. The knee was half bent, and placed on the side, and, though there was not much bruising, on account of the swelling and tension, the leg was wrapped by Mr. TREW in flannels steeped in hot fomentations. The bruising I was informed was not very considerable, though there was so much swelling and tension as to render it advisable, in Mr. TREW's opinion, to apply fomentation by warm flannels.

In the evening of the next day, the 7th of October, he complained of great pain in the limb, and appeared rather delirious, wishing to get out of bed, and speaking sharply and rather incoherently. Still his mind was easily recalled, and he answered questions very satisfactorily. The limb had become much more swollen, and the discoloration

was increased, both above and below the fracture. There is also some swelling about the knee; the foot is cold, and much less sensible than natural. Fifty drops of the tinctura opii were given to him in the evening. Thus we already see that on the very day after the accident, a change had taken place, which was very unfavourable. You will observe that the sensibility of the foot had become diminished, and the power of sustaining its natural temperature was much lessened, and that this was accompanied with constitutional irritation; at any rate some disturbance of the nervous system had occurred, which was to be regarded as an unfavourable sign.

The circumstances bring to my mind the case of a man, which indeed has been published, with a compound fracture, in which at the end of about ten days, when the patient seemed to be going on favourably, violent hemorrhage took place, and it became necessary to amputate the limb, though the condition of the patient was very unfavourable. Indeed, stimulants were essential to bring him to bear the operation, and yet its necessity was absolute, for the loss of a very small quantity more of blood would have destroyed the patient, as we could not get at the artery. The patient being of a healthy and robust frame, and the loss of blood apparently the only cause of the depression, I injected several ounces of blood into a vein at the bend of the arm, and the man, in consequence, revived uncommonly, took nourishment, and seemed to be going on well; but on the next day he altered and was sinking. I repeated the transfusion, but without any effect. The first untoward symptoms were, restlessness, and a desire to get up, but he was easily quieted; still when left to himself his mind wandered. What change could have induced the latter symptoms which he exhibited? It turned out afterwards, that mortification had occurred on the face of the stump, and I do not in the least doubt but that it was this which caused the first symptoms, and also prevented the second transfusion from producing good effect. The mortification may have been partly the effect of the great loss of blood reducing the powers of the system below the requisite condition to sustain vitality, followed by the infliction of such an injury as amputation. Mortification of the stump took place, which we failed to overcome.

To return to the case before us. The foot was observed to be cold. Opium was given in the evening, and it was thought well to envelop the whole limb in a poultice.

Oct. 8. The patient is much easier. The opium had produced him a quiet night. Bowels regular; his general health unaffected. Perhaps you will think this rather too strong an expression after hearing that the pulse was 110; however, the appearance

of the man justified the remark. His countenance was good, his complexion bright, his lips and eyes were natural, and he said he was very comfortable; so that I apprehend that some who may have stood by his bed, might, when his limb was covered up, on simply looking at his countenance, and hearing him speak, have said there was really nothing the matter with him.

The report goes on to state that his pulse was 110, rather full, and not wanting in power; tongue clean; skin warm and moist; perfectly sensible. The peculiar wandering has gone off; it was a very remarkable symptom. The leg is now more discoloured, as if it had been severely bruised. The foot exhibits many large patches, and a bluish red colour on a perfectly white ground. There is œdema about the ankle, and much tumefaction about the lower third of the thigh. The skin of the thigh is very hot, but not discoloured. The superficial veins of the thigh are remarkably charged. There is still the same want of sensibility in the foot, and an absence of pulsation in the tibial arteries. It short it became perfectly distinct that gangrene was taking place to a considerable extent; but it was remarkable that the system generally bore the injury so well. It seemed at that time scarcely to have taken the alarm. It is remarkable, I mean, as an unfavourable symptom, for very commonly you will find that where the system does not take the alarm, when there is sufficient cause for alarm, there exists some cause which is likely to interfere materially with the patient's recovery. It has been noticed, — and I think there is some ground for the observation, though it is difficult to come to any very decided conclusion upon a point where the instances must take place under such varied circumstances that one cannot feel justified in generalizing with great confidence, — but it has been observed that persons who do not complain much at the time of undergoing an operation, but bear it apparently perfectly well, often do very ill afterwards. This fact seems in some degree to bear upon the case now before us. Here was a patient in whom, although there was quite sufficient cause, from incipient gangrene, for violent irritation of the system, yet the system seemed to be unaffected. I saw him on the 8th, which was the third day, and I well remember, as mentioned in the report, that while the appearance of the limb was gangrenous, his general health was unaffected.

Well, I had to make up my mind as to the treatment. Although, in some respects, of a favourable constitution, yet the man had, beyond doubt, been far more addicted to the use of spirituous liquors than was calculated to render him a particularly safe subject for the consequences of such an accident. Here was a patient, however, connected with a constitution, and an opinion

sider two things; first, whether, under any circumstances, it would be proper to amputate at this period; and, secondly, whether, considering that in this particular case there was gangrene, and a destruction of parts to follow, which it was scarcely possible he could survive, yet his general health being still unaffected by it, whether, by removing the source of irritation by amputation, we might not prevent the subsequent derangement, and the probably fatal constitutional effects which were likely to arise without that operation? I might say that a third point presented itself to my mind, which, though it did not bear very importantly on the treatment in connection with the other two questions, yet is worthy of notice, and that related to the cause of the gangrene. The limb was so jammed by a cart-wheel as to produce a severe contusion; and there was a good deal of swelling after the accident, but still, according to the report of the appearance of the leg immediately after the accident, it did not appear even probable, still less certain, that the gangrene was entirely produced by the local injury. There was no appearance, on admission, of the parts being so crushed as certainly to evidence the cessation of their vitality. Therefore, the question might very well be asked, What was the cause of the gangrene? Doubtless, the bruising was one cause; but it seemed probable that there was something more. One naturally asked then, Is any main artery so ruptured as to cut off the supply of blood? I called your attention to the fact, that there was no pulsation in either the anterior or the posterior tibial arteries; but if, for instance, there had been rupture of the popliteal artery, that might have explained the want of pulsation in the arteries at the ankle, but not, with certainty, the occurrence of mortification.

I recollect the case of a young gentleman, who, in riding a race, struck his knee against a tree, and fractured both bones of the leg. The limb immediately began to swell, and so continued until it was swollen to a prodigious size. The surgeon in attendance was utterly at a loss to account for this extraordinary swelling. The patient was treated in the usual way, and after the usual lapse of time at which a fracture might be supposed to be united, it was found that the union had not taken place. He was placed on Dr. AMESBURY'S fracture apparatus, but with no better success, the swelling did not subside, the fracture did not unite; inflammation, suppuration, and abscess, supervened; then came on a bleeding, and then it was necessary to amputate the limb. And the cause of this was ascertained to be a rupture of the popliteal artery, very close to the fracture, which was probably produced by the violence of the blow. Now gangrene

known one or two other cases of ruptured arteries where gangrene did not supervene. Nature may fully provide for the supply of blood to parts when arteries are ruptured, by anastomosing branches. But there was no pulsation in this case in the tibial arteries. How came that? Was there any coagula in those vessels, the consequence of the severe blow? I am not acquainted with any facts which will warrant such a supposition in such a case, but there is a preparation on the table, taken from the Museum, in which you will observe a clot in the brachial artery; and I recollect having heard Sir ASTLEY COOPER speak of this case as one in which the mortification of the limb (for the arm mortified in this instance) was supposed to be dependent upon the formation of that clot; but I do not know any further particulars of the case than those which I have detailed to you. We may readily suppose that where an obstruction to the circulation takes place by means of a coagulum, an insufficient supply of blood will be distributed to the parts below, and that obstruction may be the cause of the mortification.

But no such circumstances were found to exist in this case; there was no rupture of the artery, no coagulum, no little specks of coagula here and there, as you might have expected. The vessels were empty; nothing obstructed the circulation, nor was there any thing in the history of the case, or in the after examination of the limb, sufficient to explain the very interesting and important fact, supposing it to have been accurately ascertained,—and I do not doubt (considering what Mr. TAYLOR has stated) that it was thoroughly ascertained,—that there was no pulsation in the tibial arteries. Whether that was connected with the gangrene, in the relation of cause or effect, I am unable to say.

Let us return then to the questions; First, Would it have been proper to amputate under any circumstances? Secondly, Whether in this particular instance it was proper to amputate at that time.

With respect to the first of these questions, surgeons, I think, are still in some doubt whether amputation should be performed (gangrene having taken place) before a line of demarcation occurs. Most of them have agreed to wait for that line of demarcation, in opposition to the opinion of the older surgeons, that amputation is a remedy against the spreading of mortification. Indeed, I think ample experience has shown that if you amputate during spreading gangrene, under ordinary circumstances, mortification of the stump generally takes place, and you gain nothing by the operation. But, certainly, we do not want cases showing the propriety of operating at another time, and there are individuals who have adopted the opinion that where mor-

tification arises purely from local causes, and is dependent upon circumstances entirely within the part, you may amputate before the line of demarcation has occurred. Instances might be adduced where this plan has been successfully resorted to. Thus in a man who was admitted under the care of Sir ASTLEY COOPER, mortification had taken place from aneurysm in a vessel of the arm, and Sir ASTLEY amputated without there being anything like a line of demarcation. There was a case of simple fracture in this hospital, in a maniac, who, being troublesome here, was sent to the parish house, but with the arm properly bandaged. But he succeeded in removing the splints, and mortification took place. Amputation was there had recourse to while the gangrene was still extending; and it did not reappear in the stump, but the man did perfectly well. Taking all things into consideration, we may perhaps say, as a general rule, that it is proper to wait until the line of demarcation has shown itself; while, at the same time, there are certain cases where you may amputate previously, supposing the mortification to arise from a cause which is entirely within the part and only relating to that part. Have a care, however, that the exception which you make to the general rule shall be perfectly in point.

And now, to come to the next question, whether, in the particular case before us, amputation should have been performed, although the system was not affected, and although the mortification might have been referred to the precise spot implicated. But I was very much in doubt whether the mortification could be referred solely to the local injury, and I am inclined still to think, though the issue of the case is before us, that such was not the case. The man was a great drinker, and perhaps, though I have no means of exactly determining the point, some alteration had occurred in the state of the large vessels. He certainly did not appear to have any disease of the heart, yet there might have been such an alteration there or in some of the large vessels as would produce a change in the circulation. It therefore appeared to me exceedingly doubtful, to say the least of it, that the mortification depended solely on the local injury. However, his appearance on admission being good, and not such as indicated that mortification was pending, I considered that we should give him a better chance of recovery by waiting until the parts should be in such a state as would allow the amputation to be safely performed, so far as regarded the prospects of healing, and until such symptoms appeared as would render the operation imperative, but which did not exist at the time I was considering these matters.

On the 9th of October I found that he was not so well, and had lost his appetite.

He had slept tolerably well during the past night, except when disturbed by shooting pains in the leg; the limb was more generally bluish, and a part of the skin above the injury presented rather a reddish hue, as if there was some token of separation. On the outer and back part of the limb there were several small vesications containing serum. The bluish appearance gradually subsided into the natural appearance, upon the thigh. The tumefaction had not increased, but the swelling extended to the upper third of the thigh, and there was a curious sensation in the femoral artery, as if air had been diffused through the cellular tissue. The other parts of the thigh had a doughy feel, but did not pit on pressure. Pulse 108, rather jerking, but not capable of sustaining pressure. The tongue was slightly coated; the bowels were regular. I omitted to say before, that as his habits had led me to infer that his strength could not be supported without his accustomed stimulant, I ordered him four ounces of gin daily, and full diet, directing the dresser to watch for any febrile symptoms, and then diminish the quantity of both, in order that the actions of the system should not be roused into tumult.

On the next day the quantity of gin was ordered to be increased to six ounces, with a little port-wine mixed in sago or gruel. I think it makes a great difference, whether stimulants are mixed with food or not. In food they do not seem to exert the same influence in rousing the action of the heart; they do not have the immediate effect of diffusive stimulants, for they are not then so concentrated.

On the 11th it appears that he had slept well during the former night. He was without any appetite. The state of the limb was not much varied. The foot was more bluish, but had some little warmth and sensibility remaining. The leg was dark blue. The thigh was emphysematous, and rather bluish; pulse 104; tongue whitish; bowels relieved last evening.

12. The report states that he did not sleep last night, in consequence of much sharp pain extending down to the foot. There is considerable vesication on the leg, on the outer side especially; but little sensation below the ankle; the swelling of the thigh has increased since yesterday, and now extends to the groin; the whole is emphysematous; no line of demarcation; pulse 100; tongue clean; bowels regular; skin comfortable; appetite good. I thought that advantage might be gained by using some other stimulant, and five grains of the carbonate of ammonia, five minims of the tincture of opii, and fifteen minims of the tincture of hyoscyamus were ordered every three hours, after a good sleep.

13. He slept tolerably well; gangrene

more diffused, but no distinct line of demarcation; the crepitation has increased; pulse 108, full, and tolerably firm; tongue whitish. Ordered a mutton-chop daily.

14. I made to-day three incisions, each about two inches in length; one on the front, one on the outside of the leg (both through the living and the dead skin), and one on the outer side of the thigh, in consequence of his having experienced a good deal of pain, which seemed to me to originate very much in the tension of the parts. I also thought it probable that there might be some matter or sloughs under the skin.

15. Much relieved from pain by the incisions, and feels better. The line of separation has commenced on the outside of the leg.

16. Had no sleep last night, from great pain in the middle of the leg. There is a slight sensation of fluctuation just behind the middle of the leg. I passed a lancet deeply into it, but no pus escaped. The discoloration of the leg had not extended; pulse 108.

17. Passed a good night, but his constitution is now beginning to suffer. The cheeks have a patch of pink on them; skin hot and dry; tongue dry in the middle, with moist edges; pulse 116, full, and irritable; bowels open. He has become thinner, but is in less pain. The separating line is still proceeding. The leg, just below the knee, is extremely sensible when pressed upon, and the emphysema now spreads over the whole front of the thigh, which is more swollen.

18. Much the same; pulse 118, jerking. The lower part of the leg is now quite black. An irregular line marks the boundary of the gangrene.

19. Slept tolerably well last night, and is in less pain, but his features are beginning to shrink, and there is more hectic flush upon his face; pulse 120; pain diminished; and the line separating the living from the dead parts has slightly commenced. There is a plentiful but thin discharge from the thigh.

20. The separating line is now quite distinct; he slept very well last night, but his powers are beginning to flag; pulse 120, jerking, and very easily compressed; bowels regular; appetite impaired.

21. He wandered much during the night, but towards morning became sensible, though his manner is rather hurried; he is decidedly worse than he was yesterday, and the friends were determined to amputate, as being the only chance of saving his life.

22. I now found the appearance of separation much more marked, though not even at that time presenting a distinct line of demarcation. The operation had taken place, and the separation was not complete. The limb. At this time it was quite evident that his powers were decidedly sinking, and perfectly ob-

vious that they were unable to carry him through the process of separation of the limb. Accordingly the amputation was performed at 2 o'clock on the 21st. The skin and cellular tissue at the back of the thigh were full of adhesive matter, and glued firmly to the fascia. Pus escaped on cutting through the muscles. There was rather more venous blood than usual lost, and he became rather faint. Brandy was administered, but he appeared sinking. Three ligatures were applied, and a strap of adhesive plaster was used, *pro tempore*. He was taken to bed and a drachm of tincture of opii was administered. I remained with him for some time after the operation, for he certainly was in a state of complete depression from the operation. It was evident that the system had received a very severe shock, and though the quantity of blood lost during the operation was not very great, yet I apprehend that it was very sensibly felt. There was one symptom which you will often see in persons who have lost a good deal of blood, an anxiety about the breathing, as if there was a difficulty in filling the lungs, a restlessness, a turning from one side to the other, a gasping with the mouth, and, withal, considerable depression. However, I left him, with directions that he should be supported as far as possible. Diffusive stimulants were given *ad libitum*, in order to keep the powers of the system going until, if it was possible, a reaction might take place, and some symptoms of restoration should appear. At seven o'clock, having taken brandy twice, he was still very low; the pulse was very quick and weak, but yet he rallied after each administration of the brandy-and-water. The stump had been dressed, and there was but little oozing from it. Still, notwithstanding all these means for rousing the system, he died at half past nine o'clock on the same evening, without having exhibited the slightest appearance of reaction, although by that time he had taken nearly half a pint of brandy. An attempt was made to give him forty drops of the liquor of opii in a camphor mixture, a short time before his death, but only a very little of it could be got down.

Then came the examination of the limb, but I am sorry to say that there was no examination beyond that. I wished to look at the heart and great vessels, but the friends would not allow it. It was found that a triangular portion of the tibia had been detached and driven backwards, being in close connection with, though not pressing on, the posterior tibial vessels. Three inches below that, the bone was surrounded by a considerable portion of lymph. The arteries on being slit open appeared to be healthy, and contained but little fibrine. The muscles on the other side of the leg also seemed to be healthy. The fibula was fractured obliquely, immediately below the outer mal-

leolus, a considerable way below the fracture of the tibia. On cutting into the knee-joint, bloody matter escaped, and the cartilaginous substance was a little disorganized.

Could any other plan of treatment have been adopted in this case, with a better chance of saving life? Was any thing omitted which could have contributed to his recovery? Really, on reviewing the circumstances, I am not aware that a different plan could have been adopted. The man was intemperate; he had received a severe contusion on the leg, accompanied by fracture; and, apparently, partly from the contusion, and partly, perhaps, from the state of his circulation, induced by his habits, gangrene occurred. Had amputation been performed when first the operation suggested itself, the probability is that gangrene would have taken place in the stump, or that the patient would have died from the effects of the operation, as he did at a later period. The plan of treatment consisted in supporting, without rousing to tumultuous excitement, the powers and the functions of the system; and they were tolerably well sustained until the parts began to separate, when the aspect of the case was not at all favourable; and although the line of demarcation from adhesive inflammation, had never been completely formed, the actual separation of the dead from the living parts only took place partially, and, in the course perhaps of a few hours, the patient began to pass into that state which Mr. Hunter so expressively called "symptomatic of dissolution" produced under an overwhelming injury. Under these unfavourable circumstances amputation was performed, when it could no longer be delayed, but, unfortunately, the state of the system during the amputation, combined with the shock of the operation, produced the unsuccessful result which we have to regret.

DIAGNOSIS OF DISEASES OF HEART.

ON PALPITATION, NERVOUS, PLETHORIC, AND SYMPTOMATIC.

By JOHN FOSBROKE, M.D., Physician to the Royal Dispensary.

THIS is so prominent a symptom of affections of the heart, that the physicians of yore lumped together all diseases of that organ under the term "palpitation," just as I have known some modern professor or other doctor relieve himself from all manner of perplexity, by conferring the title of "Morbus Cordis" upon every puzzler that came before him. Our approaches to pre-

cision in the knowledge of diseases of the heart have not been very ancient. Dover says, that the old apothecaries, who "always described diseases in the fashion of the day," said it "at one time, that every body died of polypus of the heart, but being laughed out of the polypus, mortification of the bowels came in fashion; and, when a patient was dead, the surgeon was paid to make out the disease incurable." Dr. Parry will stand high in the estimation of the profession, so long as that man is considered the greatest physician who collects the most facts, and reasons best on those facts; but he blended together hypertrophies and dilations under the general term "enlargement," giving here and there some distinctions between the two in the course of description. Mr. Abernethy went nearer to the wind, and knew, in a general manner, the two brief differences of thickening and dilatation, and attempted to distinguish these, and almost all diseases of the heart, by the pulse. I remember him, in his striking and facetious lectures, talking of "aggrandizement of the heart's substance, being attended with aggrandizement of the heart's action, a pulse vibrating like a cart-ropes, and increase of the heart's bulk by dilatation, with diminution of its action. Where the action is increased, the heart is enlarged in its diameter, the carotids pulsate, and both those arteries are dilated, to carry off the quantity of blood forced upon them. Ossifications, strictures, and contractions of the annulus venosus, are attended with an extremely weak and quick pulse. And for why? the arteries are fully supplied with blood! Because it cannot make its way through the contracted heart. They interfere with muscular power, diminish the heart's contractions, and give rise to a pulse scarcely to be felt, and to pain in the part." (*M.S. Notes of Anat. Lect. on the Heart, by J. F.*) So talked Mr. Abernethy, and practitioners continued for some time to discriminate diseases of the heart through the pulse, like the Chinese, who pretend to discover all diseases through the same medium. I apprehend it is no better guide in the one case than the other.

Beddoes says, that John Hunter did more for the advancement of medical science, than the whole University of Edinburgh, from the time of Monro and Allen to his day, and, if he had had more of our and fewer Oxford prejudices, he might have said, than all the medical corporations and schools in Great Britain.

Since Hunter, the French have advanced farther in his footsteps, than those eminent egotists in England who have been his pupils, and have his name always on their lips. It was reserved for the French to throw a broad beam of light on the anatomy of the heart, and to draw the line, with beautiful precision, between hypertrophy

and dilatation, and to show their various causes, combinations, and distinguishing characters. "The French," says Dr. Haighton, "attend very much to, and connect very accurately, the symptoms and pathology of diseases; and, generally speaking, their diagnosis is at comparison better than ours; but they seem as if their only object was to find out the disease, without any reference to its relief or cure, for their treatment of disease is most miserable." Truly enough, their treatment of acute disease has been miserable, comparatively, with our own, but they have had different institutions, and, since the ridicule of Molière, strong prejudices, to deal with. In this respect they appear to improve every day, and in the treatment of chronic diseases, I am disposed to think they are advancing beyond us in the extent, minuteness, and correctness, of their therapeutical experiments. But, whether our inferiors or equals in treatment, they have supplied ourselves and all Europe with that whereof we lacked most grievously. "Among physicians, equal in other respects, those who are brought up to distinguish internal affections with accuracy, must always be superior. There is almost as much difference, in the cultivation of this fundamental talent, between some of our schools and that of Paris, as between the chemistry of Glauber and that of Lavoisier. Such a foundation being once laid, the proper structure may indeed not be raised upon it. But no other foundation is fit to receive the edifice of medical knowledge; without it, the superstructure must be both irregular and unsubstantial" (*Dr. Boissier*).

It appears to me, from what I saw when I was studying at Paris, and from the tendency of the clinical observations in their publications, that they so much value the study of "organic medicine," by which they mean diseases arising from changes of structure, that they pass over the more numerous diseased actions which depend merely on changes of function, as almost unworthy of regular application, because they are more uncertain, bewildering, and conjectural. In this country, we are bound to attend to them, because they form the chief part of our practice. Medicine means, in England, the "Sick Trade," and the pride of science is nothing in comparison to the pride of money-getting. Mere physiological demonstrations form the staple of this trade, and men explain them in books by a hundred different theories; and sometimes a man, by spinning a cobweb, containing scarcely an iota of truth, catches fools enough to make a fortune. I think that the French are actuated too much by the spirit of organic medicine in their inquiries into diseases of the heart. They look too exclusively at organic changes, thickenings, dilatations, obstacles, &c., and pass over, too

indifferently, the morbid action which accompanies those effects, and arises from the influence of the circulating and nervous systems. My object is, therefore, to show how disordered vascular and nervous action affect the heart in both organic and functional disease.

I observed, in the last communication, that there were three kinds of palpitation, the nervous, the plethoric, and the symptomatic.

The original cause of nervous palpitation is, that the heart is the organ of the most universal sympathy (*John Hunter*). Irritability is variously bestowed, and variously appointed, in various parts of the body, but in all creatures the heart is the most irritable part (*John Bell*). It is the first organ that receives morbid impressions from the brain, when that organ and the nervous system are disturbed by the mind, or by physical causes. It is the part most directly connected with mental emotions. (*Dr. Haighton and Blundell, Notes of Physiological Lect., by J. F.*) What is more familiar than the different degrees of irritability and irregularity of the heart's action, which are produced by profound and protracted emotions of anxiety, grief, and despondency, or what more common than the sudden suspension of every commotion of the circulating system, and the return of a calm and placid state of the whole frame, when the influence of the depressing passions is removed?

The plethoric kind arises from the influence of the blood. Inasmuch as muscles are irritable in proportion to the supply of blood, and deprived of irritability, and even paralyzed, by the want of it (*Dr. Haighton and Blundell*), the heart, as it is supplied with a greater quantity of blood than other muscular structures, is endowed with the principle of irritability in a greater degree. Secondly, as the blood is the proper stimulus of the heart and the heart's action, it may be over-stimulated by the excess of its own blood (*Mr. H. Cline*). Thirdly, according to some, the exciting power is relatively increased, not only in proportion to quantity, but quality; that is, in proportion as the blood is fibrinous, as the clot is more than the serum (*M. Andral*).

The original cause of the third kind, or symptomatic palpitations, is the existence of any disease of the heart itself, or of any organ whatsoever, near or remote, capable of opposing an obstacle to the circulation (*Prof. Rostan*), or exciting sympathetic irritation of the heart. Alterations of the heart will often depend on impressions made by remote organs; in irritation of the brain, its motions are accelerated (*Prof. Macartney, MS. Notes of Pathological Lect., by J. R.*); it is liable, indeed, to be affected by derangements of the most minute structures,

for its sympathies are most extensive. (*Prof. Alison. MS. Notes of Clinical Lect., by J. F.*)

How are these three kinds of palpitation to be distinguished from one another? In so far as we are capable of discriminating them, it will generally happen that we shall be able to discern functional derangement from organic disease of the heart. Some may regard palpitation as a matter-of-course symptom; but upon a thorough knowledge of it, upon a comprehensive view of the several kinds, and upon a clear distinction between such as have a nervous, vascular, or symptomatic origin, not only an equal knowledge of heart cases must turn, but the practice also must frequently depend. Common nervous and symptomatic palpitations are of every-day occurrence; but are there not cases of mixed nervous and plethoric palpitation, which assume the characters of hypertrophies and other organic affections of the heart? and is it not a chief point to know all modes of distinguishing them. "for it is a great matter to be able to say whether there is any structural disease or not?" (*Dr. Macintosh.*)

I. Nervous palpitations have been great stumbling-blocks in the way of discriminating organic from functional derangement of the heart. Pathologists inform us that we shall know them by the following signs and circumstances:—

1. They are most readily excited in persons of a nervous and sanguine temperament (*Dr. Macintosh*); in persons subject to extreme mobility, of nervous and debilitated habit, and therefore in women more than in men (*Prof. Home*); and in young, nervous, and irritable persons of both sexes, in particular states of the brain and its connections (*M. Rostan*); in fact, in hysterical females, hypochondriacs, and persons called nervous (*M. Martinet*).

2. Under all these circumstances of constitution, sex, and age, the usual exciting causes of the disturbance of the nervous system and of the heart, are, moral affections, intellectual labour too long continued, losses of all kinds (*M. Rostan*), the excessive indulgence of various passions, stimulants, violent exercise, excessive depletion, the participation of the heart in the general disordered nervous action of the system in hysteria, chlorosis, and epilepsy (*Dr. Macintosh*); so that the principal causes are, mental or cerebral excitement, depression, or irritation.

3. They happen to persons who have experienced other nervous phenomena (*M. Rostan*).

4. They are at first slight and transient, and are at last reproduced more frequently by the heart becoming more irritable (*Dr. Macintosh*). When, owing to a particular state of the brain and its dependencies, they are augmented by moral causes, they are only instantaneous, they produce no

profound alteration of health, and they supervene almost suddenly (*M. Rostan*).

5. The pulse is quicker than natural, from 84 to 96 (*M. Laennec*).

6. They are frequently most distressing when the body is in a state of repose, during the first part of the night, and often prevent sleep for many hours (*Same*).

7. There is sometimes a sensation of internal agitation, particularly in the head and abdomen; and, as in hysteria, the urine is copious and limpid (*Same*).

8. They are less troublesome, when the patient is taking exercise in the open air than at other times (*Same*).

9. The sound of the heart's contraction, though clear, is not heard loudly over a great extent of chest (*Same*).

10. Palpitation is without impulse; that is, "the head of the auscultator is not sensibly elevated, and by this circumstance it is distinguishable from the increased motion and shock of hypertrophy (*Same*).—This is a doubtful observation.—J. F.

11. They are known by the absence of the signs that accompany diseases of the heart (*M. Rostan*).—Doubtful again.—J. F.

12. Palpitations not depending on organic disease, more frequently affect the auricles than the ventricles, and the right auricle than the left (*Professor Home*).

I shall endeavour to show in what respects these phenomena, whether derived from the history of cases or stethoscopic signs, are true, or more or less equivocal. But beforehand, I shall state what constitutes that kind of palpitation which I have termed the "plethoric" in contradistinction to the "nervous."

Palpitations, in general, independent of organic disease, have been considered by most pathologists "a purely nervous affection." *Dr. Macintosh* observes that though he has never been obliged to open a vein or apply leeches, he "can readily imagine a combination of circumstances, which will render the one practice or the other advisable: for instance, in a young plethoric person, who is affected at the same time with some febrile movement." I have before observed that this notion of palpitation being so universally "a purely nervous affection," has been carried too far. I have seen enough to convince me of their arising frequently from vascular engorgement of the cavities of the heart. I have also seen a double cause operating in the same case; a plethoric state of the heart blended with disordered nervous action. But those physicians who have compiled books on the practice of physic, have glanced at the distinction between the nervous and plethoric kinds. *Dr. Parry*, who was a very profound and logical inquirer into the diseases of the heart and circulation, saw that they arose from accumulations of blood in the cavities of the heart; and in cases attended

*with pain in the left arm, resembling angina pectoris, he conceived that the existence of palpitation was a proof of the disease not being angina, but one of those anomalous affections which originate from blood being so accumulated. But he considered that the effect of the excess was not always the same. The first and most obvious consequence was to stimulate the healthy heart to inordinate action, which, after a time, was liable to be followed by a proportionate diminution of action, whence syncope and even death might ensue; on the other hand, another and immediate effect of such accumulations was to induce a more sluggish action of the heart's frequency and force, which has been observed in persons of full habit, and in the subjects of angina pectoris, during the time that the accumulation is produced by muscular exertion. He ascribed these two opposite effects of the same cause, to the difference of predisposition caused by different local causes,—fatness, extenuation or flaccidity of the muscular substance of the heart, ossification of the coronary arteries, or mechanical pressure on the brain, and certain narcotics, predisposing to torpor and retarded action of the heart,—to organic causes, as preternatural enlargement,—to acute causes, as inflammation, vascular fulness of the substance or internal membrane of the heart,—to chronic causes, as the irritability arising from want of bodily exercise, or, as he terms it, “defect of due exertion of the voluntary muscles,” predisposing to inordinate action. To this last and most important observation he adds that the predisposition to over-excitability of the heart from fulness of blood, “accompanies that condition of constitution which is usually called ‘nervous,’ in which the heart is peculiarly disposed to be affected by the whole train of mental emotions.”

Several cases which I have seen of late, and more especially the very important circumstances in the two by no means familiar cases of Gwynne and Howls, which will be given, fully bear out these two last important and correct propositions. They shed much light on the origin of palpitations, inflammation, and enlargement of the heart, and they bear out the evidences which I have had of mixed nervous and plethoric palpitations existing in the same case. Reitan observes that where there exists no organic lesion, a plethoric state sometimes causes palpitations more or less strong. Professor Home has noticed their concurrence, in plethoric or inflammatory diathesis, and the necessity of treatment by blood-letting and low diet. M. Martinet also distinguishes palpitations arising from plethora and congestion of the heart, and lays down a system of treatment. Professor Andral, with the accuracy which belongs to that consummate pathologist, has had a clear insight into this matter. Under the influence, he

remarks, of a plethoric state, more blood being formed in the economy, and, consequently, a greater quantity being passed through the heart in a given time, an excess of action, and palpitations, may result from it, which may either disappear with the plethoric state, or, if they persist, at last produce hypertrophy, on the same principle that any muscle whatsoever will increase in thickness under the influence of violent exercise. Adding much more than this, he gives a striking case in a blacksmith, and points out what is exceedingly important, the manner in which vascular engorgement may be confounded, through the identical character of the signs, with enlargement of the heart from thickening, now known by the barbarous term hypertrophy. The forthcoming cases will illustrate these as well as other points. The more I have seen of plethoric palpitation, the more obvious has become its importance in connection with diseases of the heart, for the ultimate effects of such forms of palpitation do not always stop at mere palpitation. Dr. Parry ascribes to undue accumulations of blood, those anomalous affections of the heart which resemble angina pectoris. “Pain in the chest, more especially in the left side, stretching into various parts of the left arm, is common to all diseases in which blood is unduly accumulated in the cavities of the heart; and if, during the paroxysm, this motion of the heart is excessive, both as to force and frequency, producing what is commonly called ‘palpitation;’ that circumstance shows the disordered state to be of a different kind from that which constitutes angina pectoris.”

Pathologists having seen angina (which above all other affections exhibits the tendency of the heart to spasmodic action) prove fatal without any organic lesion whatsoever, have decided that these changes are not the real cause. Indeed, we see preparations enough of ossifications and other structural changes, in museums of morbid anatomy, which were not only not fatal, but not indicated by symptoms during life. Professor Macartney thinks that no man has ever died yet of organic disease of the heart alone, but from morbid action supervening on morbid structure. Even death by ossification does not occur till the heart is excited, and morbid action added. No part, he observes, is so liable to be affected through the medium of the nervous system, by the mind, or the stomach, which throws light on the success of Mr. Abernethy's practice. (*Notes of Pathological Course, by J. F.*)

With these impressions, some pathologists regard even angina to be frequently the effect of “general plethora,” or, as Dr. Hosack of New York thinks, of “disproportionate accumulation of blood in the heart and large vessels;” or, in the words of

Dr. Forbes, who coincides with Dr. H., "a congested state of the heart and large vessels." Even Dr. Parry, in tracing out the causes and characters of angina pectoris, in a first-rate specimen of strong reasoning and critical powers, did not attribute the disease entirely to the effects of ossification of the coronary arteries, for he distinctly states that the symptoms show that accumulations of blood about the heart and large vessels, take place (*Dr. Macintosh*).

II. Plethoric palpitations may be known more or less by these circumstances:—

1. They are excited or increased by every kind of motion or exertion, especially by lifting the arms and exerting the chest, by ascending stairs and acclivities, and doing whatsoever hurries the blood through the heart and lungs.

2. They are increased by cold, moist, and foggy weather, or whatever produces chill of the body, and so forces the circulation from the exterior to the interior vessels of the body.

3. They are more persistent than nervous palpitations, and occur by day as well as by night.

4. They are often accompanied by pain and weight of the arms, and particularly of the left arm.

5. They are sometimes attended with throbbing and fulness of the vessels of the head and neck, and pressure about the throat and ears, particularly in going up ascents.

III. The third kind of palpitations, or *symptomatic*, are said to be of a more temporary nature than the nervous or plethoric (*Professor Graham*). They originate from the participation of the heart in the affections of every other organ, and exhibit the morbid influences to which it is obedient under undue excitement (*Dr. Blundell*). They accompany—

1. *Pericarditis*, in which both the palpitation and dyspnoea merely indicate sympathetic irritation of the heart (*M. Andral*).

2. *Adhesion of the Pericardium*. Mr. Hunter was of opinion, that when adhesions take place between the pericardium and heart, the patient generally recovers, but is troubled with a palpitation, irregular pulse, oppressive breathing, faintings, debility; and the name of angina is generally affixed to these symptoms; but if the inflammation of the pericardium approach to the suppurative process, it produces death. (*Mr. Hunter, MS. Notes of Lectures, by T. Creaser, M.D.*) Mr. Henry Cline, who paid much calm and patient attention to diseases of the heart and circulation, also thought that fluttering, from the frequency of the pulsations or contractions of the heart, with intermission of the heart's action, denoted inflammation of the pericardium, and adhesion of it to the heart. (*MS. Notes of Lectures, by J. F.*)

The late Dr. Baillie thought that adhesions

in the bag of the pericardium were often cause of an intermission in the pulse. Dr. Armstrong says he had seen several instances of such adhesions without intermission, and thinks that Dr. Baillie was mistaken. Neither of these parties was altogether right or altogether wrong. Every symptom is equivocal, and occurs in other affections of the heart, and therefore the existence of such a cause can only be detected from the history of the case.

3. *Pressure of fluid in the pericardium*.

4. Chronic enlargement of the heart, whether *hypertrophy or dilatation*, distinguished by the signs peculiar to those affections.

5. *Ossifications*. Sometimes, but not in variably, a cause.

6. *Maladies of the aorta*.

7. *Pneumonia*. Known by the symptom peculiar to that disease.

8. *Serous effusion into the pleura*. Singularly detected.

9. *Phthisis pulmonalis*. I shall refer to cases on this point.

10. *Accidental tumours developed in the lungs, or in the course of the great vessels*. Also a case in point.

11. *Ascites and encysted dropsy of the ovary*.

13. *Hemorrhages or excessive bleeding*. The palpitations are excessive, but the beat of the heart, though precipitate, is not strong.

13. *Hysteria*. On this combination I shall speak hereafter.

14. *Chlorosis*. So also on chlorotic palpitation.

15. *Hypochondriasis*.

16. *Amenorrhoea*. I shall give cases, illustrating particularly the "turn of life."

17. *Leucorrhoea*.

18. *Repressed cutaneous affection*.

19. *Biliary engorgement and liver affections*. A common cause.

20. *Enlargement of the thyroid gland, or neck vein*. Noticed by Dr. Parry.

21. *Affections of the stomach and bowels above all other causes*.

22. *Gout*. Noticed by Dr. Armstrong.

Symptomatic palpitations owing to each of these different causes, are known by the signs of those maladies of the heart from which they originate; and, if they do not originate from the heart, by the absence of all the signs of structural disease of the heart (*M. Bowdler*). It is certainly a very great assistance in diagnosis to bear this in mind; but it is not invariably easy, and the most comprehensive knowledge of cause to boot, to detect the affection of which palpitation is symptomatic. Each of the classes of causes in connection with palpitation is a study of itself. The difficulty is increased when more than one of these causes is combined, and when indeed, two, if not all three kinds of palpitation, are complicated together.

I have prefaced some cases and abstracts of cases, by laying down general principles

In the foregoing manner, that their application to those cases, and their treatment, may be the better understood. What I wish to show is, not the structural and mechanical effect of enlargement of the heart by thickening of its walls, or dilatation of its cavities, contraction of its orifices, and disease of its valves, but the influence of morbid action through the nervous and circulating systems, both in organic and functional affections of the heart, which I think is either overlooked, or merely alluded to here and there, by pathologists.

Ross, Jan. 9, 1836.

CASES AND ARGUMENTS

ADDUCED TO PROVE THAT "GONORRHOEAL RHEUMATISM" IS

COPAIBA RHEUMATISM.

To the Editor of THE LANCET.

SIR.—I should feel obliged by the insertion of the enclosed remarks in your excellent Journal. I am, Sir, your obedient servant,

FRANCIS EAGLE.

29, Poultry, Jan. 12, 1836.

CASE 1.—May 1, 1834. I was sent for to visit Mr. C. H., who was labouring under a severe attack of rheumatism in the left leg. There is tenderness at two points only—namely, at the anterior superior spinous process of the ilium, and along the dorsum of the foot. He gave the following history of his complaint:—

About two months since, having contracted a gonorrhoea, a friend prescribed for him a mixture of cubebs and copaiba, which he took for rather more than a week, when he experienced a severe attack of pain similar to the present. He discontinued the copaiba, and, with the aid of warm clothing and mild aperient medicine, got rid of the pain in a few days, and again had recourse to his copaiba mixture, when, on the following day, having a return of pain, he suspected that the copaiba had, to use his own expression, "something to do with it." He now left it off for a week, and the pain subsided as before, but on again taking the copaiba mixture, the pain for a third time returned. Fully convinced in his own mind of the connection of the copaiba with the return of the pain, he determined to try other remedies for the gonorrhoea, and resorted to them with partial benefit for some weeks. Being, however, very much annoyed at the long continuance of the disease, he consulted an eminent surgeon, at the same time stating his objection to take copaiba in any form. His objection was overruled, and a compound copaiba

mixture prescribed, which he took accordingly, but on the very day following, having taken but two doses, the pain in the leg and thigh returned with increased violence, accompanied by considerable fever and general biliary derangement, which compelled him to keep his bed, in which state I found him.

The treatment now adopted consisted in the local application of leeches, and the administration of mild aperients to improve the chylopoietic viscera, and although the pain had affected the parts for some weeks, more or less, my patient was perfectly well in sixteen days, and up to the present date has experienced no return.

CASE 2.—A young man, aged 27, messenger in a fire-office, whose habits of life were far from abstemious, perceived, on the morning following a debauch, a discharge of yellowish matter from the urethra, and immediately applied to a surgeon for advice. A copaiba mixture was prescribed for him, of which he took a dose three times a day. On the second day, however, all discharge having vanished, he discontinued its use, and went to bed rather unwell. During the night he awoke with considerable pain immediately under the left scapula, and on the following morning applied to me, when I at once advised the application of twelve leeches to the part affected, to be followed by a warm bread-and-water poultice, at the same time directing my attention to the state of the stomach and bowels, which were out of order, and in five days he returned to his office.

Remarks.—The belief that the rheumatism arising during a gonorrhoea is a specific disease, requiring a specific remedy, is, if I mistake not, founded upon a very shallow foundation—1st, that because it arises during gonorrhoea, it is gonorrhoeal; 2ndly, that it is curable only by mercury.

At page 210 of Dr. Titley's work on "Diseases of the Genitals," speaking of this disease, he says, "That this form of disease sometimes, though rarely, occurs during the continuance of a gonorrhoea. The pain and swelling are more especially confined to the knees and ankles, though, in some instances, the symptoms are more diffused, the pain is more acute, and the general disturbance of the system more violent. It is usually not until gonorrhoea is on the decline that these symptoms supervene, though, occasionally, they have appeared to follow a sudden cessation of the discharge produced by the use of cubebs or copaiba. There is often much puffiness and tenderness of the ankles, especially towards evening. The skin is not externally red, and the pain is not much increased on pressure; the pulse is quickened, the stomach becomes disordered, and the appetite declines, or altogether fails. Occasionally it happens that all these symptoms are suddenly relieved by

an eruption of papulae, in clusters, or, sometimes, of pustules, in very minute patches. When these appear, not only are the pains relieved, but the constitutional symptoms also yield; and the eruption, after some days, though sometimes not for many weeks, grows paler, and a desquamation succeeds, leaving a slightly discoloured state of the skin, which gradually subsides."

It is a fact worthy of considerable attention, that two of the most careful observers of disease, Mr. Hunter and Mr. Abernethy, but especially the former, who devoted much time to the study of the venereal disease, in all its forms, should have made little or no mention of gonorrhœal rheumatism. This fact appears in a still more striking point of view, when we consider that they scarcely ever, if ever, adopted the copaiba method of healing the disease; while Sir Astley Cooper, Dr. Titley, and others, staunch advocates of the copaiba system, have devoted considerable space to its nature and treatment.

The preceding extract from Dr. Titley's work, is an accurate description of what may fairly be called "copaiba fever," followed, as it so often is, by an eruption peculiar to that medicine, and by no means confined to its administration during a gonorrhœa. The circumstance of this form of rheumatism occurring during a gonorrhœa is, it is true, a coincidence, and may be nothing more; for, unless it be proved that it arises very frequently where no copaiba is administered (against the opposing evidence), it is fair to doubt its existence as gonorrhœal rheumatism.

Copaiba produces derangement of the intestinal canal, fever, and cutaneous eruptions. All this it does commonly, whereas gonorrhœa not once in a thousand cases produces either of those effects.

But even admitting that this form of rheumatism is a consequence of gonorrhœa, what explanation can be given of its production? Does it arise from sympathy? Or does it arise from specific venereal irritation, which its curability only by mercury would seem to imply? And if so, why is it not followed by secondary symptoms?

I assume the position, then, that the rheumatism occurring during a gonorrhœa, is, in very many instances, a production of the remedy, and not of the disease; that it is "copaiba," and not "gonorrhœal" rheumatism, upon the following grounds:—

1. Upon the preceding cases, and their daily occurrence.

2. Upon the fact that it arises during the administration of copaiba in other diseases.

3. That while it is proved that copaiba produces intestinal derangement, fever, and cutaneous eruption, commonly, such consequences of gonorrhœa, in the abstract, are extremely rare.

4. That if the copaiba be withdrawn,

where the rheumatism appears, the latter affection generally subsides immediately.

5. That if the copaiba eruption follows an attack of rheumatism, the rheumatism almost immediately subsides.

6. Upon the absence of any notice of the matter by Hunter or Abernethy, who did not adopt the copaiba system.

7. Upon my own experience, that while this form of disease frequently arises during the treatment of gonorrhœa by copaiba, in cases treated upon the soothing system it is extremely rare.

FEEDING, IN A HORSE, AFTER

LOSS OF THE ENTIRE TONGUE.

Related by M. CAILLEUX, in the Memoirs of the Veterinary Society of Caltrados.

A HORSE, belonging to the 4th regiment of HUSMARS, was very difficult to groom, so the soldier who had to manage him, fixed in his mouth a strong chain of iron, deeply serrated. Another man held the ends of the chain, and giving it a terrible jerk whenever the horse was rebellious; sawed off the tongue completely at its base, and it fell to the ground. Much hemorrhage did not follow. The portion of tongue detached was four inches and a half in length, and the disunion was effected at the frenum, or precisely at the point which separates the base of the tongue from the free portion of it. My first thought was to destroy the animal; but the interest which every one took in him, on account of his power, and his docility in every respect, except when he was groomed, and the desire to ascertain how he would feed himself when the useful part of the tongue was taken away, encouraged me to endeavour to save his life. Having stopped the bleeding, I kept his mouth constantly open with a gag, which I could extend or contract at pleasure; and I frequently injected cold barley-water, sugared and honied, and deprived the animal of every kind of food. On the third day I thought the wound sufficiently favourable to allow him a little barley-meal and water. He plunged his head into the feed half way up to the eyes, and then by means of the strongest inspirations, and sucking up a very little at a time, he contrived to empty the vessel. I then made him a paste, of bran and barley-meal, which he attacked it with avidity, seized a portion of it between his lips, and seemed astonished that he could do no more with it. I therefore renounced for a while this mode of feeding him, and contented myself with rendering his barley-water more nourishing by increasing the quantity of the meal, and stirring the mass well while he was drinking

ing it. In this manner he was fed during three or four days; at the expiration of which period the wound was healed.

I now presented him afresh with the kind of mash which I had before made, and I remarked that he set himself to work more gently in order to eat it. He kept his head constantly in the manger, and, having gathered between his lips a small portion of the food, he pressed it against the bottom of the manger so as to force a part of it into his mouth. He then gathered another portion, and, subjecting that to the same kind of pressure, the first pellet was forced somewhat further backwards; and so he continued, until, bit by bit, it was pushed on to the back part of the mouth, and swallowed. This was the work of a long time, and proceeded very slowly, but by degrees he was able to dispose of the whole of his feed. During the time of his repast he was in a profuse perspiration, showing the difficulty which he found in satisfying his appetite.

This continued during three months, when it occurred to me to mingle a few grains of oats with his barley-meal and bran. At first the oats were swallowed without being masticated; but, by degrees, mastication returned. At length he began to eat with less difficulty, and the profuse sweat with which he used to be covered, disappeared.

This kind of food, convenient enough for a horse that does no work, did not accomplish our purpose: we wished to restore him again to the ranks, and to fit him for that, it was necessary that he should have more substantial food. I gave him some hay, at first in small quantities at a time. He took it in the same manner that he had been accustomed to manage his mash; he gathered it together with his lips, and formed it into a kind of pellet with his lips, and then pressing it against the bottom of his manger, he gradually forced it sufficiently far into his mouth to be enabled to seize it with his grinders, a new pellet constantly pushing on those that were before. It was fifteen or twenty days before he could manage this cleverly; and then, being kept apart from the other horses, he was able to manage the whole of his ration. Oats were, as before, mingled with his mash, and their quantity was gradually increased, while the hay was proportionally diminished, until he was fed at the same time, and in the same manner, as the other horses belonging to the regiment. As to chaff, he could not manage that, and it was not given. His former condition returned, he now does his duty as before, and is in perfect health. A similar case to this I do not recollect to have seen. I did not expect to succeed at all; but its fortunate result induces me to publish a case which, I think, will be interesting to my professional brethren.—*Veterin. Jan.*

JERVIS-STREET HOSPITAL, DUBLIN.

TREATMENT OF FRACTURES OF THE LEG AND THIGH BONES OF CHILDREN WITHOUT SPLINTS.

[The following remarks were made by Dr. WALLACE, on going through the above hospital, on Thursday, January 7]:—

This case of fractured thigh, gentlemen (in a boy fourteen or fifteen years of age), is worth your attention. The fracture exists where the upper joins the middle third. I shall treat it without splints. It has been my practice to treat fractures in the legs and thighs of children for more than ten years without splints, and I have never had occasion to regret the plan. Deformity never, I may say, occurs, and even when it does, a very few weeks see it removed. When I commenced this plan, some of the routinists cried out, "Oh, what a shame to neglect the patient in such a manner!" They little knew the object in view. I do not believe, however, that I have ever before adopted the practice in so old a person as this. I am induced, on the present occasion, to give it a trial, not only from the results of my own practice in younger cases, but from finding in a paper by Mr. RADLEY, published in *THE LANCET* a short time ago, that this practice has been by some persons lately applied to the fractures of adults. I confess that I should be tardy, in general at least, in going so far, because, if any deformity resulted, it would not be so likely to disappear afterwards. This is the source of my opinion as to the propriety of treating fractures in growing persons without splints, while I would not treat those of older subjects in the same manner. See! how this boy lies. It is the manner in which children, who have got fractured thighs, always lay themselves. You see he is on the left or fractured side, the leg bent a little on the thigh, and the thigh on the pelvis; and he lies with his abdomen half turned round to the surface of the bed, his sound lower limb being thrown to the right, and his elbow and fore-arm, of the right side, thrown on and supported by the bed. Now, he will lie in this position until he begins to feel strength in his limb, and then he will instinctively begin to move, and exercise it through the bed, in proportion to the strength which he acquires. I have very frequently noticed, in treating the fractures of very young children, that they allow the splints to remain on, and submit, if they do not hurt them, with great gentleness to their restraint, until the bone has acquired some strength, and then they begin to be weary of restraint, will not allow the hand-ages to remain quiet, will be found constantly to fiddle with them, and will thus keep them loose. In fact, if you wanted to keep a child's

arm, which had been fractured, longer in splint than was necessary, you would scarcely succeed in doing so. The child, by its constant perseverance to remove restraint, would conquer. In treating fractures of the thighs in children without splints, I have never found that the attendant complained of any difficulty in the removal of the patient discharged.

CURE OF LUPIFORM SYPHILIS (A COMPLEX FORM OF THE VENEREAL DISEASE) WITH THE HYDRIODATE OF POTASH.

Here is another case deservng your attention. It is a case of the disease which I call "lupiform syphilis." This name expresses its origin from the venereal poison, and the resemblance which it has to lupus. Its remarkable characters are, its occurring in subjects who have not only had the venereal disease, but who have taken mercury in large quantities for it, and its commencing by tubercles, which pass into ulceration, and form groups of holes, which, sooner or later, heal, while others are formed in their neighbourhood, or on other parts of the body. Mercury will generally dry them up, but they soon break out again. For this form of disease there is no medicine which acts with the same certainty as the hydriodate of potash. You have at this moment in the hospital two other cases, those of *Free* and *Holland*, which demonstrate the great value of this medicine in this form of complicated syphilis. I will make these cases the subject of a clinical lecture. The man whom you see before you commenced the hydriodate of potash yesterday morning. Bring me the tests, and let us examine his urine. You see how it is already loaded with the medicine. He could have taken only half a drachm of the salt since yesterday. It is remarkable how soon the presence of this medicine can be detected in the urine, and how soon it escapes from the body when its use has been omitted.

CONTRACTION OF THE FINGERS AFTER DIFFUSE INFLAMMATION OF THE FORE-ARM.

Look at this case. It is a case of diffused inflammation of the fingers, hand, and part of the fore-arm. It has already formed matter and sloughs in the subcutaneous tissue. There were some incisions made in it yesterday, and you see with what great advantage; observe how much better it is to-day. I fear, however, that it will not end very satisfactorily. The patient is a very old man, and, besides, the sheath of the flexor muscles appears to be much engaged, and even, perhaps, the flexor muscles themselves are so; for, you may remark, all the fingers are bent towards the palm of the hand, and cannot be straightened. A permanent state of flexion of the fingers is

not an unfrequent consequence of diffuse inflammation of the front of the forearm. Whenever this is threatened, the greatest care should be taken to keep the fingers in a state of extension, not only until the sores are all healed, but for many weeks after. We have not unfrequently seen patients who from a neglect of doing this, have returned to the hospital with contracted hands many weeks after they had been discharged apparently well. You may remark how frequent diffuse inflammation is at present. This, you know, is one of its characters. Another of its characters consists in it either occurring in a limb without any evident cause, or from some very trifling cause. You see this illustrated in the present case. The patient says that it was caused by his burning, in a very slight manner, the end of his thumb, by touching some hot body,—a degree of injury which, probably, under other circumstances, would have produced no other effect than a state of painful itching for a few minutes.

NEW METROPOLITAN UNIVERSITY

A MEMORIAL, of which the following is a copy, has been presented to the Minister by the teachers of the *Blenheim-Street School of Medicine* :—

"The teachers of the School of Medicine in Blenheim Street, founded by the late Joshua Brookes, F.R.S., have hitherto abstained from making any representation to his Majesty's ministers respecting the projected establishment of an university in London, because they believed that the new institution would be founded upon the basis of the public good, and therefore governed by the strictest rules of justice and impartiality.

"But in consequence of the uncertainty which prevails with regard to the intention of the Government, and considering that this has given rise to rumours of an injurious tendency, and lest their silence be construed into indifference respecting the high interests involved in the question, they offer it to be their duty most respectfully but earnestly to request that all the schools of medicine at present recognised, and hereafter to be established, be placed upon a fair and equal footing under the new university.

"They submit that equal knowledge, evinced by the pupils ought to be rewarded with equal honours, no matter where, or by what means acquired, and that no advantages ought to accrue to any particular schools or classes of teachers, except the reputation derived from the manner in which the pupils acquit themselves at their examinations; unless the competency of the teachers is to be fairly tried in a public

concur, at which all their titles to distinction may be impartially investigated; and by either of these tests or modes of competition, the teachers of the Blenheim-street School are content to be judged.

"From the nature of the medical profession, the difficulty of obtaining evidence that leads to a just decision as to the comparative ability and merits of those engaged in it, and the consequent difference of opinion necessarily entertained respecting their qualifications, perhaps the only mode of appointing the Examiners and Professors of the Faculty of Medicine at all satisfactory, and calculated to prevent all invidious feeling, is by concour, a mode adopted with so much benefit to the public in France, and to which the advancement of medical science in that country is mainly attributable.

"The advantages and details of this plan, the teachers of the Blenheim-street School of Medicine solicit the opportunity of laying before his Majesty's Ministers, in any way that may be deemed expedient. Confident that were it adopted in the new University, they would have to congratulate the Government on the formation of an Institution, which would prove a source of prosperity and happiness to the country—a real and lasting blessing to mankind."

LYNN SELF-SUPPORTING INSTITUTION

FOR THE SICK AND HURT.

To the Editor of THE LANCET.

SIR,—In consequence of the prompt and handsome manner in which you noticed a former communication on the subject of our Institution, I am requested by the Members of the Board of Management, to transmit the following statement of facts.

The Lynn Self-supporting Institution has now been established two years, and I am happy to add, has fully answered our most sanguine expectations. The industrious working classes are delighted with it; and although it does not, perhaps, sufficiently remunerate the practitioner, yet it pays him better than parish practice. It must also be remembered, that through this plan, many persons contribute something, who never did anything before. But putting aside all consideration of advantage to the profession, and looking only to the effect upon those classes for whose benefit it was instituted, we have much reason to congratulate ourselves on the great improvement that this Institution is gradually working, both in the moral and physical conditions of the labouring classes.

Among the many advantages of this In-

stitution, the following deserve to be mentioned. It enables the industrious man, by a very small weekly payment, not only to ensure prompt and efficient aid for himself and family, in case of sickness, or accident, but it gives him the privilege of choosing his own medical attendant! It has also the happy tendency of raising the working man from a state of dependence and degradation, to one of independence and self-respect, thus surpassing all Institutions purely eleemosynary, which, from the nature of their constitution, can never effect this most desirable result.

Should any of the numerous readers of THE LANCET be desirous of establishing a similar Institution, I can only say that a copy of our Rules and Regulations shall be at their service; and I confidently depend upon your powerful aid in disseminating any information which has a tendency to counteract the baneful effect of the old dispensary system, which I verily believe has been the means of degrading, and of ultimately sending to the workhouse, many individuals, who, without such temptation, would have remained industrious and useful members of society. I remain, Sir, your very obedient servant,

JOHN TWEEDALE, M.D.,

President of the Board of Management.

Lynn, Norfolk, Jan. 9, 1836.

P.S. Permit me to avail myself of this opportunity to express my admiration of the cordial and disinterested co-operation of those general practitioners of this town, who so willingly have lent their aid in this novel undertaking, which, in the outset, presented many difficulties without any certainty of adequate remuneration.

J. T.

* Dr. Tweedale will confer a favour on the Editor by forwarding to THE LANCET OFFICE, at an early period, a copy of the rules and regulations to which Dr. T. has referred.—ED. L.

NONPAYMENT OF MEDICAL WITNESSES AT CORONERS' INQUESTS.

To the Editor of THE LANCET.

Reading, Jan. 9, 1836.

SIR,—A short time since I attended a coroner's inquest on a poor man, to whose assistance I had been summoned as the nearest practitioner. His friends being unable to defray the charge, I applied for payment to the Board of Guardians, a copy of which application, together with their reply, I subjoin.

Surely, Sir, this injustice to our profession cannot longer exist. I earnestly trust that Mr. Warburton will succeed in obtaining an Act of Parliament in the ensuing session,

securing to us a fair compensation for attendance in similar cases. Should you concur with me in the expediency of calling the attention of the profession to this subject without delay, an early insertion will oblige. Your obedient servant,

GEORGE MAY.

"To the Board of Guardians of the Reading Union.

"Reading, Jan. 5, 1836.

"Gentlemen,—I take the liberty to remind you that some time since I made a demand of one guinea for attendance on the inquest of — Taylor, and at a subsequent personal interview was favoured with your assurance, that the case should be reported to the Poor-law Commissioners, and that your decision would be guided by their opinion.

"I take leave to recall your attention to the subject, and should you determine to refuse my claim I hope I shall not be deemed presumptuous in requesting a statement of the Commissioners' opinion, as you will perceive that not merely this particular claim, but the interests of the medical profession in similar cases, are involved in their decision. I have the honour to be, Gentlemen, your obedient humble servant,

"GEORGE MAY."

"To George May, Esq.

"Reading Union, Jan. 7, 1836.

* Dear Sir,—I have to inform you that the Board of Guardians, in conformity with the promise they gave you, made application to the Poor-law Commissioners for instructions for their guidance in respect of the charges of medical men for attendance upon coroners' inquests, and I am directed by the Guardians to transcribe for your information the reply of the Poor-law Commissioners to that application:—

"The Poor-law Commissioners for England and Wales have to acknowledge the receipt of your letter of the 19th inst. (December), and with reference to your inquiry upon whom it devolves to defray the demand of medical men for attendance upon coroners' inquests upon the bodies of paupers, the Commissioners desire to state that they are wholly unacquainted with any authority under which the payment of witnesses at coroners' inquests, or indeed of any other expenses attending inquests, can be charged upon the poor-rates.' I remain, dear Sir, your obedient humble servant,

"THOS. G. CURTIS,

"Clerk to the Board."

* * * The members of the profession will do well to remember that their speedy personal applications to Members of both Houses of Parliament, will have a material effect, in the approaching session, on the decisions of the Legislature, with regard to the subjects discussed in the foregoing letters.—E.D. L.

TUNBRIDGE-WELLS CONTRACT.

REPLY OF MR. WAY TO MR. SOPWITH.

To the Editor of THE LANCET.

SIR, will you oblige me with an opportunity of correcting a misstatement in last week's LANCET, in which I am personally concerned, under a promise that I will not again so trespass on your indulgence.

Mr. Sopwith in his communication to you has stated, that I called upon him (*being one of the Committee*) for the purpose of pressing him to attach his signature to the Resolutions of our Association, and on his refusal so to do that, I told him that the consequences would be, exclusion from medical societies, and objection on the part of medical men to render him assistance in cases of emergency.

I regret that Mr. Sopwith should have made these observations, as he was putting a false and unfair colouring upon the whole transaction.

It is true that I called upon him with the view of obtaining his signature, from a desire that, in a matter alike interesting to all, there should be unanimity in the expression of our sentiments. It is also true, that I did represent to him (but upon his repeated request as a friend so to do) the possible consequences of his refusal to act in concert with us. But, Sir, Mr. Sopwith has omitted to tell you that in this interview I did most distinctly disclaim any authority as a member of the Committee, to communicate with him, and gave him as my motive for so doing (and for its sincerity at the time I can most truly vouch) a desire that he should avoid the unpleasant position in which, as a young man, just entering on his professional career, he must be placed by such refusal. With my conduct at the time, he appeared satisfied, and actually thanked me for the trouble I had taken. This explanation was again rendered to Mr. Sopwith at a second meeting of our Association, upon his referring (*much to my surprise*) to the subject, before the whole of my professional brethren present, to all of whom it seemed satisfactory. As to a refusal to afford him assistance in cases of emergency, though Mr. Sopwith would imply much more, all that was intended to be conveyed by me was, that he could not expect, in his absence from home, that courtesy which is usually given and received by medical men.

Having entered into this explanation solely to remove the stigma which was so evidently intended by Mr. Sopwith to be cast upon my character, I will only beg to add, with respect to the other statements in that gentleman's letter, that considering myself merely as the medium through which the communications from our Association

were made to you, I do not feel called upon individually to reply to them, though I may, perhaps, be allowed to say that they are equally misrepresented, and, if worth the time and attention, equally capable of being satisfactorily explained. I am, Sir, your very obedient servant,

W. WAY.

Tunbridge Wells, Jan. 11, 1836.

DUTIES OF MASTERS AND APPRENTICES.

To the Editor.—Sir,—The letter from a "Licentiate of the Apothecaries' Company," published in the number of your interesting and valuable journal for December 12, bears on a subject of no minor importance to the many individuals who make choice of the medical profession, and it struck me on its perusal as demanding reply. I do not for one moment desire to advocate the repetition of changes in the regulations of the Apothecaries' Company, or the unnecessary length of time originally required for the actual servitude of an apprentice. The tedious routine of studies to which students are subjected also, I consider to be exceedingly unwise and harassing, and highly discreditable to the Court of Examiners, a fact which is rendered remarkably evident after reading the letter of "A Medical Pupil" in THE LANCET of December 12th. Nevertheless, whilst such a Company is upheld by Act of Parliament, it is necessary to comply with its regulations, though I trust that a day of change is not far distant. My intention now is to dissent from the opinion of your correspondent in imagining that a practitioner has any right to expect benefit from the assistance of an apprentice who has placed at the command of his instructor 200*l.*; and I contend that it would be contributing greatly to the good of all, if practitioners thought less of the services to be rendered by their apprentices, and attended more to furnishing them with the medical knowledge which young men are placed with them expressly to learn. The generality of apprentices are compelled to undergo, in the strictest sense of the term, actual servitude, during their whole apprenticeship, being constantly employed at the counter, dispensing medicines for patients, whose cases they never have an opportunity of investigating, and the effects of many of those medicines they never have time to study although to learn them they have already paid their premiums; and I cannot reconcile to my mind the propriety of exacting from them that "assistance" which should be obtained through the medium of qualified assistants. Having thus expressed my thoughts on a very important subject, I remain, Sir, your obedient servant,

A GENERAL PRACTITIONER.

December, 1835.

COMPULSORY APPRENTICE AND TICKET SYSTEM.

To the Editor.—Sir,—At a time so fraught with importance to the profession as the present, when a new, and, let us hope, an improved system, is to be introduced, it may be desirable to state even individual instances of grievances which have been inflicted under the old system. I mention one which is mine, and probably is that of many other students also. When I first entered the profession, being totally ignorant of its regulations, and thinking that a knowledge of medicine was the only real object to be sought, I was apprenticed to a practitioner residing a few miles from the metropolis, who, at the expiration of the first four years, I had the mortification to find, had not obtained the license of Apothecaries' Hall. I was then rearticled to a licentiate, but owing to this delay I had not commenced my hospital studies previous to the late regulations coming into effect, and (having but limited means) am materially checked in my advancement in the profession, the arrangements of the apprentice and certificate system have placed a veto of many years on my position as a candidate for professional honours and emoluments. I am, Sir, your obedient servant,

J. V. S.

HONESTY TO PURCHASERS OF FIRST EDITIONS.—*To the Editor.*—Sir,—When first I saw Dr. Mackenzie's work on the diseases of the eye I was induced to purchase it, and I look upon it as an excellent and elaborate treatise; but I see a second edition announced, with plates, &c. Now, Sir, those plates must be a valuable acquisition to the new volume. I trust, therefore, that in common honesty to the purchasers of the first edition, the plates will be enabled to be procured by them, in the form of an appendix. Waiting to know whether we shall have to thank Dr. Mackenzie for this measure of liberality, so rare amongst authors—certainly never observed by book-makers—I am, Sir, your obedient servant,

A POOR MEDICAL BOOKWORM.

Dorset, Dec. 1835.

MR. DEWHURST.—*To the Editor of THE LANCET.*—Sir,—I perceive another attack made upon me in your journal of this day, and shall feel obliged by your inserting this reply as early as convenient, particularly as it has been done by a malevolent individual to injure me. I never assumed the title of "Fellow of the Royal Society;" I know myself better than to assume honours never conferred on me. I never wrote a single article in the *Educational Magazine*, but in the *Education Journal* I added to my name

F.E.S.L., which was printed *F.R.S.*; this error was immediately corrected in the subsequent numbers by me; and I need not inform you that typographical errors frequently occur in the most eminent printing offices. I am not aware, Sir, that it is a crime to ask a noblemen or gentlemen to purchase my work, for the benefit of my infant family; although I am well acquainted with the individual who, under the assumed signature of M.R.C.S., has imposed upon you to insert the letter in question, as by an interview I could easily demonstrate. Had not misfortunes from a severe illness of two years from a dissection wound plunged me into difficulties, I should not have had to solicit subscribers. Had I been able to pay the fees, I long ago should most probably have been elected *F.R.S.*; and in consequence of my inability, Earl Stanhope three years ago generously presented me with a ticket, conferring on me all the privileges of a member of the Medico-Botanical Society; and similar honours have been conferred on me by many London, Dublin, and provincial learned societies. That I have founded a philosophical society I admit, and I can see no reason why my poverty should destroy my claims to the office of president, which I am proud to say I have held for two years with the approbation of the members (now about 320 in London and the country), and any time you choose to attend *yourself*, I shall be happy to transmit the necessary ticket of admission for that purpose. As to the latter part of the "M.R.C.S.'s" letter, I have already alluded to it in my letters inserted last summer in *THE LANCET*, so I shall not again refer to it. I remain, yours respectfully,

H. W. DEWHURST.

January 11, 1836.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Jan. 9, 1836.

Mr. RICHARD QUAIN in the Chair.

Dr. ADDISON, in the absence of more important medical news, related the case of a child, aged 11 years, in whose case he had committed an error of diagnosis (at Guy's?). The disease, as he had been informed by the surgeon who had sent the case, was one of amaurosis, dependent on a hydrocephalic affection. He was proceeding to prescribe accordingly, when one of his pupils put his ear to the chest, and detected mischief within. The chest was much contracted (the patient was "pigeon-breasted"), and the heart was heard beating violently. At the left side of the chest pneumonia was detected, accompanied by a mucous rattle, of a very peculiar kind, indicative of soften-

ing of tubercles, and he (Dr. A.) concluded, that the attack of pneumonia had accidentally supervened upon the tuberculated condition of the lung. The mucous rale was not heard at the apices, but as low down as the fifth or sixth rib, which added to the perplexity and interest of the case, and not feeling satisfied, he (Dr. A.) visited the boy at Hackney. By the treatment pursued, in spite, as he thought, of the disorganized condition of the lungs, the patient improved, but in an after examination he detected the source of fallacy. The boy was labouring under emphysema of the lungs, and when the pneumonia no longer existed the humidity disappeared, which had led him into error. He related the case, because we were bound in duty to narrate the truth in all instances. This would have been a very admirable case to have fallen into the hands of an empiric, who, if it had got well, would not have failed to blazon it abroad as the cure of a confirmed case of phthisis, so pronounced by the faculty. The case also showed the necessity of being exceedingly cautious in forming a diagnosis in diseases of the chest. The treatment consisted of moderate depletion, a mild course of mercury, paying attention to the bowels, and employing blisters, which occupied about a month. For the affection of the head he had been cupped. Mercury was still employed mildly, and the sight was fast improving.

Dr. LEONARD STEWART believed that if permanent benefit were derived in the short space of a month, whatever treatment was employed, we were justified in considering it not to be a case of phthisis.

Dr. ADDISON said that had the sound existed at the apex, instead of at the base of the lung, he would have pronounced it, without hesitation, the result of disorganization. Dr. A. then briefly detailed two other cases, occupants of the same bed, one the subject of pneumonia, and the other presenting pneumonia coupled with severe bronchitis, which bore on the question that was argued here some evenings back, when he (Dr. A.) maintained that in genuine pneumonia, little or no cough, and no expectoration, except it were blood, was present, and if a slight glairy mucus were secreted, it was from the minute extremities of the bronchial tubes, and it was from those symptoms being considered essential to pneumonia, that the disease was frequently passed by unobserved.

Dr. CROWE said that so long as no inflammation of the parenchyma of the lung, no expectoration was poured out, (as) when the disease extended to the bronchial tubes then there was expectoration. He (Dr. C.) did not consider this a new fact, but, on the contrary, a very ancient one.

Dr. ADDISON said that no correct information was to be found in any work on the subject, prior to the appearance of a man-

hec's; and Cullen, though the best of all authors prior to Laennec, his writings seemed a mass of confusion. But Laennec's enabled us to detect the disease of the chest with as much certainty as common experience, though we might meet occasionally with complications which were liable to puzzle us.

Mr. FERNANDEZ related a case wherein a physician, of no mean reputation, committed the following mistake. A stout man, of full habit, from early life had suffered from enlargement of the heart; for three months he was troubled with a constant cough, with slight expectoration. About a month back, as the respiration became very difficult and frequent, the physician was consulted and used the stethoscope, but he found some difficulty in explaining the nature of the malady. No respiration was to be heard over any point of the chest, nor any peculiar sound in the region of the heart; the expectoration was of a thick mucous character; the blood drawn was buffy. The diagnosis given by the physician was, that the patient suffered from acute bronchitis, and an effusion of fluid within the chest. Shortly after this examination a faintness came on, which was relieved by brandy, but at the expiration of a week a second returned and the man died. On inspection of the body after death, no fluid was found on either side of the chest, and the lungs looked perfectly natural, but on compressing them the contained air could not be forced out, the air-tubes being blocked up by the swelling of the lining membrane. The pericardium was highly florid and inflamed.

Some discussion ensued between Drs. Addison and Chowne, with regard to the writings of Cullen, the former deprecating them, from the confusion prevailing in the parts relating to the diseases of the chest; and the latter advocating them. The subject was then dropped to make room for that of magnetism, which occupied attention for an hour beyond the usual time of adjournment; but nothing was elicited worthy of being reported, and in order to produce from the diversity of opinions something more satisfactory, it was moved by Mr. CHINNOCK and carried, that Dr. Ritchie, who was present, be requested to enter fully upon the subject at the next meeting, when the meeting adjourned.

The President of the Royal College of Physicians had an interview with the Chancellor of the Exchequer yesterday, in Downing Street. A deputation of short-stage coach proprietors had an interview with the same right hon. gentleman immediately afterwards. — *Globe*, Jan. 12.

MEDICO-BOTANICAL SOCIETY.

OBSERVATIONS ON THE PERUVIAN BARK.

By GEORGE G. SIGMOND, M.D.

Read at the Meeting of the Medico-Botanical Society, Jan. 12, 1836.

It appears that at about the year 1639, the attention of the ecclesiastics in Spain was drawn to the bark of certain trees, which had about seven years before been imported into that country from Peru, their newly-acquired conquest in South America. It possessed a febrifuge power, which had been successfully exhibited upon a member of their own body residing at Alcalá. It had likewise acquired some degree of reputation amongst their own countrymen in the new world. The Jesuits, a powerful, active, and highly-intelligent order, who aimed to be the depositaries of the knowledge of the age in which they flourished, exerted all their influence over the Christian world, to diffuse, under difficulties of no ordinary kind, this important drug. Many failures, however, from an ignorance of the proper mode in which it was to be employed, and from the importation of varieties possessing little or no power, awoke feelings of the strongest prejudice against it. Several years elapsed, during which a severe war of words was waged, before it was universally acknowledged to be what Dr. Robertson, the historian of South America, has justly described it, "the most salutary, simple, and perhaps the most restorative virtue, that Providence, in compassion to human infirmities, has made known unto man." A beautiful tract, in our own language, from the classic pen of Sir George Baker, gives us a most interesting history of the first introduction of the Peruvian or Jesuit's bark into civilized Europe, and more especially into this country, and the numberless works that have been published on that subject are founded upon this essay. But many other points of very great importance have been discussed, and still remain for elucidation; for, although many inquiries have been instituted, and individuals of high scientific attainments have been engaged in various researches, who have, with diligence and discrimination, employed themselves in eliciting facts, we have yet much to learn, and much that is unknown, to discover. Ten years since, Heinrich von Bergen published a work in German, "An Attempt towards a Monograph of the Barks," in which he gave a list of no less than 632 authors who had written upon the subject, and of 808 books and pamphlets that had been published, and this did not contain some of the

most distinguished authors of Spain—viz. Masdevalla, Franzeri, Lopez, Banares, and since that time the discoveries which chemistry has made must have swollen the catalogue to an immense extent.

Of the subjects which have been treated, there are two questions which come more immediately within the scope of the inquiries of this institution, and which demand our attention. The first question to be discussed is, What are the trees which furnish the genuine cinchona, and how are they to be distinguished? The second is, In what way are the medicinal virtues which reside in these trees to be best obtained, for its administration in the great variety of diseases in which it has been successfully employed?

The first or botanical question, although it has been so much agitated, still remains in some degree of uncertainty; we appear now to be much nearer its solution than we yet have been. Amongst those from whose labours we have benefited, are some of the most distinguished men, De la Condamine, Joseph Jussieu, Mutis, De Candolle, Richard, Zea, Ruez, Lambert, Laubert, Humboldt, Bonpland, Viry, Fée, and "though last not least," Don. The second or the pharmaceutical question has also a long train of illustrious men to boast of. Pelletier, Caven-ton, Batka of Prague, Brera, Martius, Pfaff, Brandes, and I have on this occasion to point out the labours of our own chemist, Battley, which may be fairly considered as among the most important that have yet been undertaken.

It was in the year 1738 that the celebrated French mathematician De la Condamine, who was then resident in Peru, gave the first botanical description of the Peruvian Bark; but his wish to import it into Europe, either by seeds, or by cutting, was unsuccessful. The high estimation in which his efforts were held, is marked by the name which was by the universal consent of the botanists of Europe given to the tree which he described, and the *Cinchona Condaminea* was admitted in the Pharmacopœia. In Germany it was called "*Der Offizinelle Fiebertindenbaum*;" in France, *Le Quinquina*; in Italy, *China Chinachina*; in Spain, *Corteza de Loya*; in Portugal, *Quina*; in Holland, *Kinaboom*; in England, the *Peruvian Bark-tree*; in Denmark, the *Quinatree*; in Sweden, the *Quinatred*; and all the varieties of the bark found in commerce were implicitly believed to be the products of the tree thus described; different engravings of it have been given by Plenk, by Humboldt, and Bonpland; the one which is now before you, is from Nees Von Esenbach. Joseph Jussieu, who was in South America from the year 1739 until 1771, gave much attention to the barks, but seems not much to have increased our knowledge. In the year 1760, a year remarkable (as Doctor Manuel de

Gregorio, the biographer of Mutis, observes)* for the commencement of a botanic æra, Mutis disembarked at Cartagena, and commenced, amidst the woods and wilds of South America, a series of inquiries upon the vegetable system of the new world, which has bestowed upon the race of man, innumerable sources of comfort, and prospects of future benefits.

Although Fenelle, Plumier, and Loxley, had made some slight botanical researches, they had done nothing for the science, which they only occasionally cultivated; it remained for Jose Celestino Mutis to unfold the beautiful volume of the works of nature which lay before him, to select the richest page for his examination, and to give to mankind the valuable result of his studies. He may be said to have laid the foundation for a superstructure which has now arisen, and which remains to be improved by an ardent host of labourers anxious to follow footsteps, so clearly, so usefully, so justly defined. He quickly transmitted to Europe whatever information he could glean, collections, drawings, specimens, were forwarded by him to Linnæus, and to all the scientific institutions of Europe; and the epithets which were bestowed upon him, and the testimonies of approbation and of admiration which followed him to the grave, are proofs that his talents were appreciated, and that his claims were universally recognised. He first described the four species of bark, and gave a classification in concordance with the views of botany then entertained, and the boundaries of that science are now much enlarged, and therefore more accurate knowledge of the objects of nature has been attained. Still his name is venerated as the first correct observer and the best describer of what he saw. His pupil Zea followed in the path in which his preceptor had gone, and has also a claim to our respect and gratitude, as have also Ruez and Pavon, whose rich and valuable collection of dried specimens of the genus cinchona is now in the possession of that ardent and zealous lover of science Mr. Lambert, one of the vice-presidents of the Linnæan Society; to this collection has also been added that of Dr. Thomson, which was obtained by the capture of a Spanish privateer, which was carrying home specimens collected near Loxa and Santa Fe. Mr. Lambert published "*A Description of the Genus Cinchona*," together with a plate, which was of important service, as well from the original matter it contained, as from its giving us a translation of the papers of Humboldt. This interesting work,—accompanied by the collection which, through the liberality of Mr. Lambert, and his well-known love of science, is kindly open to the student of natural history,—may be said to have invited attention to a subject which had not in this country yet been at all handled. The travels

of Humboldt and Bonpland are next to be alluded to; their inquiries, and their descriptions of different species of this beautiful evergreen tree, have been taken by almost all botanists as the foundation of the different classifications which have been attempted since more regular and more natural arrangements have been followed, than the artificial ones which were so long admired.

The example of inquiry set by these botanists has been followed by other naturalists, but as the opportunities for conducting any inquiries are not very frequent, we must not expect that we are yet fully acquainted with the trees of the family cinchona, particularly as many trees possess in various degrees the power of depositing in their bark, secretions which possess the medicinal virtues which so remarkably reside in that which is called, as superior to all others, the bark. The modern genus cinchona is limited to about sixteen species; some which were formerly included are found very different in structure, and also in their properties. Amongst these are the different species of the exostema, the losmi-buena, &c.; these various families belong to a very extensive natural order, the rubraceæ, which possess families of great diversity of form and structure, as well as others which do not offer such striking marks by which they may be distinguished one from the other. In the last volume of the *Linnean Transactions*, is a paper, very short, but most valuable, which has thrown a new light upon the subject, and has furnished us with a key, whose application has unlocked an unexpected store, from which a guide through our difficulties is obtained. It is to Mr. Don we are indebted for a discovery of no small importance to us, and which adds a further claim to the consideration he already enjoys amongst naturalists. I am happy to learn that such a successor is appointed to our late lamented friend Gilbert Burnett, in the *King's College*: such a selection will be a source of gratification to every lover of that science which he has cultivated and adorned.

Mr. Don has taken the variations of the aestivation, or the manner in which the floral envelopes are arranged before they expand, as the character by which the different groups may be distinguished; and as these variations of aestivation are found connected with other differences in structure, it affords a very valuable distinction. He has observed, that in the true cinchonæ, of which he gives 37 species, the aestivation is valvate.

In commerce four important varieties of bark are found, which are again subdivided, as I shall hereafter have occasion to show you. 1. The Quina Naranjada, or orange-yellow bark, of which there seem to be two sorts; the calasaya, and the royal yellow quinquina; the first title, however, appears to be given by the native Peruvians to the superior bark, which they believe the yellow to be. 2. The quina rosa, or red bark. 3. The quina amarilla, or pale yellow bark, of which there are different sorts, named from the appearance of the epidermis. 4. The quina blanca, or white bark. The opinion has been adopted by various medical authorities, and the Pharmacopœias have also sanctioned it, that these different sorts of bark are the products of trees easily to be distinguished one from the other, and the Royal College of Physicians, taking Zea as their guide, have admitted three species—the cordifolia cortex, the lancifolia cortex, the oblongifolia cortex. Whilst Dr. Thomson in the London Pharmacopœia, following the authority of Mutis and Zea, considers the cortex cordifolia to be the pale bark, in Edinburgh College, "Dr. Dewart, and Dr. Powel, regard this as the species yielding yellow bark." Whilst the lancifolia cortex is considered by the former authorities to be the yellow bark, those whose opinion I have just alluded to regard it as that which furnishes the pale. The cinchona oblongifolia cortex, and the magnifolia, seem to be acknowledged as those from which the red is obtained. Drawings from these trees are placed before you. A list of the best engravings you will find in the work of Nees Von Esenbach. These discrepancies of opinion were unavoidable, from the limited knowledge we possessed of the trees; but we have now ascertained that the shape of the leaves cannot serve as guides to the peeler, and his practical experience must remain as his only assistant, until science has made some farther advance; at present he depends upon his eye, and upon the taste of the bark. Humboldt's opinion must be allowed to be quite decisive. He says, "I hardly know any one tree varying more in the shape of its leaves than cinchona. Whoever determines single specimens of

dried collections, and has no opportunity to examine or observe them, in their native forests, will be led to discover different species, by leaves which are of one and the same branch. The yellow bark we have found at one and at the same time with foliis ovato-oblongis, ovato-lanceolatis, and ovato-cordatis; Mutis calls it cordifolia, because it is the only kind on which cordate leaves are sometimes found. Even the laurel-leaved cinchona condaminea, the finest bark, from Uritusinga, has very diversified leaves, according to the altitude at which it grows, and which equals that of St. Gothard or Mount Aetna." Humboldt very properly points out the form of the flower as the diagnostic mark, but this of course is only useful at one particular season. Humboldt also took with printer's ink, impressions of the leaves, at Gonzanoma near Loxa, which still further corroborated his opinion that the distinction made from the shape of the leaves is unsafe.

I do not think that enough of facts have yet been accumulated, to enable us to judge of the value of the lichens, as a diagnostic mark of the species, but certainly their presence or absence may be considered as most useful indicators of the state of the bark. We know that the several species of the family rhizomorpha, are very active agents in decorticating dead trees; and, as has been observed, "they assist in the disintegration of lifeless organic bodies, which would otherwise encumber the surface of the earth, and be exceeding tedious in their removal."

Thus the rhizomorpha cinchonarum is a rare species, but whenever it exists upon the epidermis, it indicates that the bark is in a state of decay, and that it has lost its febrifuge power. Fee states, that the presence of himantia cinchonarum is a certain proof that putrefaction has very far advanced. The hypochneis rubro-cinctus and nigro-cinctus rarely grow in great quantities on healthy trees; and the opegrapha rizicola, and fissarina, likewise may be considered as indicators of the advanced age and impoverished state of the tree on which they are found.

When I have, at our next meeting, an opportunity of resuming this subject, I shall take up the pharmaceutical inquiries, more particularly those to which I have referred as entered upon by Mr. Battley, as he has, with great labour, gone through a series of most interesting experiments in his laboratory, which I shall have the honour of detailing to you.

That we cannot, then, look to the variation of the shape of the leaf, which must be affected by altitude, by age, by climate, by the situation of the tree, whether surrounded by others or standing alone, by many circumstances attending its development, I think must be admitted. Another source

of information has been sought, and some expectations raised, which I think cannot be borne out, namely, that by the lichens, or mosses, we can distinguish the tree. They have been studied with a praiseworthy ardour by botanists. Fee, more particularly, has devoted great attention to this subject; in his memoir on the cryptogamic epiphytes of the official bark, he has made some singular observations. He states that the gassicurtia is found, exclusively, on the yellow bark; that the graphis interrupta is found only on the bark of the lancifolia; these are the lichens which you find upon the specimens before you; and, after very careful examination of a vast variety of the different specimens of barks imported into this country, they are the only ones which I have been enabled clearly to distinguish. The ascidium cinchonarum, which is said to be found indiscriminately on them all, I have never observed, at least, taking the engraving given by our late professor, Gilbert Burnett, as my guide. Upon the red bark I have never observed the slightest appearance of adhering lichen; but this study is pursued under great disadvantages, from the want of a sufficient number of engravings to consult.

THE LANCET.

London, Saturday, January 16, 1836.

THE rejection, on Thursday sennight, at Apothecaries' Hall, of a student, who was a member of the Medical School in Aldersgate-street, has created a very strong sensation in several of the "recognised" establishments; because it was well known, not only to the lecturer, but also to the Aldersgate-street class generally, that he was fully capable of executing the duties of a medical practitioner in every department of his profession. The conduct of the examiner on the occasion in question was, we understand, that of a vulgar, rude, cruel, and unfeeling man, and the extent of his ignorance was fully proved by the error he committed in his insolent attempts to correct the individual who was subjected to his coarse and heartless scrutiny. As the examinations at our medical establishments are conducted in a manner, the pre-

cisely the same length of time will they continue to be made the instruments of oppression and injustice. The rejected candidate had been the apprentice of a gentleman who was not "in favour" at the Hall, and the cowardly expedient was resorted to of making an unoffending person suffer for the supposed misdeeds of another. On very many occasions similar brutality of conduct has been shown towards the students at the College of Surgeons; and the public may be assured, that whenever so much grossness of behaviour is manifested by men who are called upon to execute public duties, there must exist in those men a marked deficiency of the very qualifications which would best fit them for executing the duties of their office. The ignorant examiner, in fact, often subdues his victim by his insolence and his menacing bearing. Not five questions are asked before the student feels that he is to be disgraced. This distressing apprehension disturbs the operations of his memory, distracts his mind, and altogether renders the judgment incompetent for the performance of the task which he is required to undergo, and the unfeeling wretches who thus trifle with the feelings of the candidate, behold in the mischief they create the chief source of their own enjoyment, as they refer to the incompetency of the student, as furnishing the best proof of their own tact, skill, and dexterity, in conducting an examination. Most sincerely do we hope that another session of Parliament will not be allowed to transpire without bringing into existence a statute which shall have for its object the institution of a FACULTY OF MEDICINE in this metropolis, wherein all the examinations shall be conducted in public, upon the system of concours, or professional competition. The tyranny of "Rhubarb" rapidly approaches the hour of its termination.

The foregoing remarks were written by a gentleman, a copy of the following letter being sent from the gentleman whom

this foul attempt has been made to injure. The HALL of the HALL will, on reading it, be ready, we suspect, to plunge headlong into one of their own caldrons. The original of this letter has, we are informed, been transmitted to the examiners at the Hall.

"To the COURT OF EXAMINERS of Apothecaries' Hall, London."

"GENTLEMEN,—Having applied to you last night for the license of your Company, and having been examined by one of the members of the Court, and "rejected," I must attribute such "rejection" to the operation of some private feeling, which I have good grounds for supposing existed in the mind of my examiner. In order, therefore, to prove to THE PROFESSION, generally, and to THE PUBLIC, that such "rejection" was not the result of incompetency on my part, I demand from you a PUBLIC EXAMINATION, to be conducted in the presence of a professional audience, and I now state to you that I am ready to undergo such an ordeal on any day, and at any hour which you may be pleased to appoint.

"I am, gentlemen, your obedient servant,
"THOMAS SMITH.

"1, Jewin-crescent,
"Friday morning, 8th Jan. 1836."

MANY erroneous opinions are entertained relative to the power which can be conferred by the Crown on the governing body in granting a charter for the establishment of an University in this metropolis. Most of those opinions are equally absurd and unfounded, but there is one which operates at this moment to the disadvantage of professional and public interests. It is believed, we understand, that the new charter can bestow on the examiners of the University an authority, in awarding diplomas and licenses, equal to that which has been bestowed on the Court of Examiners of the Apothecaries' Company by the statute of 1815. In other words, it is believed that the University Charter

can empower the Senate to grant diplomas and licences which shall confer upon their possessors the privilege of engaging in medical practice in England and Wales. Hence a correspondent who signs his note "OBSERVER," "cannot conceive how the Editor of THE LANCET should be of opinion that, even supposing the University should be devoid of any great reputation, it should still offer no inducements to candidates to apply for the diplomas, when the possession of those diplomas will empower the graduates to practise in all branches of the profession, and would thus enable them to escape from the exertions practised in Lincoln's-Inn-Fields, and the degradation of resorting to the drug Hall in the City."

With regard to the College of Surgeons, it matters not what may be the arrangements in the new University. While we are without a FACULTY OF MEDICINE, and while the public in the distant parts of the kingdom are deceived by the name of "the College," there will be adventurers who will continue to give twenty-two pounds for a really worthless document, although it is well known to every professional man, that any individual may engage in the practice of surgery, without making any such purchase. Young men think it a fine thing to be enabled to show that they are Members of "the Royal College of Surgeons in London;" and as the generality of the community are ignorant of the character of the examination at that institution, the title often carries with it some importance in the minds of the uninformed public. If, therefore, the University be not founded on a principle of just and enlightened liberality, and if the examiners be not men of very distinguished and exalted attainments, and if they do not prove their qualifications by the mode in which they obtain their offices, the public will consider the title of "M.R.C.S.L." to be equally as valuable as that of "M.D.U.L." In short, it will be thought precisely as well of a man if he be a mem-

ber of a "Royal College of Surgeons," as if he be a graduate of a second or third-rate University. The new institution, therefore, cannot, in any manner, affect the legal privileges which the College of Surgeons can confer on its members, because, in point of fact, the College has none to confer. It can neither give to a man the right to practise surgery, nor take from any individual that right. It is, therefore, strictly speaking, an incorporated nonentity. The minds of the students, therefore, will not, in all probability, be influenced in the remotest degree, either in avoiding the College of Surgeons, or in applying to that institution for its diploma, by the institution of the new University.

In the case of the Apothecaries' Company, however, the bearings of this question are wholly different. In the instance of that establishment, if it be the object of the candidate to embark in the profession as a surgeon in general practice, he must obtain the license of the Apothecaries' Company, even if he should be a medical graduate of the Metropolitan University. It is on this account that our correspondent "OBSERVER," and many others, are deceived. The source of the error into which they have fallen may be found in the opinion they hold, that the powers which may be conferred by the new charter, can interfere with, or totally abrogate, the authorities which are now exercised by the Court of Examiners of the Apothecaries' Company. In order to dispel this erroneous view, it should be recollected that no charter can destroy, or even weaken, the powers which are exercised under an Act of Parliament. Unless, therefore, the Apothecaries Act of 1815 be repealed, the new charter could not operate to the prejudice of the drug-dealers in Blackfriars, and if this Act were abrogated, it is to be hoped that there could then be no interest connected with medical practice left to be prejudiced. But a charter, it should be distinctly understood, cannot annul the provisions of an Act of Parliament. In fact,

the principles and details of every charter, must be in accordance with the statute and common law of the land. If it be constructed otherwise, that is, if it be framed in opposition to the law, it becomes at once an *illegal instrument*, and, accordingly, entirely *inoperative*.

It is impossible therefore to commit a greater blunder than to believe that the new charter can break down the monopoly, or soften the tyranny, of the Apothecaries' Company, or in any respect control the proceedings of the London College of Physicians, because the functions which are exercised by the drug corporation were created by Act of Parliament, and the privileges of the College of Physicians arising out of the charter granted by HENRY the EIGHTH, have been confirmed by Acts of Parliament. The new charter will necessarily be directly powerless with reference to both of these corporations, and, as we before stated, if it is to become, in law, a valid instrument, it must be so shaped as to operate in conformity with the existing statutes and prescriptive customs of the realm. In granting a charter, observe, it is presumed, both by the spirit and the letter of our constitution, that a sacrifice is made of a portion of the royal prerogative, in order to advance the public interests. The power, therefore, of granting a charter, is, in itself, a lawful condition, or prerogative, sanctioned by our free constitution. Accordingly, that power, it is easy to conceive, must, in all cases, be exercised in accordance with the authority of existing statutes; for if it could be adversely used, with reference to the law itself, the royal hand might, for very unworthy purposes, push aside by degrees all our ponderous volumes of statutes, and the will of the King would in such case establish a tyrannical supremacy over the legislative rights of both Houses of the senate.

Being, therefore, that the new charter, in order to become law, must be moulded into a form which is suited to the spirit of the law, and analogous to the circumstances

which the law itself has created, we are anxious to learn,—as the new instrument cannot subvert existing rights,—how far any new rights and privileges are to be established by it, in accordance with, or adverse to, the rapidly advancing knowledge of the times in which we live. We have called, repeatedly, for THE EXPOSURE OF A DRAUGHT OF THE INTENDED INSTRUMENT, and we must confess that we have formed a wrong estimate of the minds of his Majesty's present Ministers, if they cause this document to be projected and executed in secret. If the thing is to become law, the public ought to be made aware what are proposed to be made its conditions, but if it be not to possess the weight of a legal instrument, but is created for the sole purpose of calling into birth a series of empty and worthless titles, it must be regarded as an act of solemn mockery, which deserves exposure and general condemnation.

It has been remarked that there is no precedent for the publication of the intended charter,—say, in the Government Gazette. The proof of this omission of publication is not, alas! wanting in words. The effects have long been sufficiently perceptible in the proceedings of the College of Surgeons, the College of Physicians, and other chartered bodies. If there be no precedent, so much the worse for the public; for so many the more injurious charters have crept into existence, and, as the only effectual corrective of the evil, let the precedent be immediately established. The circumstances which transpired in the years 1799 and 1800, are admirably illustrative of the advantage of publicity, and the evils of secrecy, in matters connected with legislation. The managers of the old Surgeons' Hall applied to Parliament for an Act of re-incorporation. Their bill was introduced, and, on its infamous provisions being made known, the profession denounced it as with one voice. A stormy discussion afterwards arose in the House of Lords relative to its proposed enactments. An admirable speech was made

upon it by Lord THURLOW. The principles of the measure were denounced as being narrow-minded and iniquitous in the extreme, and the advocates of the scheme were abashed and dismayed, and shrunk from the dirty labour which they had been called upon to execute. The bill, therefore, was kicked out of Parliament; but it met with that fate because, and only because, its odious provisions had been subjected to the scrutinizing examination of the members of the profession.

Now mark. In the following year, to what manoeuvre did the old corporators resort? Why they went *stily* and *secretly* to the King, and petitioned His Majesty for a charter of incorporation. The scheme was successful. The royal ear was abused, the members of the Privy Council were either knavish, asleep, or deluded, and the instrument was fabricated. The results have been known and felt by the surgical profession in England, during the last six-and-thirty years. The charter thus cunningly obtained, was fabricated out of the identical clauses which were contained in the Bill that had been so scornfully, so indignantly rejected by the House of Lords in the preceding year.

This is a most instructive historical lesson. Are we to be insensible to the admonitory indications of experience, and remain unmoved by the evidence of facts, the force of which any child may feel and understand? We most emphatically exhort the present liberal Ministers of the Crown, not to tarnish their reputation, or derogate from the character which they have established for open and straight-forward dealing with the public, by obtaining for the intended charter the sign-manual of the KING, until the country is placed in full possession of a knowledge of its intended clauses. Assuredly it must be confessed that a *system of courtly intrigue and secrecy*, in framing laws which are designed to affect the most important interests of the community, is utterly incompatible with the spirit and operations

of a representative government. In the last session of Parliament the charters of our municipal corporations were all demolished, as the enormities to which they had given birth could no longer be endured. Those instruments of oppression had all been obtained in secret, but the acts of injustice which have been perpetrated under them, operated on the *public*. Could those charters have been obtained, except by some secret, some covert method? If the application for each municipal charter had been made a subject of discussion in Parliament, it is utterly impossible that the principle of self-election could have sustained its ascendancy during so many lustres as it has done centuries. *Secrecy* was the source of evil on every occasion when a municipal charter was granted, and in founding an university in the metropolis of this empire, no man in his senses can believe that a liberal Ministry will plunge headlong into such a poisoned source of irremediable of mischief.

NEW METROPOLITAN UNIVERSITY.

(From an Edinburgh Correspondent.)

THERE has not been a topic of more general conversation for a length of time amongst us here than the Metropolitan University, all classes of society being interested in the well-being of our own college; for the average number of students usually amounts annually to as many as two thousand, producing, as you may suppose, a very considerable revenue, not only to the cormorants of the University, but also to the tradespeople of the town. Though some of the other lecturers in the University may suffer more or less, yet it is the members of the medical *sensatus* who are most alarmed on the present occasion, and certainly not without good cause. They have enjoyed, it may be truly said, a complete monopoly in the manufacture and sale of degrees for at least a century past; and one year after another have the medical professors used all their ingenuity to increase the price of a *degree*, until, like all Jews in trade, it has been mounted up so high that others have been induced to bring the same commodity to market at a lower rate of charge. It is not much more than twenty years ago that they added twenty-five per cent. to the price of each ticket, but Dr. JOHN THOMPSON'S

liberal additions to the curriculum gave them a death-blow, which they are all aware they never have recovered, nor ever can. It is only to be wondered at that their monopoly has lasted so long, and that the largest and greatest metropolis in Europe has not until now competed with them, and had a University within its own precincts, without compelling its inhabitants, as well as those of all England, to repair to Scotland, not in search of knowledge, but in order to be *dubbed*. I consider this fact, indeed, to be a monstrous anomaly in the history of civilized nations. Notwithstanding the absurdity of the attempt, our Edinburgh medical professors are determined to make a struggle to arrest the progress of reform in medical education. Meeting after meeting has taken place among them, and if I mistake not you will soon see one of our anti-liberals amongst you, to sow the seeds of discontent, and nurse the tree of corruption. Young THOMSON is too well known from his *past* services, so that a *new* man will be sent to London.

Sir CHARLES BELL is not yet come, and Dr. JOHN THOMPSON, who knows him of old, quaintly observed the other day, "That if the surgical knight does not come down immediately, he never will come at all." My own opinion is that he may yet give us he go-by, for it is not common, nay I doubt if it ever occurred, that a Scotch doctor who had once crossed the Tweed ever returned to his native mountains. Parritch and kail are poor fare after roast beef and plum-cudding. However, times are changed, and Sir CHARLES's discomfiture at the *London University College*, the total failure of the *Middlesex school*, and the approaching revolution in Lincoln's-Inn-fields, may induce the chivalrous knight again to try his fortune here.

As it is most likely that you have not already seen it, the inclosed copy of his letter, *accepting* the chair, will amuse you. It is an excellent portraiture of the man, whose vanity is so prodigious, that he never loses an opportunity of talking about "I, myself;!"

* "Brook-street, 11th Dec.

"MY LORD,—I have had the gratification of receiving your lordship's letter, and accept the honour which you, the magistrates, and council, have conferred upon me. The manner in which this appointment has been conferred, and the assurances with which your lordship has accompanied the communication, lead me to anticipate the harmony in our endeavour to cultivate medical science, and promote the reformation of the University. You place me where there is every motive for personal exertion; but where, most of all, experience and judgment are necessary. As to the first, I trust my habits of life give you sufficient warrant. For the rest, I ground my

The anatomical teachers, as well as the students, have become exceedingly impatient, because the "inquiry" which was instituted to inquire into the conduct of Dr. CRAIGIE, our anatomical inspector, has not yet been brought to a conclusion. This circumstance has heaped such odium on the public functionaries, whose duty it was to have prosecuted the investigation without delay, that a public meeting of the students is contemplated, as the coarse and insolent doings of the awl-wise "man of leather," as CRAIGIE is called, has caused an universal feeling of disgust in the schools, and has materially interrupted the teaching of practical anatomy here.

Another topic has formed the subject of a good deal of conversation here, though it may be of too trifling a character to interest you. Dr. ABERCROMBIE has received a medical degree from Oxford! This appears to us to be strange, as we have always flattered ourselves that one from our own University was the *best* of any, whilst we have always ridiculed degrees from an University where medicine is *not taught*. Although to us the matter is inexplicable, you perhaps may see further through it. All we know is, that Abercrombie, though a very pious man, is a cunning, intriguing little fellow, and when he went up to London to be examined before the Parliamentary Committee, he made himself Sir HENRY HALFORD's most obedient humble servant, and toadied him in all ways, which makes us

hope of being useful, on the characters of those distinguished men, many of them removed from the stage, with whom I have been united, or with whom I have been in consultation on many trying occasions. By this intercourse my opinions have been matured, and now, through your kindness, I shall use the advantages which time and circumstances have given me, so as to preserve the record of the opinions and practices of the men who have raised the profession of surgery in these kingdoms to its present acknowledged perfection. By this, to me, eventful change, I am led to reflect on the advantages I have possessed, in my anxiety that your lordship and the council shall not have occasion to regret the decision to which you have come. The unanimity of the council, and the very flattering expressions of your lordship, lessen the regret which every one must acknowledge to be natural to me in leaving a society where I have experienced uniform kindness and liberality, and in breaking the intimate and friendly relations with some of the most estimable men of our day.—I have the honour to be, my Lord, with great respect, your lordship's obliged and very humble servant,

"CHARLES BELL.

"To the Lord Provost, &c."

believe that your wily President must have been the means of sending him the Oxford degree, in payment for the humility and meekness shown by him, and for certain "services" hitherto unknown.

ST. GEORGE'S HOSPITAL.

ELECTION OF A CHAPLAIN.

A VACANCY having occurred in the office of chaplain to St. George's Hospital, in consequence of the resignation of Mr. Walker, the candidates for the appointment were, the Rev. FRANCIS GREGORY LE-MANN, and the Rev. Mr. NEVIN. The election, which was actively contested, terminated on the 8th instant in favour of the latter candidate—the numbers at the close of the poll being as follows—

For the Rev. Mr. NEVIN 156

For the Rev. Mr. LE-MANN ... 81

Without attempting to institute any inquiry into the merits and qualifications of the candidates, it may be remarked, *en passant*, that the regret felt within the hospital, amongst those who are most properly interested in the result of the election—the sick inmates—may be expected to be very great, at the non-election of Mr. LE-MANN, who by his kindness and attention to the sick, during the seven or eight weeks when he officiated in the hospital for the Rev. Mr. WALKER, previous to his resignation, succeeded in obtaining the approbation and good will of every inmate of the institution. Mr. LE-MANN is well known, by those who have the gratification of his acquaintance, to be possessed of liberal and enlightened sentiments, and an excellent knowledge of classical literature, having, at a very early period of his career, obtained a fellowship in King's College, Cambridge. Testimonials of a very flattering kind relative to the faithful and zealous discharge of his ministerial duties were produced in favour of Mr. LE-MANN, from clergymen of high character, by whom he had been employed as a curate; and had not the election been interfered with by the medical and surgical staff of the hospital (with the exception of Dr. WILSON and Mr. WALKER), there is every reason to suppose that Mr. LE-MANN would have been elected by a triumphant majority of the independent governors, many of whom are much disgusted with the indecent interference of the medical oligarchy, who for years past have trafficked in all the hospital appointments. It was frequently remarked, in the course of the canvass, by the independent governors, that the officious conduct of the Brodhan party in all matters relative to the hospital had prevented them from attending the board-room, as well as from voting at elec-

tions, and that they were fully determined to abate the nuisance by withdrawing their support and influence as soon as the term of their annual subscriptions should have expired. We were informed, and believe it to be correct, that Mr. NEVIN has not had the benefit of a collegiate education. The conduct of one of the medical officers, whose name is unworthy of mention, has met with the severest reprobation. At the commencement of the canvass, he announced that he was favourable to the election of Mr. LE-MANN, and actually tendered to one of his friends, instructions relative to the most appropriate course to be pursued in order to obtain the chaplainship, although at the very time, the hypocrite was actively canvassing for the other candidate. Personal exposure and rebuke, however, have followed this deception, which the party is not likely to forget during the remaining days of his earthly pilgrimage.

The British and Foreign Medical Review.

Edited by JOHN FORBES, M.D., F.R.S., and JOHN CONOLLY, M.D. No. 1. London. Jan. 1836. Sherwood.

A NEW candidate for the favours of the medical profession has wedged itself in amongst the periodicals, between the *Medico-Chirurgical Review*, and the *Edinburgh Medical Journal*. Which of the three at last will go to the wall we pretty well know, but object to alarm either party by publicly stating. We are well enough pleased to see the work, as strenuous friends of competition in all the departments of medical sciences. Who, indeed, have more reason to be pleased with rivalry amongst periodicals? We have witnessed the life and death of twenty claimants of that class since the year of our Lord 1823, each new "journal," *mock Lancets* and all, by thrusting itself beneath the pedestal of THE LANCET, serving as an additional lever of elevation to this work.

The Editors of the *British and Foreign Medical Review* came forward professedly as chiefly, we believe, with these two excuses for their project; first, that foreign medical literature had not obtained the attention which it deserved from the existing medical periodicals of these countries; and, secondly, that the criticisms and analyses of English works, which appeared in our quarterly medical journals, were not "free and candid" productions, not furnished by "wise

'era possessing a competent knowledge of the previous literature of each article, or as the work reviewed might demand,"—were not "the productions of men of experience and efficient acquirements, independent of the influence too evident in the hasty productions of juveniles and inconsiderate writers,"—that the task had been "hitherto confided to persons little qualified to undertake it," to "inexperienced reviewers, however able (!)," "to misrepresenters and critics of limited knowledge," "uncandid persons," and youths of "unexercised judgment."

This was a tolerably smart slap in the face for Messrs. JOHNSON, (senior and junior, according to the title of the *Medico-Chirurgical*), with how much justice or decency inflicted, we profess not to say. Such, at least, they felt it to be, whereupon an attempt was made to laugh down the new editors, as they were seen rising through the trap-door, with the announcement in their mouths that they appeared as "writers of known and unquestionable respectability." We are obliged to presume that this character was assumed by the Editors in their own persons, because those gentlemen are the only "writers" who are stated, and are, therefore, acknowledged and known, to be contributors to the first number of the new journal. Or was this an oversight, and contrary to a possible expectation, after such a declaration, that the name of each critic or analyst would be attached to his respective article?

In considering the question of "success" in the establishment of a new periodical, the point of debate with the projectors is—or ought to be—generally, that of the *means* of the class of persons to whose interests it is to be devoted, or whose attention it is designed to arouse. To talk of there being "room" or "no room" for a new work is absurd. There is always abundance of room where the arena of literature is not crowded with obstacles to publication erected by the law,—where there is perfect liberty of the press. But though there be whole acres of "room" for the million of mares, there may be more market than buyers; the buyers may be few, or not in want, or already supplied, or lacking in riches, and we certainly suspect that one or other of these conditions will prevent the career of three quarterly medi-

cal journals in this country from being very protracted. Why, Mr. Souter's quarterly journal is but just dead! The Edinburgh has long ceased to circulate any where but amongst a *very* select few at home, and some hundred or two surgeons on naval stations abroad; Dr. JOHNSON once had such a struggle for it, that nothing but the excitement of change, backwards and forwards, from quarterly to monthly, and monthly to weekly, and weekly to quarterly issues of his work, kept it in life and being; and last, though not least, one of the editors of the new journal has already experienced a signal failure as editor of a medical periodical. As, however, there may be purchasers enough to sustain one quarterly journal, it must be a strife of industry, we suppose, amongst the Editors, whose shall be the better production, the last speculation, however, always working under the disadvantage of infancy. Of "industry," we say, because the labourers in the field of literature are open to the engagement of all, and that *redacteur* would be unwise, indeed, who would work with the aid of inferior talent, when better was to be obtained.

By-the-bye, there is one division of the field in which no quarterly journal has yet gained a character, or even sought it,—that of medical politics,—taking arms in favour of free and liberal medical institutions. Not that anyone of them has eschewed the question; but each has either at once declared an open enmity to thorough medical reform, or has sneered at its noble and generous views, or has with one hand tried to retard its progress, while aiding it with the other. Thus have we seen the most diverse and opposite views in one number of the quarterlies, on the subject of medical government,—good principles, and wretched and impossible details; or correct details with expressions of horror at sound principles. There never seems, indeed, placed over them that watchful eye, and that revising hand, which are essential to ensure high and sterling character,—and inspire confidence in the sentiments and opinions expressed in the name of "We," and the reader never appears to detect the real views of the presiding genius, excepting when the declarations are *adverse* to the cause of medical reform.

It would puzzle us, for instance—perhaps

not worthily—to divine the principles that could be defended on the views which prevail in the new journal. Thus, at page 2, we find a most unhappy sigh over “medical instruction,” doubtless in consequence of some obscure impression on the part of the writer, that “Government” is about to adopt a change in medical law which will tend to increase the amount of learning and scientific acquirements in the medical profession of England,—that is to say, literally, to upset the ticket and certificate system in medical education. Yet at page 6 is to be found the following unconsciously uttered anathema against that very system, which for us to explain and apply is superfluous:

“The number of young men sent to their studies in London is, we apprehend, considerable; and we can never look upon the outflow, ardent and hopeful countenances of the junior students, at the commencement of each session, without our thoughts being carried to their several homes, where efforts are making, and sacrifices, of which young students are not always mindful, and which give something of solemnity to the acrid engagements so boldly entered upon by their public teachers, in years which are to determine whether or not those sacrifices are to be made, and not a few parental anxieties to be endured in vain.”

“Sacrifices,” indeed! Sacrifices to the god MAMMON, in the temples of the “recognised” hospitals and schools, the College and Halls, where, for simple bits of worthless paper, thousands upon thousands of pounds are annually extorted from the “anxious parents” of the certificate-lacking students. The abolition of this system, on the one hand, and its sacred preservation on the other, are the ultimate points for which medical reformers and the monopolists ever struggle.

Of the execution of the new Review, we are yet hardly prepared fully to speak. The first article, however, is injudicious enough to surprise us. Is it for the production of this kind of analytic and critical articles on foreign works,—articles not of the slightest value at home—that the projectors considered a new medical journal necessary in London?

On the whole, there seems to have been a want of industry in the conductors of the first number.

Case of Loss of the Uterus and its Appendages, soon after Delivery, with Remarks on the propriety of removing that Organ, in Cases of Interion or Scirrhus. By JOHN CHARLES COOKE, M.R.C.S.E., &c. E. Cox, Southwark, 1836. pp. 22.

FROM a little pamphlet which has just been transmitted to us under the above title, we condense the following curious statement:—

CASE.—At four o'clock a.m., May 22, 1835, Mrs. Aston, midwife, of Coventry, was requested to attend a woman in labour, who she found had already been in labour forty-eight hours, upon her knees, insisting upon being delivered in that position according to the custom of her country, Ireland. When induced to lie on the bed, an examination of the parts showed the os tincæ dilated to about the size of half-a-crown; the child's head presenting as usual. Every thing went on well, and the woman was delivered at 7 o'clock, the same evening, of a living child. The placenta followed whole in a quarter of an hour, being expelled by a pain. No hemorrhage ensued at the time, although a considerable quantity of blood was lost during the night. The after pains were trifling, and she felt so well, that she partook plentifully of animal food immediately after the midwife left.

At about four o'clock on Sunday morning, May 24th, Mrs. A. was hastily summoned in consequence, as the messenger stated, of the appearance of another child. The woman had risen during the night, and had gone into an adjoining room to make water; when her screams alarmed her husband, who called in some of the neighbours, and found the woman seated on a stool before the fire, with a vessel of warm water in front of her, and a large substance, which they compared to a child's head and neck, lying between her thighs, supported by her hands. The hemorrhage had been profuse. The midwife found the woman on the bed, pale from loss of blood, and in considerable pain. The blood had even run on to the floor. The uterus was lying on the bed, loosely connected to the vagina by a shred of membrane only. It was removed without effort, and placed in a bowl. The hemorrhage then ceased, and next morning the midwife brought the substance to my father, who discovered, to his astonishment, that it was an uterus inverted. At 10 o'clock he visited the woman. She was completely exhausted, extremely pale, throwing her arms about: pain was not perceptible. She had passed some blood shortly after loss of the uterus, as she said the following morning. Her bowels had not been relieved for nine days before delivery, except a mass of hardened fecal matter which was discharged with the last pain in the labour.

The woman did not much complain of any sensation like bearing down, nor of any substance lying in the vagina, nor of suffering much pain: neither was there much distention of the abdomen, nor was there then or at any time during the progress of the case, any thing more than a slight degree of tenderness, which, however, was hardly noticed, except upon pressure. It was apparent on the left lumbar region only. The only part of the uterus and its appendages not found in the bowl, was the left ovary. The uterus, on inspection, was a heavy, hollow, but firm pyriform body, very nearly as large as an ordinary child's head, at term. No laceration was visible, except a slight rent in the posterior lip of the os uteri. The attachment of the placenta was distinctly marked, being of a deeper brown red than the remainder of the mass; a quantity of flocculent matter adhered at its site to the walls of the uterine cavity. It was inserted over, and concealed the opening of, the left fallopian tube. This orifice was easily discovered by detaching a small portion of the loose flocculent substance. The vessels were large and tortuous, and fully accounted for the great hemorrhage. Upon making a section along its anterior aspect, the broad ligaments, with both fallopian tubes, and the right ovary, were discovered. The fibrinated extremities of the tubes were particularly clear and distinct, the left ovary appeared to have been detached, and to have remained in situ.

My father judged it prudent not to institute any examination per vaginam, fearing, also, that any salutary union of the sides of the vagina might thus be retarded, and risk an ulterior prolapsus of the abdominal viscera. He enjoined perfect quietude and absolute restriction to the horizontal position, abstaining from active medicine, and ordering a light farinaceous diet.

May 25. Monday morning. The patient had risen during the night, and passed her urine freely. She had slept, and appeared as well as on the previous evening. Towards evening she passed several small micturæ. She went on without accidents, except some increase of tenderness of the side, and some degree of fever, and diarrhœa on the 27th of May, which continued for three or four days, but which was then checked, and from that time she gradually regained her health and strength.

Previous to her confinement, milk was secreted in considerable quantity, but immediately after the loss of the uterus, this secretion, together with that of the lochia, was arrested, yet she persisted in applying the child to the breast, which induced considerable pain and hardness of the right mamma, attended with much febrile excitement. These symptoms subsided upon the exciting cause being removed. When

her health had been in some degree re-established, she again gave the child the breast, and persevered in doing so during several weeks, until, finding that she had no milk, she finally desisted. During the febrile attack, the tongue at no time exhibited any approach to a furred state. She is now in tolerable health; her complexion is pale and sallow as before, and she complains of a good deal of debility, but not such as to preclude her from following her usual occupation.

The child was for a long time in good health, but about a month since it was attacked by diarrhœa and died.

Principal Physiological Phenomena.—Those which present themselves in the history of this case are, the sudden and immediate suppression of the secretion of milk, and the absence of any flow of the lochia. So trifling indeed was the quantity of the latter, that the napkins were but slightly soiled; the hemorrhage too was completely arrested, as she did not lose a drop of blood after the morning of the 24th (Sunday). There is this additional peculiarity connected with the former fact—viz. that the milk had already appeared in considerable quantity before the loss of the uterus, but was entirely and permanently suppressed within two days after the separation of that organ. It was with a view of restoring the supply of this fluid that the woman persisted in applying the child to the breast, and, impressed with the same idea, she continued to do so until within a short period of the child's death, when finding her efforts vain, and that not a drop ever exuded, she finally desisted. She was repeatedly remonstrated with upon the subject.

The absence of all peritoneal inflammation, also, is a circumstance particularly worthy of remark, no means being taken to prevent it. The only symptom which ever caused any anxiety as to peritonitis was a slight degree of pain in the left lumbar region. The great quantity of blood lost when the uterus was separated, might in some measure serve to explain this singular fact? With regard to the violence which effected so complete a removal of the uterus, thirty-six hours after delivery, it is almost impossible to conceive it to have been offered by the woman herself, and yet such, there is every reason to believe, was the fact, if violence alone can suffice to account for such an event. The midwife most positively asserts, and her statement is strongly corroborated by the neighbour who first saw the woman on the morning of Sunday, that no effort was required to remove it from its loose connection with the vagina.

It is equally difficult to account for the inversion of the uterus, or to state when it occurred, as, from the appearance presented on examination, it must have been

pened spontaneously, no traces of any violence existing, and no portion of the placenta or other body remaining, by which sufficient traction could have been made. Previous to its descent on Sunday, nothing, which could have led to any suspicion of such an event, had happened.

The fact of none of the viscera following the uterus, and the total absence of bearing down, are equally inexplicable, unless we adopt the idea that the rectum, distended with fecal matter, had fallen forward towards the pubes, and closed the sides of the vagina. Yet the woman had not the slightest difficulty in micturition. I have not been able to ascertain whether she passed urine on the night of Friday. This circumstance will, perhaps, bring us nearer the epoch of the inversion of the uterus, as it is difficult to suppose a body of such magnitude to have been in the vagina without obstructing the flow of urine. Owing to her constant refusal to permit any examination per vaginam after recovery, I am not able to describe the parts at the present moment. Probably the vagina forms a cul-de-sac, in consequence of the adhesion of its opposing surfaces. Sexual intercourse has repeatedly been had with her husband, no mechanical obstruction existing.

In connection with the loss of one ovary, it is interesting to be able to state, that, although no impediment to coitus exists, yet the usual feelings and desires are entirely wanting. This might have been anticipated had both ovaria been removed, but one still remains *in situ*. Of course the menstrual discharge has never reappeared; even the small quantity occasionally furnished by the vagina has not been observed.

The history of this case demonstrates the possibility of removing an organ so voluminous and essential as the uterus, together with the ovaries, fallopian tubes, and ligaments, with only a slight impairment of the general health.

A question has been raised—Can a woman, after extirpation of the uterus, ever become the subject of an extra-uterine conception, should the vagina not close and form a cul-de-sac? It is obvious that nothing of the kind can ever happen to the woman whose case forms the subject of these pages, as the left ovary was the only portion of the uterine appendages not found in the bowl, and all sexual feeling is extinct.

I have not met with any case which may fairly be considered as parallel to the present. In all the other cases the mamma became wasted and absorbed: in the present instance they are still prominent, but this, I think, may be attributed to her perseverance in permitting the child to suck.

MODE OF

REPRODUCTION OF BONE AFTER
EXPOLIATION.

In the *Edinburgh Medical and Surgical Journal* for January 1836, we find an article of which the following is a condensation. It occurs under the head of "*Clinical Report for the Summer Session, 1835*. By Mr. JAMES SYME, Surgeon to the Royal Infirmary:—

There are still several circumstances in the history of necrosis which remain very mysterious. One of the most interesting of these, is the process by which exfoliations comprehending the whole thickness of a bone are reproduced. Sometimes nearly the entire shafts of the tibia and humerus come away. But we have seldom an opportunity of investigating by dissection the reproductive process at a stage sufficiently early for discovering the nature of the steps by which it accomplishes ossification. In the case which is now to be detailed, the process of reproduction had advanced just to the extent desirable for pathological inquiry, and I think it will go far to put at rest the long agitated questions on this subject:—

Case.—Beatrice Stokes, aged 13, strained her ankle by a false step on the 24th of March. Rigors, vomiting, and headache, attended with intense pain in the leg, and the usual symptoms of inflammatory fever, soon followed. She was sent to the *Royal Infirmary* on the 21st of April. From the middle of the thigh down to the toes, the limb was red, swelled, and tense, except at the fore part of the leg, a little above the ankle, where fluctuation could be felt. Incisions were made, a large quantity of thick dark-coloured matter was evacuated, and the patient greatly relieved. Through the openings the bone was found extensively denuded, and it became necessary to amputate the limb. The recovery was tedious, but perfect.

Examination.—When the limb was examined, it appeared that nearly the whole articulating cartilage of the ankle-joint had been removed by ulceration, leaving the bone bare and rough. The shaft of the tibia seemed to be dead throughout almost its whole extent, and had already undergone considerable erosion by the absorbents at its junction with the cancellated cartilage adjoining the epiphyses. When the finger was carried along the surface of the dead bone through an incision that had been made to expose it, a dense case or shell was felt, which, when displayed by dissection, proved to be the periosteum greatly thick-

ened, with osseous matter deposited in its substance. The membrane was traced distinctly from its sound part, where covering the epiphyses, over the dead shaft, and no one who saw it could doubt that it afforded the bed or matrix in which the new bone was deposited. Where covering the posterior surface of the tibia, though detached from the bone, it had suffered comparatively little change, which rendered its recognition at other parts more certain. The new bone did not constitute a continuous shell, but was deposited in flat masses, or scales, of various extent, between which the periosteum intervened so as to insulate them completely from each other, or any portion of the old bone retaining its vitality. The osseous substance lay on the inner surface of the periosteum, with merely a fine film of the membrane covering it, but with a considerable quantity of soft gelatinous substance like coagulable lymph effused over this, so as to line the interior of the case. At several parts of irregular size and figure, the periosteum did not exist, and at these parts there was a corresponding deficiency in the new bone. These apertures resembled the *cloaca*, as they are named, which exist in the investing shells that are formed in cases of necrosis, and are usually ascribed to absorption induced by the pressure of matter confined within the bone. But it seems more probable, from this case, that the deficiencies in question depend upon the periosteum being destroyed at particular points in the commencement of the disease.

Remarks.—In explaining the history of this case, I think it may be reasonably supposed that the strain of the ankle occasioned inflammation of the joint, which extended to the tibia, and led to ulceration of the articular cartilages, and death of the shaft of the bone; that then suppuration took place under the periosteum, which having become at some parts disorganized, allowed the matter to pass outwards and distend the skin; that lymph was effused from the inner surface of the remaining periosteum, and also in its substance, so as to render it much thicker and softer than usual; and that then bone was deposited towards the inner surface of the membrane in numerous detached points, from which it was proceeding so as to make them coalesce, and constitute a cylindrical case to the shaft.

KING'S COLLEGE, STRAND.

To the Editor.—Sir, Devoted as you have ever been to the interests of the medical student, I presume now to address you in hopes that you may be able to suggest some remedy by which I can be compensated for the loss of time and money which I have sustained

from having entered as a pupil this session at *King's College*.

It appears to me, as the professors have not fulfilled their agreement, that a part, if not the whole, of the money I was obliged to disburse, on entering, should be returned to me. Dr. Bisset Hawkins, as you well know, has not given a single lecture this session, and in his stead we had nothing but a hum-drum Scotch parson, who preached most soporific twaddle to us. Professors Hawkins and Mayo are in constant strife, and as their resignation is considered certain, their lectures are proportionably slovenly and incomplete. Your candid opinion and sincere advice will oblige your sincere admirer,

A KING'S COLLEGE STUDENT.

Strand, Jan. 6th, 1836.

. If the writer thinks he could establish a charge of obtaining money under false pretences, he might succeed at one of the police offices. It is in the Bow-Street district.

Mr. DON has been elected to fill the vacant chair of botany at the *King's College, Strand*. Between that school and the *Charing-Cross Hospital*, nothing decisive has as yet been arranged. The medical men of the Hospital who are likely to lose their appointments as lecturers in the Charing-Cross School, are opposed to the union. Into this Hospital several Poles in the most destitute state have been received, but when fit for discharge, starvation stares them in the face. They have no homes to go to. The officers of the establishment ask what is to be done with them, or what can be done for them?

* A Practical Treatise on Urethritis and Syphilis, including Observations on the power of the Menstruous Fluid, and of the discharge from Leucorrhœa and Sores, to produce Urethritis. With a new Classification of Venereal Eruptions, and a proposal of a substitute for Mercury. By Wm. Henry Judd, M.R.C.S. &c., London. Hightley. 8vo. pp. 568. With coloured plates.

CORRESPONDENTS.

Civis has not framed his questions very physiologically. They cannot, therefore, be answered in direct terms. The quantity of air inhaled continually varies without voluntary exertion. It may also be increased at pleasure; but not necessarily with good effect on the health. Changes of air continually work improvement in the whole system. The lungs are peculiarly adapted to suffer

the process of imbibition, and resort has frequently been had to them as media for administering remedial agents, but as yet, without marked and extensive advantage. It is not worth while to agitate the question (except in one or two diseases) while more obvious and less delicate channels of communication are readily approachable.

Mr. Sopwith will perceive, by the contents of the last week's LANCET, that his first was in print before his present letter was indited. The publication was unavoidably delayed from want of space.

A correspondent complains of "a custom," adopted by a lecturer at the West End, "during this course of lectures, of occupying a large portion of the time of his audience, by calling over the names of about a hundred students two or three times a week." He states that the practice is a "source of great annoyance to the majority of the class, whose attention is thus taken up instead of having it devoted to instruction." Another correspondent regards the "custom" as one adopted "with a view to displaying an array of names, of which the majority are not likely, for very good reasons, to find owners in the room. The class," he adds, "would be obliged by the abandonment of the practice."

Gammal may be assured that his friend labours under an egregious deception. The results described are impossible. We should advise the party to state his case, orally, to some respectable medical gentleman residing in the neighbourhood, who, if the aberration from a state of health be not of the intellect, conviction of the absurdity of his impressions must follow.

N. If the practitioner who made the charges, be qualified, legally, to practise as an apothecary, he would be enabled to sustain his charges in a Court of Law. At any rate, the lady would be placed in a worse position than the one she now occupies by resisting the payment of the demand. On the "hardship" of the case we cannot express an opinion.

To the Correspondent who dates his letter "Tuesday morning"—As the matter has been brought so directly under our notice, we will examine the production, and next week state the result. It certainly, however, was the business of our Correspondent to prevent, in so brief a compass, the chief sources of complaint.

ERRATUM.—Page 608, of this Number, col. 2, line 17, for *compressed*, read *comprised*. Page 611 line 27, for *a ligament*, read *ligaments*.

Observations for December,

Thermometer. Highest, 49.50, on the 1st; Lowest, 1, on the 25th; Mean, 31.50136.—Barometer. Highest, 30.78, on the 23rd; Lowest, 29.06, on the 1st; Mean, 29.80634.—Number of days of rain, 9; Quantity in inches and decimals, 0.2625.—Winds. 5 East; 2 West; 2 North; 1 South; 5 North east; 6 South east; 7 South west; 3 North-west.

In relation to the prevalence of certain diseases, as connected with atmospheric influence, it may be observed, that fever of an adynamic type, not strictly amounting to what is usually denominated typhus, with the exception of a few cases, has for some months prevailed in this neighbourhood. The inflammatory affections of children have also formed a large portion of the existing maladies, during the same season of time.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE IX.

LESSONS OF INTELLIGENCE IN CEREBRAL HEMORRHAGE.

GENTLEMEN,—Lesions of intelligence form the next part of our subject. Like lesions of motility and sensibility, they should be divided into such as precede the hemorrhage, and such as occur after it has taken place. In most cases of cerebral hemorrhage, the individual enjoys the faculty of intellect undisturbed up to the very moment of the attack. There are no premonitory symptoms on that side; however, in other cases, we observe some change in the intellectual faculties which precedes the invasion of the disease by a greater or less interval. Thus the intellect seems lazy, and incapable of any effort. The individual seeks repose of his mental faculties, and has a constant tendency to sleep, from which he is with difficulty roused; others, on the contrary, exhibit an extraordinary degree of irritability and excitement. Thus we have seen an individual in whom the access was preceded by great physical agitation and constant desire of motion; it was impossible for him to remain at rest for a few minutes together; again, others become cross and quarrelsome a few days before they are attacked, and give themselves up to violent fits of passion, resembling almost mania. It is not easy to account for this variety in the disorders of intelligence preceding apoplexy. We are disposed to refer them to individual disposition, without further cloaking our ig-

norance than really advancing knowledge. Some patients present diverse hallucinations of the senses; thus the memory is sometimes lost before the attack of hemorrhage: the individual for a few minutes is unable to say where he is or what he does. In other cases all the senses are implicated, and the patient falls down in a true state of coma, from which he unexpectedly recovers. We may now ask, What occurs at the instant of the effusion of blood into the brain?

How far are the Intellectual Faculties modified during the actual Effusion?

In some cases the intellect remains intact amidst the trouble of the other functions. It is not certain, as authors say, to find the intelligence abolished at the instant of effusion. Cases have been observed where the sensibility and power of motion were completely destroyed, yet the mental faculties remained untouched, and this especially takes place when only a small portion of the cerebral substance has been compromised in the lesion. Sometimes the intelligence becomes more weak and dull in proportion as paralysis affects the limbs; the patients become stupid; their language is incoherent and unintelligible, but consciousness still remains. Finally, in some cases, the loss of intelligence is, as you all know, complete, and the patient lies in a state of the most perfect coma, from which no kind of excitement can rouse him, or into which he quickly relapses, even if he shows some feeble indication of remaining sensibility. Do the different states of intelligence, during the moment of an apoplectic attack depend upon

Differences in the Seat or Intensity of the Hemorrhage?

Are the intellectual faculties more subject to lesion when the injury resides in one part of the brain than in another? In a word, does pathological anatomy furnish any sufficient data for localizing the intellect, or any one of its numerous faculties? It seems to me to be established, that the various conditions of the intellectual power during cerebral hemorrhage, depend much more on the intensity of the effusion than on its seat. Whichever the hemorrhage has been

intense or extensive, the intelligence is abolished, no matter in what region of the brain the lesion may be situated. Again we may ask, Does the modification or loss of intelligence occur only in cases where the hemispheres of the cerebrum are engaged in the lesion? This is a point sustained by several physiologists, who attribute the acts of intelligence to the cerebral hemispheres and their convolutions. But what do facts teach us? That complete loss of consciousness, and, of course, annihilation of all mental power, may coincide not only with hemorrhage situated in all possible points of the cerebellum, but also exists in cases where the effusion has struck another organ than the cerebral hemispheres. This latter fact has been frequently observed. We need only call to mind the analysis which we made during the course of our last lecture, of thirty-two cases of hemorrhage into the substance of the cerebellum; in several of these, the intellectual faculties were more or less abolished, although that part of the brain to which their manifestation is commonly attributed remained intact. When the mesocephale (the pons varolii) is the seat of hemorrhage, in what manner is the intelligence modified? Does it suffer as when the cerebrum and cerebellum are the seat of lesion? Certainly, and even in a still more marked degree. In all the cases that have been observed of hemorrhage into the substance of the pons, the action of the intellectual faculties was suspended, because lesion of this central reunion of the brain, cerebellum, and chord, is always accompanied by more or less complete and prolonged coma.

We may lay it down as a general principle, that

Hemorrhage of the Spinal Marrow,

into any portion of it, does not give rise to modification or abolition of the intelligence; this is readily conceived: however, the rule admits of some remarkable exceptions. In a few rare and curious cases, effusion into the superior portion of the chord has produced a reflected effect (*retentissement*) on the brain, from the law of mutual association, by which all the various parts of the nervous system are linked together in one harmony and in unity of action. A case of this kind, which deserves peculiar attention, has been cited by Dr. FARRÉ in his inaugural dissertation for the year 1832 ("Propositions and Observations on several points of Surgery and Medicine," No. 153). Here the patient, a man advanced in life, was carried off by an attack of apoplexy, accompanied by loss of intelligence, of motion, and of sensation, and, in a word, with all the symptoms of extensive hemorrhage into some portion of the brain; yet after death no other lesion could be discovered than a

moderate effusion into the substance of the anterior pyramidal bodies on the left side.

We have now passed in review the various modifications which the mental faculties present, either before the occurrence of the hemorrhage, or at the moment it takes place. It now remains to consider the state of intelligence

After the Effusion of Cerebral Hemorrhage has been completely established.

In cases where the hemorrhage is very violent, coma persists, the intelligence is absolutely abolished, and death soon overtakes the patient in this condition. When the effusion is less extensive, the state of coma generally disappears after a longer or shorter interval, leaving the intellectual faculties in various degrees of integrity. In a very small number of cases, the patient recovers the perfect use of his mental powers, but this unfortunately is a rare exception. In a great majority only a part of the intelligence is restored, and that gradually; effusion once accomplished, leaves traces that cannot be perfectly effaced from the mind, the habits, or the passions, of the individual. Thus, in general, after the occurrence of cerebral hemorrhage, we observe some weakness of the intelligence, and this in patients who had not lost it during the instant of the attack; the powers of the mind are here evidently reduced; the patient is unable to apply himself to any serious mental occupation; profound meditation is fatiguing, and even injurious; in a word, the intellect, attacked at its source, is incapable of any exertion beyond that necessary for the most ordinary occupations of life. There are other patients who are not so happy. In some cases the alteration of the intellect is still more grave; the individual is not so fortunate as to recover even a portion of his mental faculties; thus we see a certain number of persons, who remain in a state of the most wretched imbecility or idiocy after the first symptoms of cerebral hemorrhage have been dissipated; animal life returns, but the mind is gone for ever; it is rarely that this state ameliorates; the deprivation of the intellect generally increases up to the moment of death. In the moral conditions which thus accompany effusion of blood into the brain, I have sometimes had occasion to witness a curious modification of the character; the individual, reduced to a state of complete infancy, bursts into tears at the least contradiction; even when spoken to with kindness, he sometimes cries and weeps without our being able to discover any immediate cause for this manifestation of his ordered sensibility. Others, again, fall into an acute state of mental derangement; instead of imbecility it is mania, which declares itself as a consequence of apoplexy; these cases are rare, but not without example; some patients are more or less affected with

with a febrile delirium, similar to that so often seen in connection with inflammation of the contents of the cranium, and in these cases we probably have either encephalitis, or inflammation of the membranes clothing the affected hemisphere; the delirium, then, may be regarded rather as a complication than a consequence of apoplexy. The intelligence may not only be lost, or weakened *en masse*, if we use the expression, but any one part of it may be more or less modified. Thus certain patients, after an attack of cerebral hemorrhage, preserve their usual degree of judgment, of wit, of imagination, &c.; but the memory is completely lost; in other cases, again, the memory is only partially attacked; the individual remembers everything, for example, except the names of things; he cannot call to mind a single substantive in his native language. We shall return to this curious point in the history of cerebral disease at a future time.

Affections of the Speech.

In our last lecture, we saw how the power of speech was sometimes completely destroyed by effusion of blood into the hemispheres of the brain. In the cases thus alluded to, the phenomenon depended simply on paralysis of the muscles which move the tongue, the chief mechanical instrument of articulation; the aphony then was a symptom of paralysis; but language requires not only the action of the tongue (for were this not the case, all animals being possessed of that organ, should speak), but in addition to the power of moving the tongue a certain action of the brain that dominates the muscular action, a guiding influence which co-ordinates the movements of the tongue and larynx, and gives rise to that harmony which is necessary for the production of speech. It is certain, then, that a peculiar portion of the brain is destined to regulate the formation of articulate sounds, and when that part is injured, we have a species of aphonia quite different from that formerly alluded to. In some cases of cerebral hemorrhage, we have complete loss of speech; in others the motions of the tongue remain free, and the brain preserves its power of directing these motions; this proves that we have something altered in the one set of cases, which, in the other set, remains intact; but what is this something? what is the nature of the alteration upon which the loss of speech, in certain cases of apoplexy, depends? A distinguished professor of the school, M. BOUILLAUD, has attributed the formation of speech to the anterior extremity of each hemisphere, because, in all the cases he had occasion to observe, where the power of speaking had been lost during life, the lesion was found in that portion of the brain. This opinion, supported as it is by the opinion of M. BOUILLAUD, and some other physicians, requires examination; but

how are we to resolve it? By an appeal to facts; by an analysis of such cases as have been published by others, or observed by ourselves, where the lesion resided in the portion of the cerebral hemispheres described by M. BOUILLAUD as the instrument of speech.

I have found thirty-seven cases of this kind; thirty-seven where the lesion was confined to the anterior lobes. Now, of these thirty-seven, the power of speech was completely lost in twenty-one cases, and preserved in sixteen. This disproportion is as you see not very great, and hence we conclude that lesion of the anterior extremity of the hemisphere does not necessarily bring with it loss of the faculty of speech. However, we should remark that, this does not prove strictly that the power of employing language does not reside in these anterior lobes, for, perhaps, in the sixteen cases we have cited, the lesion was small, and the minor degree of intensity may possibly explain the absence of the functional disorder.

Again; I have found seven cases where the anterior lobes were intact, the lesion residing exclusively in the posterior, yet here the loss of speech equally existed. Finally, we collected seven more observations of loss of speech with effusion into the middle lobes of the hemispheres.

After reading these cases, which you will find noticed in the fifth volume of our "Clinique," it is impossible not to conclude that loss of speech may occur with the existence of the lesion in very various portions of the brain. You will also find in the same book a case, which though we have frequently quoted it, we shall mention again because it is a most remarkable one. The subject of this observation was a female 80 years of age, who presented herself at our ward in *La Pitié*. Three years before, she had been seized with loss of speech, but no other symptom of any consequence was observed. When we saw her for the first time, complete aphony existed, yet the patient could move her tongue in all directions, and thrust it out whenever she was desired; the intelligence was intact, and the faculty of sensation and of motion remained free in the superior and inferior extremities. This patient sank gradually, and died with symptoms of pulmonary congestion. After death we found a ramollissement of the posterior extremity of the corpus striatum on the left side, not larger than a good-sized pea; a similar lesion, nearly identical in form, colour, and extent, with the former, occupied the centre of the nervous pulp, the centrum ovale of Veussenius.

Thus you see, on the authority of facts which are irrefragable, that loss of speech may coincide with a lesion of the middle or posterior lobes, while on the other hand the power of speaking is not abolished with a

considerable alteration of the anterior lobes, the parts described by the physiologists we have alluded to as being the instrument of speech. This conducts us to an explanation of the reason why so many different theories have been formed as to the organ of speech in the brain. Each observer, struck with the coincidence of a certain number of facts, has built up his theory upon them, to the exclusion of all others; but they have commenced to generalize too soon. Thus M. RECAMIER thought that loss of speech coincided with lesion of the middle lobes of the cerebrum. M. SERRES, with alteration of the corpora striata, because he saw a few cases in which the patient was unable to speak, the effusion having its seat in that part. Finally, M. BOUILLAUD, as we have already said, placed the instrument of speech in the anterior lobes. I fear, that all these conclusions are premature; they cannot evidently all be correct; they appear premature, because not only is the faculty of speech abolished with lesions situate in various portions of the brain, but this symptom occurs when the lesion exists elsewhere. Thus M. LALLEMAND (Letter 2, page 134) mentions a remarkable case in which the power of speech was completely lost, although the lesion, a ramollissement, was situate in the left lobe of the cerebellum. From these different considerations we conclude, that here, as in a thousand other cases, it is impossible to localize the seat of language from pathological observations.

In our last lecture we saw how hemorrhage of the nervous centres was accompanied by various alterations of the intellectual faculties, of sensation, and of motion. The functions of nutrition also are more or less modified; let us now examine these: and first for digestion.

The Digestive Functions

are in general but little influenced by the occurrence of apoplexy. There is one effect, however, which we may observe in many cases, viz., a more or less obstinate constipation of the bowels; the muscles of the intestinal canal and rectum in particular, do not act with their accustomed energy, and even the mucous membrane seems deprived of a portion of its sensibility; hence drastic purgatives often fail to produce evacuations. The state of the circulation also presents certain troubles, but as they follow nearly the same laws for apoplexy as for cerebral congestion, we refer you back to what has been already said on the latter subject.

The State of the Pulse

in cases of cerebral hemorrhage is extremely variable, and no general rule can be laid down for the changes which it may present. In some cases, at the moment effusion takes place, the pulse is full and strong;

in others frequent; however, it is oftener slow than quick: finally, in other cases, the pulse is feeble, soft, and easily compressible under the finger. These diverse conditions are not necessarily connected with the immediate disease, but depend, rather, perhaps, on an antecedent state of the circulation, or on individual dispositions. The state of

The Capillary Circulation

presents itself with several differences. During a length of time it was said that if the patient's face was red, the conjunctiva injected, the figure swollen, &c., the case belonged to what was denominated sanguineous apoplexy. On the contrary, when the face was pale, we had to apprehend a serous apoplexy: we cannot allow these distinctions in the present state of the science. Several patients who have died from true effusion of blood into the substance of the brain, have presented a remarkable paleness of the face. This is by no means an uncommon occurrence, and shows that symptoms taken from the state of capillary circulation about the face are not to be relied on. We may conclude by remarking, that amongst the phenomena which precede or follow cerebral hemorrhage, we sometimes observe small effusions of blood underneath the ocular conjunctiva, or a more or less copious hemorrhage from the mucous membrane of the nares.

Respiration

is certainly the function of nutritive life which most frequently undergoes modification in consequence of cerebral hemorrhage; but in many cases the respiratory organs remain quite free from derangement. Thus when the effusion of blood is slight, occupying but a small portion of the nervous pulp, respiration is not modified in any remarkable manner; on the contrary, when the lesion happens to be seated in the substance of the mesocephale, the organs of respiration are affected much sooner, even though the hemorrhage may not be considerable, and the same remark applies to the spinal marrow. When the lesion of the cerebral hemispheres is very extensive, when a large quantity of blood has been suddenly effused from the vessels of the brain, then the respiration is gravely compromised, and at once assumes that peculiar character so generally known under the name of "stertorous respiration." This latter phenomenon is one of a dangerous nature, and in most cases denotes the approaching death of the individual struck with apoplexy. It probably depends on a lesion of the posterior gastric nerve, or, at least, in a derangement of its function produced by the general injury of the brain. Experiments teach us that if we irritate the eighth pair of nerves in animals, the respiration soon becomes

* embarrassed, the pulmonary circulation interrupted, and the lungs themselves surcharged with blood. Now this is exactly what happens in severe cases of apoplexy, where the patients almost universally die from embarrassment of the respiration. Remark, however, that the peculiar state of the respiration to which we now allude does not of necessity accompany all cases of cerebral hemorrhage. You will meet with several examples of the contrary, and would fall into error were you to conceive that stertorous breathing is a fixed symptom of apoplexy of the brain. How far are

The Secretions

modified by hemorrhage of the nervous centres? Upon this point we have very little to say; in fact, nothing constant has been observed of sufficient importance to merit a particular examination. In our last lecture, when treating of paralysis, we touched upon the retention of urine which sometimes occurs in consequence of apoplexy; we pointed out the necessity of attending to the state of the bladder and intestinal canal. It is useless to repeat what we have said upon that occasion.

We have now successively reviewed the influence exercised by hemorrhage of the nervous centres on the different acts of animal and organic life. We have, in order to complete the subject, a few observations to offer on the phenomena presented by

The Reproductive Organs.

Physiologists were long ago struck by the fact, that in certain cases of cerebral hemorrhage, the patient exhibits a symptom that would seem rather to belong to perfect health; this symptom is erection, which, as I have just said, has been noticed in connection with apoplexy for many years, although no explanation was attempted to be given for this unusual phenomenon. Certain authors, indeed, compared the erection which manifests itself occasionally in patients attacked by apoplexy, to the phenomena of strangulation, and referred this apparent stimulation of the genital organs to a sort of asphyxia,—to a reflux of venous blood,—to a profound trouble of the respiration and circulation. The question remained in this uncertain state until the time of GALL, who, in his doctrine of the localization of faculties, placed the regulating power of the genital organs in the cerebellum. This theory has since then been received with a considerable share of favour, and many physiologists will now tell you that if symptoms of irritation about the genital organs manifest themselves in the course of any disease, the chief seat of the lesion, or irritating cause, is to be found in the cerebellum. However this may be, the coincidence of erection, or other symptoms of excitement of the generative organs, with

effusion of blood into the cerebellum, has not been frequently observed. We are acquainted with only seven cases of this kind where erection or other signs seemed connected with apoplexy of the cerebellum; while, on the other hand, the same phenomenon has been seen accompanying hemorrhage in various other parts of the cerebro-spinal axis. It is a remarkable circumstance that in the seven cases of hemorrhage of the cerebellum to which we allude, the effusion always existed in the middle lobe; nowhere else. Of these seven, six have been published by M. SERRES, either in the *Journal of Physiology*, edited by M. MAGENDIE, or in the second volume of his *Anatomy of the Brain*.* I cannot just now call to mind which. The other was observed by M. GUIOT,† and in this also the lesion occupied the middle lobe. We may cite one of M. SERRES' cases as an example. The subject of the observation was a female 70 years of age: she was struck with apoplexy, and although at this advanced period of life, her menstrual discharge returned at the instant hemorrhage took place. After death a coagulum was found occupying the middle lobe of the cerebellum. The genital organs presented even a greater degree of erythsm than is usually seen at the period of menstruation; the uterus was filled with coagulated blood, and the inner surface of the fallopian tubes, together with the ovaries, were excessively vascular and injected. You must now be struck with the coincidence in all these cases between the symptoms and seat of the lesion. In all, the effusion took place into the median lobe. We do not find a single example on record of erection, or any other excitement of the generative organs, being produced by hemorrhage into either of the lateral lobes. This circumstance is remarkable. However, we have to observe, that whenever hemorrhage to any extent takes place into the substance of the middle lobe of the cerebellum, this part of the organ is naturally distended, and, from its position, must exercise more or less pressure on the superior portion of the spinal marrow. Hence we are unable to say with certainty, whether the phenomenon of erection &c. may not depend on this latter cause, as well as on the actual lesion of the cerebellum. There is something in this subject that is not very easily explained or understood, something that disagrees with our notions of disease in general. Is it not strange that the accident connected with the reproductive organs should be diametrically opposed to what we see taking place in all the other systems? The general phenomena

* These six cases are to be found in the "Anatomy of the Brain." Five refer to males; three were of erection; the sixth is that of the female whose case is noticed by the lecturer.—Rep.

† Clinique des Hopitaux, t. I, p. 70.

of cerebral hemorrhage are passive: in all the other apparatuses we have signs of inaction, of paralysis; but here, on the contrary, there is a state of action, a bizarre excitement at the moment the individual is withdrawn from all intercourse with the external world.

The question now before us is a complex one, and not to be resolved by a few experiments, or by a few examples drawn from pathological anatomy. It is certain that phenomena of the same nature as those under discussion may occur when the lesion is situate far from the cerebellum. Thus erection, ejaculation of the seminal fluid, &c., have been observed in connection with myelitis, with inflammation of the cerebral hemispheres, and several other disorders of the cerebro-spinal axis not immediately implicating the cerebellum. M. PINAULT presented to the Anatomical Society the case of an individual in whom the spinal marrow had been violently contused by luxation of the 5th from the 6th cervical vertebra: here there existed perfect erection for more than six hours. M. SEGALAS introduced a pointed instrument into various parts of the vertebral canal, irritating the middle and inferior portions of the spinal marrow, and erection and a discharge of semen were produced. Finally, atrophy, ramollissement, and various other diseases of the cerebro-spinal axis, are occasionally accompanied by accidents of the generative system. However, we cannot pursue this question any further; we do not profess physiology; our business is to investigate the morbid phenomena of disease, their causes, symptoms, and treatment. Let us therefore turn from this digression.

the mode of treatment I pursue; and also of pointing out to you certain errors which, in my mind, too generally prevail upon both these subjects.

In the first place, let me recall to your minds the particulars of the case to which I have alluded. When this child, who was about one year and a half old, was admitted, she presented a very wretched picture, but one which, I regret to say, is not unfrequently seen among the lower orders of this city. She was covered with old and dirty rags, had an emaciated, shrivelled, and decrepid countenance, a tumid belly, and limbs so small, that they appeared not to have developed themselves since the moment of birth. She seemed in pain, and kept constantly writhing in the arms of a wretched-looking woman, her mother. Although it was evident that the infant was a mass of disease, the mother simply directed our attention to a prolapsus of its anus of an unusual length. I mention this to show her insensibility to a state of general disease of her child, which would necessarily terminate after a few days in death. The tumour which the prolapsus formed, and which is well represented in this drawing,

CLINICAL LECTURES

ON

SURGICAL CASES,

DELIVERED IN 1836 AT THE

JERVIS-STREET HOSPITAL, DUBLIN,

BY

WILLIAM WALLACE, M.D., M.R.I.A.,

Surgeon to the Hospital, and to the Infirmary for Diseases of the Skin, Venereal Diseases, and Diseases of the Urinary and Genital Organs.

PROLAPSUS ANI.—ITS PATHOLOGY AND PRINCIPLES OF TREATMENT.

I wish to call your attention this morning to the case of the infant who has recently died while labouring under the state called "prolapsus ani." It will afford me an opportunity of explaining to you the views which I have long entertained respecting the pathology of this disease, and

was nearly four inches long, its diameter at the anus being about two inches and a half, and at its free extremity not more than an inch. The skin, or common integument round its larger end, was, to the extent of about a quarter of an inch, of a livid or purplish-red colour, and separated from the mucous surface of the prolapsed bowel by a fissure about half an inch deep, and so sharp, or so acute, that it presented, when pulled open, the appearance which would be produced by a section with a sharp knife. About two inches and a half of the tumour, or more, extending from this fissure, had a soft pulpy surface of a crimson colour, covered by a viscid coherent mucous secretion, which gave to the part a glossy appearance, and through this a quantity of a more watery fluid exuded, but not from any visible pore. This tumour, yellow,

crimson surface, extended further on the lateral than on the anterior or posterior aspect of the tumour, and farther anteriorly than posteriorly. The remainder of the surface of the tumour, or that of the smaller extremity, had a less smooth and uniform appearance. It was paler, as if less vascular. It was somewhat irregular, as if thrown into folds. In short, it presented an appearance so different from the remainder of the surface, as to force one to conclude that the structure of the two portions of the covering mucous membrane must be different, and this is the point which I wish you to remember. The paler surface was sunk below the level of the more coloured and more vascular surface. This inequality was not, however, owing to any destruction by an ulcerative process, for it presented an appearance, merely as if the vascular surface was more loose, more pulpy, more velvety, and therefore more in relief, than the paler surface. The small end of the tumour had a rounded form, or oval, placed transversely, with a depressed centre leading into the cavity of the bowel, and on the whole was not unlike, in its shape, the os uteri. The whole mass or prolapse felt firm and elastic, or like a tumour composed of erectile tissue. The orifice, or opening which was in its small extremity, was ulcerated, and so narrow, that it barely allowed the end of my little-finger with pressure to pass in. When the finger entered about an inch, it reached a large sacculus, in which it could be moved about so extensively, that I could not feel the walls of the intestine. The child strained almost constantly, and every now and then there escaped some flatus, with which there squirted out a minute quantity of a slimy substance, of a mottled white and brown colour, more or less greenish, and having somewhat a feculent appearance. The discharge of even a small quantity of this matter seemed to be always followed by momentary relief. During the effort to discharge, the tumour was increased in tension and in size, and as soon as the effort subsided, it became more flaccid and less prominent, so that it might be said to be constantly and alternately projected and retracted. This appearance was not, however, so much owing to any portion of it entering into or escaping from the pelvis on these occasions, as to its increase of tension and subsequent relaxation, and this seemed to be caused by the difficulty experienced in the expulsion of the flatus and mucous feculent matter.

The mother admitted that the child had had this prolapsus for several months; that for the last six weeks the bowel was almost constantly external to the anus, for it returned as soon as reduced, and that latterly she had not been able to reduce it at all. Having applied the nitrate of silver (the mode of doing so is afterwards explained), I

attempted reduction in the manner in which I always reduce such cases; that is, by causing the orifice or central portion of the tumour to be pushed up first; and it was quite evident, that the efforts made in reduction, so far from giving any uneasiness to the child, seemed to afford it much comfort, and to tranquillize its moans and straining paroxysms. My attempts succeeded without difficulty, and I may say, contrary to my expectations; for the tumour was so large, felt so firm, and the child's straining was so constant, that I did not expect that the bowel could be passed into the pelvis.

On making an examination of the rectum after reduction, the orifice of the anus, and the gut immediately within it, were so wide, that I found no difficulty in passing, to the extent of two inches, two or three of my fingers, and in turning them in the portion of the rectum immediately within the orifice of the anus. The portion of the gut which thus easily admitted my fingers, was that which had formed the covering of the large end of the prolapsus, and which was now returned to its natural situation. Higher up than this relaxed portion, the bowel presented to my touch a firm and undilatable sensation, and when I passed my finger into this portion, I found it to be in a tight passage, the end of which I could not reach. I also found considerable difficulty in passing this indurated portion up into the pelvis, for there seemed to be some pressure downwards on it.

After the reduction of the tumour I directed two drops of laudanum to be given to the child, and afterwards she slept quietly for several hours; which, as I was informed, she had not done for many weeks previously.

Attention was, on my next visit, directed to the laying down a plan for the restoration of the digestive organs of the child, by food and by appropriate medicine. My efforts were, however, fruitless, as, indeed, was to be expected; for although the infant seemed much relieved, and although the prolapsus never returned further than to show a ring of mucous surface at the orifice of the anus, the state of emaciation and wretchedness continued to increase, and in eighteen days after admission she died; her death being preceded, for a day or two, by a tympanitic state of abdomen, with considerable pain on pressure, great thirst, and occasional vomiting.

On dissection, the large intestines were found slightly glued in several places to each other, and to the surrounding parts, and in separating the adhesions it was evident that feculent matter had been effused, and become surrounded by glued surfaces. On opening the large intestines, their surface was found covered thickly with ulcerations, some of which had destroyed the whole thickness of the tube, and hence the fecu-

lent effusion. These ulcerations were more numerous as we approached from the cecum to the sigmoid flexure of the colon. The upper portion of the rectum was found sunk, or slightly invaginated in the middle portion, but was easily drawn up out of it, there being no adhesion between them. The rectum and the sigmoid flexure of the colon were now removed from the subject, and in doing so, I had occasion to remark that the sphincters of the anus were so elongated, as to form a much wider opening than could be considered natural to so young a child. Here is the rectum and lower part of the colon laid open, and here is a drawing of them :—

Here you observe a very prominent ridge in the upper part of the rectum, at which part you see that the bowel is quite contracted and strictured, and that this contracted state is upwards of an inch long. You also remark that the intestine above the contraction is greatly dilated, and, as it were, sunk round the narrow contracted portion, so as to form a sort of cul de sac. You also remark that this contracted portion is ulcerated, and hard, and thick. The gut nearer the orifice of the anus than this, is free from ulceration, is contracted in its length, and thickened, and far more vascular than either the narrowed portion or the portion above it. It is evident to you, I am sure, that the vascular portion of the intestinal surface formed the outward covering of the prolapse, that the contracted portion formed its orifice, and that the superior dilated portion was the part into which my finger passed, when it had penetrated through the orifice of the prolapse. It is also evident that the immediate cause of death, was the discharge of the contents of the intestines into the cavity of the peritoneum through some of these ulcerated openings, and the inflammation consequent thereon.

Although I have been minute in my re-

marks, I hope you have carried along with you all I have said, for this is necessary to enable you to comprehend the mechanism of this diseased state, or the manner in which it occurs, and the principles which should regulate its treatment. But, before I speak of this mechanism, I must beg of you to recollect certain facts relative to the rectum in its natural state.

You know that the name of rectum is given to the lower part of the large intestines which extends from the upper outlet of the pelvis to the anus, and in adults measures, in general, about ten inches. It may be said to consist of three portions, a superior, a middle, and an inferior portion; and each of these portions has a direction, a structure, and relations, peculiar to itself. The superior portion, which resembles more than either of the others the upper division of the intestinal tract, is characterized by its being covered by peritoneum, which forms for it a fold, called the meso-rectum, and connects it to the back of the pelvis; by its comparatively cylindrical form; by its projecting loosely, in some measure, into the cavity of the pelvis; and by its direction, which is from above downwards, and slightly from left to right. It forms more than half of the whole length of the rectum, and extends from the sigmoid flexure of the colon, or from the brim of the pelvis, to the line where the intestine is destitute of a peritoneal covering, or to where the third bone of the sacrum joins the fourth. Where this upper portion terminates, the middle portion of the rectum commences. It is about three inches in length, is directed from above downwards, and from behind forwards, with a gentle curve. It corresponds posteriorly to the inferior part of the sacrum, to the coccyx, and to the ischio-coccygeal muscles, and anteriorly to the inferior fundus of the bladder, from which it is separated, inferiorly and externally, by the vesiculae seminales and vasa deferentia; and more inferiorly by the prostate gland. This portion of the rectum has no peritoneal covering, unless when the bladder is very much contracted; and even then there is only a small portion of its anterior surface covered by this membrane. Its structure is distinguished by the great strength of its longitudinal muscular fibres. The third, the lowest, and the smallest division of the rectum, extends from the prostate gland in a direction downwards and backwards to the anus. Its length is about one inch and a half. It is distinguished by a continuation of the mucous membrane of the upper portions of the gut, and is surrounded by a very thick stratum of circular muscular fibres, the upper part of which is called the internal, and the lower the external sphincter. The longitudinal fibres, which are so strong in the middle portion of

the intestine, do not extend upon the lowest portion. This drawing tolerably well re-

a Upper portion.
b Middle portion.
c Lower portion.

presents the form, direction, comparative size, and relations of these different parts of the bowel, and from it you may observe that they are so curved, in respect to each other, as to form a part of the letter S. But it will be found that these different parts of the rectum are distinguished from each other, not only by their directions, their form, relation, and structure, but also by the state of contraction in which they generally exist in the living body. Pass your finger within the anus of any healthy person, and you will find that it will be grasped by the bowel for a little way within the orifice; that is, as far, or nearly as far, as the inferior division of the rectum extends above this portion, the bowel is found to surround the finger loosely, or without making much pressure. This soft and lax state extends throughout the whole length of the middle portion, and exists whether the rectum does or does not contain feculent matter. If the finger be passed on still further, we shall very often meet a sort of ring, with a rounded soft surface. This is the lower portion of the upper division of the rectum, and if the finger be passed into this ring, it will experience more pressure than it did in the middle division, though less than in the lower. From these facts, and from many others which I could add, we arrive at the conclusion that the upper and lower divisions of the rectum are, when in a state of contraction, more contracted than the middle portion. For farther information on this point, I have great pleasure in referring you to the ingenious and valuable work of

my former colleague in this hospital, Dr. O'Beirne.

Let me now call your attention to the state of the rectum in an individual making an effort to expel feces, when his bowels are constipated. The lower portion of the rectum, including the orifice of the anus, is then found more or less relaxed, the length of the middle portion diminished, and hence thrown into circular folds; while the upper portion approximates the lower. If the straining be continued, some of the folds of the middle portion appear at the orifice of the anus; and if in this state of the parts a finger be introduced, we can easily, owing to the diminution in length of the middle portion, feel the lower part of the upper portion, and even pass the finger into it, when it will in general be found to be more or less contracted.

It is evident, from what I have said, that if, from any circumstance, the relaxation of the orifice of the anus, and the decrease in length of the middle portion of the rectum, with the consequent wrinkling of its coats, and the approximation of its upper to its lower portion, be excited, and continued with pressure downwards, the folds of the middle portion of the gut will escape from the orifice of the anus, producing the state called prolapsus of the anus, and which, as it exists in its ordinary degree in infants, is represented in this drawing.

It is also equally clear, that if this state increases, the whole of the middle portion of the gut will be protruded externally, the lower orifice of its upper division will, in the same proportion, approximate the anus, and in time pass through it, and thus produce the state of parts, so far as the prolapsus is concerned, which existed in the child whose case we have been considering.

It follows, therefore, that every circumstance capable of exciting inordinate tenesmus or straining, is capable of causing a prolapsus of the anus; that this prolapsus will always, in the first instance, be formed

by folds of the middle division of the rectum; and that if the disease increases, more or less of the upper division, and subsequently of the higher portions of the intestinal tract, will be inverted, unless it happens, as occurred in the present instance, and as is pretty uniformly the case, if not always, when the inversion commences in the rectum, that there exists, at the line of inversion, a spasmodic, or a permanently contracted stricture; and, under such circumstances, an increase of inversion cannot take place beyond the seat of stricture, without the greatest difficulty, or perhaps not at all.

It is also evident, in the first place, that in every case of prolapsus, where a stricture exists, as there is thereby more or less resistance offered to the escape of the contents of the bowels, those contents will be retarded above the narrow portion, and by their pressure will cause that dilatation of the gut, higher than the stricture, which was observed in this child. In the second place, that every case of stricture, whether spasmodic or organic, in the upper division of the rectum, must become a more or less powerful cause of prolapse, or, at least, of invagination to a certain extent, as the feculent contents of the bowels, not being able to pass, unless with difficulty, through the narrowed opening, the organs of expulsion will necessarily be excited to greater exertion, and thereby the contracted portion made to invaginate itself into the middle portion, approximate the lower, as I have already explained, and assist to drive the relaxed middle portion before it, through the external orifice or anus.

It is not very difficult to account for the origin of the common and erroneous opinion, that relaxation is the cause of prolapsus ani. You are aware, that in the case of the infant which we are considering, the muscles upon which the closure and support of the rectum in a natural state depend, were in an elongated and very relaxed condition, and nothing would be more natural than for an observer, who confined his attention to this state, to consider it the cause of the prolapse; but it only requires that you should watch the origin and progress of this disease throughout the whole rectum, to be convinced, that this state of relaxation is the consequence of the prolapse, and not its cause. In fact, a prolapse could not arise from such a cause. If it could, it ought to occur whenever the retaining muscles are in a state of relaxation; but it is well known that, in cases of paraplegia, where these muscles are without any tone, prolapsus does not ensue—at least from that cause.

When you read the observations of several authors, but particularly those of Mr. Chevalier, Mr. Earle, and Mr. Howship, you will be surprised that the views which I

have explained to you, respecting prolapsus of the anus, were not forced on those gentlemen by the facts which occurred in their practice and under their observation. Mr. Chevalier and Mr. Earle have described with precision a state of the rectum in adults, which shows the earliest stage of prolapsus ani. They have ascribed a relaxation of the rectum, and with this Mr. Chevalier has attributed a contraction of the anus, which produces a dilatation of the rectum, and a relaxation of the lower portion of the gut. Instead of to a contraction of the lower part, and a necessarily induced relaxing of the organs of expulsion, Mr. Earle appears to suppose that it depends upon a peculiar conformation in the length and direction of the large intestine, from whence there arises a disposition in the upper part of the rectum to enter the lower. I would wish you to read both of these gentlemen's papers, you will find Mr. Chevalier's in the *Med.-Chir. Trans.*, and Mr. Earle's in the *Med. Gazette*. It is more remarkable that Mr. Howship, from the facts which he has recorded in his work on the diseases of the intestines, did not form the opinions respecting prolapsus which I have developed. He seems to be aware of the connection of stricture with invagination or intussusception, and of the necessity of attending to the former, when we are endeavouring to cure the latter. He has also actually described a case of prolapsus ani, in which he found, after death, the upper part of the rectum contracted, and the lower dilated; but the prepossessions of his mind, instead of leading him to what seems to me to be the proper use of the fact, made him view the contracted portion of the intestine as the healthy portion, and the relaxed alone as the diseased part. I would however recommend you to read Mr. Howship's work and judge for yourselves.

In short, in every case of prolapsus, your first inquiry should have for its object the source of that intestinal irritation, which, by exciting efforts of expulsion, has been the true source of the prolapse; and the cause which in nine cases out of ten produces prolapsus in children will be so obvious that it cannot be mistaken, if attention be paid to the origin of the disease, and its accompanying symptoms. It is, in fact, a state of disorder of the whole abdominal organs, and this leads to the prolapse, not in one way, but in several. The secretions become morbid, their impression on the intestinal surface renders it irritable, and increases the abnormal actions in which the morbid discharges originated; that it excites to a still more diseased state of secretion. Hence the contents of the bowels become daily more and more morbid, and the faces in contact with them become more and more sensitive. Excitement of anus, and of rectum, and

which have for their object the expulsion of the diseased contents of the bowels; hence purging, and irregular spasmodic contractions of the whole intestinal tract, a state which never fails to excite tenesmus and straining. These morbid spasmodic contractions may occur at any part of the canal, and then become a cause of the state called intussusception—a portion of the canal passes into a portion of the intestine immediately before it. But I can find numerous dissections confirming the fact, that in such cases the upper portion of the rectum is oftener morbidly contracted than any other part of the canal, and that when there is no morbid appearance in any other portion of the intestinal tract, this portion of the rectum will be found contracted, and the corresponding part of the colon ulcerated.

Picture, then, to yourselves a child whose entire intestinal surface is in a morbid state: whose intestinal secretions are consequently also in a morbid state, whose sigmoid flexure of the colon is irritable, and perhaps ulcerated, and whose rectum at its upper part is more or less spasmodically contracted, and you will have a case of not very unfrequent occurrence, and a state of the abdominal viscera which, in nineteen instances out of twenty, precedes and accompanies infantile prolapsus ani. What must occur in such a case? On one hand, the bowels are morbidly sensitive, and their morbid contents excite them to increased action. On the other hand there is an increase of contraction of the upper portion of the rectum, and, at the same time, increase of effort of the organs of expulsion. This effort produces an involuntary relaxation of the parts about the anus, an invagination of the upper division of the rectum in the middle, and its approximation to the lower; a wrinkled state of the middle portion of the gut, and its subsequent protrusion through the orifice of the anus; while the contracted or spasmodic state of the upper division of the rectum continuing, and the muscles driving on the contents of the intestines, a dilatation of the part above the strictured portion takes place. The stricture, which was only spasmodic, becomes, from a continuance of the disease, organic; and the state is sooner or later produced which you see in this specimen. Prolapsus ani of infants, then, for, has evidently its origin in a morbid state of the surface of the intestinal tract, and of its secretions, a consequent state of tenesmus, accompanied for the most part by diarrhoea, by disease of the sigmoid flexure of the colon, and by spasm of the upper portion of the rectum. Upon this, there supervenes an invagination of the upper division of the rectum within the middle, a subsequent protrusion through the orifice of the anus, and the disease is formed. This is generally the manner in which the disease extends, and in the most affected cases, but

in these the spasmodic contraction of the rectum is followed by organic contraction, and by ulceration of the parts of the intestine still higher up, which lead either to fatal hæmorrhage, or, as in the present case, to feculent effusion into the abdominal cavity, and consequent death.

Such is the pathology of prolapsus ani. Now, I need not tell you that, when the pathology of a disease is known, the principles upon which its cure is to be attempted are evident. As the prolapsus of infants results from a morbid state of the abdominal viscera in general, and of the intestinal tract in particular, our first object should be to restore them to health by such remedies as we know to have the effect of improving their secretions and tranquillizing their movements. To enter on a detail of the mode of accomplishing these important objects would be to enter on a dissertation on the treatment of diseases of the digestive organs. The general principles must be known to you, and their particular application is not difficult. On this subject, let me recommend to you a perusal of the paper of Mr. Wardrop in *THE LANCET* of last year. Independent, however, of this general treatment, our attention must be directed to the state of the gut. The object of this attention is to remove on one hand the morbid irritability and spasmodic contraction of the upper division of the rectum, and on the other hand the relaxation of its lower and middle portions. From what I have said, you know that if the disease be recent, we shall, for the most part, have simply a spasmodic state, and consequent narrowing of the upper division, with a trifling relaxation of the lower; but if the disease be of very long standing, we shall find above, a greater or less degree of organic contraction and thickening, probably with ulceration, and below, serious relaxation. Now, it is in vain to attempt the cure of the relaxed parts, until that of the irritable parts is accomplished. How, therefore, are we to proceed to obtain the former object? The medical treatment of the morbid state of the digestive organs will assist much. But, this will not, in general, be sufficient; at least its influence will be slow; we must also act on the part locally. In the first place we must keep the portion of the large intestine above the upper division of the rectum, as empty as possible; for, whenever there is any accumulation in it, irritation of the structured portion of the gut is the consequence, straining ensues, the strictured portion exists, and the portion above becoming dilated, the mischief is increased. Secondly, we must alter the morbid sensibility of the affected surfaces. The first object is to be obtained by throwing up at regular intervals emollient injections, taking care that they pass beyond the narrowed portion; and for this purpose, it will sometimes be neces-

sary to use an unusually long pipe, or a gum-elastic tube. To accomplish the second object, I have experienced great assistance from the cautious use of a bougie; but, particularly, from the application of the nitrate of silver. By this remedy, I have succeeded in curing rapidly very severe cases of prolapse. The mode of applying this substance must vary in different instances. I expect that in the course of this session you will have frequent opportunities of seeing it used. The principle is, to act on the part with it as you would do on any other surface with the same application, when your object is to alter its morbid action. Sometimes I have rubbed the orifice of the narrowed portion with the solid nitrate, sometimes I have passed into the upper portion of the rectum, lint, impregnated with the solution, made in the proportion of fifteen grains to an ounce of distilled water. In all these modes of using the remedy, the lower portions of the gut are more or less acted on, and this I deem necessary, but I do not consider that it is sufficient to act on these portions only; the action of the nitrate must extend to the lining membrane of the upper division of the rectum.

After the digestive organs have been got into an improved state, and after the parts have been so far tranquillized that there is no difficulty in retaining the bowel in its proper situation, you may commence the employment of tonics or astringents if necessary, to improve the state of the lower and middle portions of the rectum. But I have generally found that even for this purpose the nitrate of silver is the best remedy, as far as local applications are concerned.

I have further to add, that the state of prolapsus ani never, perhaps, comes on without giving, for a long time, warning of its approach; and if attention be paid to these warning symptoms, much trouble may be saved. They consist in attacks of irritability of the bowels, with intervals of ease. The child's bowels will remain, for two or three days, confined, then a purging will come on, by which the retained matter is evacuated, and thus the parts are for a time tranquillized, to be again disturbed, after the accumulation has again taken place. In every one of these cases you will find an irritable state of the upper division of the rectum, combined with more or less derangement of the whole of the digestive organs, including the hepatic and urinary secretions; and in passing the finger up the anus, the upper portion of the rectum will often feel prematurely contracted, or will form a sort of annulus above the pouch or middle portion. When such a case of disease occurs, repair the health of the digestive organs, principally by attention to diet, air, exercise, and clothing, and keep up a regular state of bowels, not so much by the use of purgative medicine, as by throwing

in, at regular intervals, emollient injections, to wash out the bowel above the contracted or spasmed portion.

To repeat; prolapsus ani in children originates in disease of the digestive organs, which draws on in its train a spasmed state, or irregular contractions, of the whole of the alimentary canal, but particularly of the upper division of the rectum. From this there results a difficulty in the escape of the feculent matter, a consequent necessity of straining, an approximation of the upper portion of the rectum to the lower; a wrinkling of the folds of the middle portion; an escape of those folds through the external orifice; a relaxation or loss of tone in that orifice; a subsequent dilatation of the large intestines immediately above the upper division of the rectum, which has now become the seat of organic disease, with permanent stricture. Subsequently, ulceration of the lining membrane of the large intestine, but particularly of the sigmoid flexure of the colon, with great marasmus, ensues; and lastly, an escape of the feculent matter of the bowels into the abdomen, and consequent death. To cure,—improve the general state of the digestive organs, remove the local contraction and irritability of the upper portion of the rectum, and subsequently give tone and firmness to the middle and lower portions, thus terminating our treatment with the use of remedies with which practitioners too generally commence.

Were it necessary, I could adduce a vast number of facts to corroborate the views I have now unfolded. This would, however, carry me farther than my object at present, which is merely a clinical review of the case in question. Let me, however, recommend you to direct your attention to the subject, or bear it in mind, when you are reading on diseases of the rectum; and you will not fail to be more and more convinced, every step you advance, that what I have brought forward is the true pathology of this frequent and often very troublesome disease.

Whenever an opportunity occurs I will develop my mode of treating the prolapsus ani of adults also, with the nitrate of silver, and the application of this remedy to cases of prolapse or intussusception of higher portions of the intestinal canal which appear at the anus, and which differ, as I have already informed you, in no other respect from ordinary prolapsus of the anus than in the situation or portion of the bowels in which it occurs.

ST. THOMAS'S HOSPITAL.

CLINICAL REMARKS

ON A CASE OF

VOMITING WITH Hysteria.

DELIVERED IN THE SESSION OF 1886,

BY DR. ROOTS.

GENTLEMEN,—At the close of my last lecture (LANCET, No. 643, page 491), I alluded to a case of irritation of the stomach, which I designated *vomitum cum hysteria*, and I will now read the statement of the case taken down by the clinical clerk directly after the patient's admission.

Jane Simpson, aged 22, a servant, was admitted into the hospital on the 20th of August last. She states that she had scarlet fever two years ago, and has been "short-winded" ever since. About sixteen months ago, without any apparent cause, she was suddenly attacked with vomiting, soon after taking a meal. From that time she has vomited regularly every day. At first she vomited but once a day, then twice, and now she vomits in less than ten minutes after, or even in the act of, taking fluid. She feels very thirsty; her stomach generally retains solids, but never fluids. There is great heat in the stomach, the abdomen is very tender on pressure, the tongue slightly coated, edges rather red; the bowels have generally been constive; there is some pain in the head; pulse 102, and small. She menstruates regularly. There is, at the same time, a white discharge from the vagina,—some leucorrhœa.

Upon examining into this tenderness of the abdomen, finding that there certainly was some tenderness there, though no external heat was present, I thought it right to apply twenty leeches to the epigastrium, and to order half an ounce of castor oil every other day, and one minim of creosote every six hours, in a small quantity of mucilage and water. At first this dose of creosote was not sufficient. Next day, the 21st, she still vomited after taking food, and, therefore, in the evening the dose was increased to two minims, but still was not sufficient. It was therefore increased to three minims, which dose was quite sufficient. She did not vomit after taking food, and she continued free from vomiting from that time for a considerable period. Still, however, there was the tenderness, but it extended over the whole of the abdomen and thorax, and, therefore, I had no doubt that it was merely that tenderness which is so common in hysterical affections—a morbid sensibility of the sentient extremities of the superficial

nerve,—and I saw no occasion, therefore, to treat her in any respect antiphlogistically.

22. Having continued the dose of three minims every six hours, and there having been no vomiting from the date of the last report, she was directed to take the medicine only twice a day. I should tell you that there was no emaciation. She was in tolerably good condition.

On the 1st of September, having been free from vomiting since the 22nd of August, I ordered her to take a scruple of carbonate of soda, as she complained of acidity of the stomach, and ten grains of carbonate of ammonia, twice a day, with an ounce and a half of the infusion of cascarrilla bark. I left town at this period, and she appears to have gone on tolerably well, under this plan of treatment, from the 1st of September to about the 19th, when vomiting again returned, and Dr. BURTON kindly saw her for me, and he, viewing the case as I had viewed it, no doubt,—as one in which it was best to use caution,—also applied sixteen leeches to the epigastrium, and ordered her two minims of hydrocyanic acid, with a drachm of syrupus papaveris, every six hours, out of the *mistura olei olivæ*. For three or four days this had the effect of lessening the irritability of the stomach to some extent, but on the 26th she again vomited, her pulse became 100, and small, and the dose of the hydrocyanic acid was increased to three minims.

I returned on the 2nd of October, and found the report stating that she had vomited every day since the 29th, and that she felt a dragging sensation after eating; tongue still was red, the epigastrium tender, the bowels confined, and she felt thirsty; pulse 102, and small. Not attaching any importance to the tenderness over the epigastric region, as no external heat was present, I directed that the other medicines should be laid aside, and that she should take two minims of creosote, in the mucilage, every six hours; and two grains of calomel, and eight grains of compound extract of colocynth, every other night, at bedtime, as her bowels were confined. She vomited the first dose of creosote, and then ceased to vomit; her tongue became less red, her stomach less irritable, and she had less nausea, but she still complained of uneasiness in the epigastrium; and more perhaps to amuse her mind than anything else, for I had discovered that she was exceedingly hysterical, I ordered a mustard cataplasm to be applied over the region of the stomach. The creosote was persevered in. By the 9th of October her tongue had become nearly natural, but as she still complained of loss of appetite, I did not hesitate to continue two minims of creosote three times a day, and to order two grains of the sulphate of quinine with each dose of the creosote. Under this treatment she totally ceased to

vomit, and lost all irritability of the stomach, though she complained of distulence, for which I ordered five grains of the galbanum pill with each dose of the quinine, continuing at the same time the creosote. I was thus enabled to send her out of the hospital well, as regarded her stomach, but she was still the subject of occasional hysterical attacks. I should mention to you that during this period she had frequently complained of cough, and she herself entertained an idea that she had consumption. The cough, as I understood from one of our pupils, who knew something about her, had puzzled a little the medical gentleman under whose care she had previously been, and who saw nothing in it but what was hysterical. I examined her chest myself, accurately, with the stethoscope, and could discover no disease in the lungs. In fact the whole of her affections were hysterical.

Well, you saw that the creosote relieved the vomiting and the irritable stomach in the first instance, remaining well for some time, under the administration of the carbonates of ammonia and soda, and the cascarrilla infusion; but when she had taken these for a fortnight or three weeks, the vomiting returned and was not allayed by hydrocyanic acid, though it was again arrested by the creosote; and eventually the stomach recovered its power by combining the creosote with a little sulphate of quinine.

Now, as regards the advantage derived in this case from creosote, which you know is a remedy that has not been very long introduced into practice, my late colleague Dr. ELLIOTSON being one of the earliest to try its powers. At the same time that Dr. ELLIOTSON was using it, I also was administering it in the hospital; indeed I believe I was the first who brought it to this institution; and I perfectly agree with the opinion he has expressed in his paper in the *Medico-Chirurgical Transactions*, that creosote is often of considerable value in allaying irritability of the stomach, when perfectly independent of any inflammatory action, and that you cannot but do injury by exhibiting creosote whenever there is anything like inflammation in the mucous tissue of that viscus. I do not, perhaps, quite agree with him as regards its efficiency in every such case. I think it highly useful in simple irritability of the stomach, but still I am quite certain that, like all other remedies, it does occasionally fail. I am disposed on the whole to say, that creosote is entitled to hold the same rank in the *MATERIA MEDICA*, as a remedy in irritable conditions of the stomach, free from all inflammatory action, as does the oxide of bismuth. Indeed, after having used it from the first period of its being known in this country, I may say that I have not been able to do more with creosote in irritable conditions of the stomach, than I have with the oxide of

bismuth. I have used creosote and succeeded; and I have used creosote and failed, when oxide of bismuth has relieved the irritable condition of the stomach. I have used the oxide of bismuth and it has failed. I have then given creosote, and cured the irritability of the stomach. All of you understand perfectly that the oxide of bismuth, like creosote, is a remedy which no one would ever dream of prescribing except in a case of pure irritability of the stomach, unattended with inflammatory action. I agree perfectly with Dr. ELLIOTSON as respects the negative value of creosote where there is organic disease of the stomach. In one or two instances in this Hospital I have tried it. I tried it in a case in Luke's Ward, in an old man who, beyond question, had organic disease, most probably attended with an ulcerative condition of a portion of the stomach. In that case a few doses of creosote produced vomiting, which the hydrocyanic acid immediately stopped, and for a time so far allayed the irritability of the stomach, as to enable him to take such diet as the remaining power of the stomach could digest. I need not take up more of your time on this subject, but will proceed to another case,—which, though an instance of chronic disease, presented features of considerable interest.

PAROCHIAL MEDICAL ATTENDANCE.

REMARKS ON THE PROPOSITIONS OF MR. YEATMAN.—SCALE OF REMUNERATION.

To the Editor of THE LANCET.

SIR,—I could hardly have hoped for so fortunate a concurrence of events, as the juxtaposition of Mr. Yeatman's and my letter in THE LANCET of Jan. 2nd. I trust that they may induce a thorough sifting of the arguments for either scheme; and though I should perhaps leave this to the profession at large, yet I am desirous of replying to one or two of Mr. Yeatman's observations, both on his own propositions, and on the system of a payment for each case of illness; as well as to put you in further possession of the details of the latter mode of remuneration, as proposed by myself.

With regard to Mr. Yeatman's first proposition, I beg to refer your readers to the four objections stated in the second column of my letter, which I humbly conceive are decisive, as to the difficulty attending the calculation of this mode of payment.

His second proposition is excellent in principle, but I think two years' previous residence and practice, too long as a necessary prerequisite, for it would tend to shut out many a valuable substitute for a practi-

tioner, who may have neglected, and have become incapacitated for, his duties.

His third proposition is quite in unison with my own views, as to the propriety of including every thing (with a single exception, viz., vaccination) besides midwifery and trusses, in the proposed remuneration; however that may be calculated.

But upon his fourth proposal, I am quite at issue with him; I acknowledge the "proper authorities" in this is a difficult matter but the medical officers themselves nor can I see the justice or propriety of anyone else deciding on the urgency of a case of illness. Indeed Mr. Y. elsewhere allows, "that the relieving officers can know nothing of the insidious approaches of disease;" and he most truly says, that the "victims of delay" (which must frequently occur where a non-professional person is to decide on the patient's need of assistance) "might have been restored if duly supplied with the medicines and attendance in the earlier stages of the disease."

This early attention can, therefore, only be ensured by an immediate and unrestrained application to the medical officers, and the plan which I have suggested, to prevent the parish and the medical men being burdened with applicants who have no claim on parochial relief, is quite a sufficient check on all parties, viz., that the Board of Guardians should investigate the weekly list of patients presented to them by the medical officer, and declare that the medical relief afforded to those individuals who do not belong *strictly* to the class of paupers, is merely by way of loan; the regular payments for such cases being recoverable from the patients according to the provisions of the Poor-Law Amendment Act, or similar provisions to be made for this special purpose. The patient to whom such aid is lent, should be entitled to medicines and attendance for one entire week (at least) from the first application to the surgeon. By this means not only are the parish and the medical officer protected from loss, but, in the interval, prompt attendance is provided for the sick.

I have considered Mr. Yeatman's plan attentively, and am unable to discover how his scale of remuneration could be applied, if, as he proposes in his last letter, "the expense of drugs were defrayed by parishes and unions." He must surely contemplate some reduction of his scale, when he recommends this separate parochial payment of medicines.

With regard to his proposal, however stable or practicable it might prove in large towns, it would, I feel convinced, be quite the contrary in agricultural districts with a scattered population; in these cases there can be no depot for drugs, except the medical man's own residence.

Mr. Yeatman's objections to "a payment per patient" or "per case," apply only to

the vicious mode of carrying it into effect, which the Poor-Law Commissioners have adopted; for if, according to my plan, the dangerous power, vested in the relieving officer, of "ordering" medical relief, were abolished, and no limitation allowed to the number of cases for which payment is to be made, which I also most strongly contend for, I conceive that his objection would be neutralized.

In thus venturing to criticise Mr. Y.'s proposals and observations, I do so with a sense of high respect for the benevolence, perseverance, and ability, with which he has for years advocated the cause of the most suffering and helpless portion of the community.

Permit me now to show the practicability of calculating a scale of remuneration on the principles I have already laid down.

A payment for a case of illness must include two items of remuneration;—the first, a payment for drugs, &c. &c.; the second, for the time, skill, and trouble of the surgeon. The first may be readily estimated by a reference to hospitals and dispensaries &c. The Rev. C. Oxendon, of Bishopsbourne, has drawn up, with great industry, skill, and success, a "Statistical Report of the Principal Provincial Hospitals in England." The average cost of each patient in those institutions will be found in this very valuable work; I have deduced the following calculation from it:—

The total number of patients treated during one year in twenty-seven hospitals (including all except a few small and recently established infirmaries) was 90,426, of which 23,180 were in-patients, and 67,246 out-patients. The total expense of these in drugs, leeches, wine, spirits, surgical instruments, &c., was 17,969*l.*, or about 3*s.* 11*d.* per head;—in drugs and leeches only, 11,044*l.*, or 2*s.* 5*d.* per head. The first of these sums includes more than the parish-surgeon has to supply his patients with; the second, less; we may suppose the intermediate sum of 3*s.* to be nearer the mark; but we must admit, from Mr. Oxendon's impartial statement, that the expenditure in drugs in some of the hospitals has been uselessly extravagant.

I have further examined fifteen annual reports of some of the principal dispensaries in England, both charitable and self-supporting, which give a total number of patients of 26,708; and an expenditure in drugs of 1561*l.*, or about 1*s.* 3*d.* a head.

The Rev. C. Oxendon elsewhere says, "The medical expenses of an hospital in-patient are three times greater than those of an out-patient during the same time. So again, dispensary home-patients will be more expensive than those who attend personally at the dispensary. I consider 1*s.* 6*d.* per head sufficient for an out-patient, and 4*s.* 6*d.* for an in or home-patient."

A respectable druggist in Southampton supplies medicines to the patients of charitable dispensaries at 4s. per head; and another in Blackfriars, London, at 2s. 6d. per head.

But another valuable fact may be taken from St. Mary's parish, Nottingham. In the parochial dispensary, in which the number of patients annually treated (on an average of seven years, ending March 1825) was 2096, and the average annual expense in drugs &c. per head being about 1s. 6d.

Taking, therefore, these several averages as guides, we may reasonably and fairly conclude that a payment of from 2s. to 3s. per head would defray the cost of drugs. When the number of patients is great, I have no doubt that 2s. would be sufficient; while, if small, 3s. would be required.

The second item of remuneration, viz. the time, skill, and trouble of the medical attendant, is not so easily estimated, as, of course, it is more a matter of opinion. It cannot and ought not to be expected, that parochial remuneration should, by any means, be equivalent to the value of professional services. Medical men must look for their incomes to the higher and middle classes of society, and can only claim of the community an exemption from absolute loss in their attendance on the poor.

Influenced by these notions, I suggest that the *lowest* average payment for attendance *solely*, should be 1s. for each case, and this only where there are very numerous patients comprised within a small space, and close at hand to the medical officer; on the

other hand, where there are very few patients, it could not be stated at less than 3s. per case.

Again, the circumstance of distance from the medical officer, which in thinly-peopled agricultural districts entails on him considerably more labour and expense, requires a distinct and uniform charge, not only for the reason just mentioned, but as a pecuniary check on parishes appointing medical officers situated remotely and inaccessible with regard to the sick poor.

For this reason, I propose an additional fourpence per mile for each patient residing at a distance from the medical officer, whether actually visited by him or not. This arrangement would not be open to the objection properly urged by Mr. Yeatman against a charge for each journey.

Such, being the data of my calculation, deduced not only from the average estimates already mentioned, but from a comparison of many parochial salaries, I recommend the annexed scale, in which it will be seen that the lowest charge, 3s., includes, as before stated, the cost of drugs 2s., and of attendance 1s., while the highest rate of the scale comprises the cost of drugs 3s.; attendance 3s.; and distance above five miles (or within six) at 4d. per mile, 1s. 8d.: in all 7s. 8d.

The intermediate charges of the scale increase in arithmetical progression, and the number of patients in geometrical, a much more reasonable as well as more correct variation than that of Mr. Yeatman's scale.

SCALE for calculating the Remuneration for Medico-Parochial Services.

Distance of Patients from the Medical Officer being within	Number of Cases of Sickness and Accident attended in each Parish during One Year, being						
	25	50	100	200	400	800	1600
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
1 Mile	6 0	5 6	5 0	4 6	4 0	3 6	3 0
2 Miles	6 4	5 10	5 4	4 10	4 4	3 10	3 4
3 Miles	6 8	6 2	5 8	5 2	4 8	4 2	3 8
4 Miles	7 0	6 6	6 0	5 6	5 0	4 6	4 0
5 Miles	7 4	6 10	6 4	5 10	5 4	4 10	4 4
6 Miles	7 8	7 2	6 8	6 2	5 8	5 2	4 8

Example.—If the total number of cases attended during one year in any parish be 400, the payment for each of those occurring within one mile of the surgeon's residence, should be 4s., within two miles 4s. 4d., within three miles 4s. 8d., within four miles 5s., and so on.

If the number of cases be intermediate

between any of the numbers mentioned at the head of the scale, the payment to each should be altered proportionally; thus, if a medical officer had attended 150 cases, his payments would be 4s. 9d., 5s. 1d., 5s. 5d., 5s. 9d., 6s. 1d., and 6s. 6d., according to the distances respectively. The subdivision of the scale might be made yet more minute.

One column of the above scale, or some intermediate rate of payment suited for each parish, should be agreed on at the beginning of the year (perhaps according to the number of cases attended during the previous year); otherwise either party concerned might, by fraudulent management, increase or reduce the sum total paid for the same amount of labour at the end of the year.

Every distinct and different case of illness, or accident, in the same individual, however close in succession, should be charged; but, to prevent any unfair conduct on the part of the medical officer, a relapse of the same disorder occurring within one month from the date of discharge should be considered as part of the former illness.

There should be no extras, except for midwifery, trusses, and vaccination; I think I am expressing the opinion of a majority of medical men in proposing that the ordinary run of pauper midwifery cases should be managed by a female midwife; a medical practitioner attending only when called on by her. This will not only be a saving to parishes, but a relief to the profession. The charge should not be less than one guinea, with an additional allowance for mileage. Vaccination might be charged at 1s. 6d. per head, and trusses at cost price.

No practitioner should be allowed to attend paupers distant more than six miles, unless he be the nearest eligible medical resident to those paupers; when a further charge of 4d. should be made for every additional mile in each case; nor should any one be permitted to undertake the entire care of a parish or parishes, which, during the previous year, have furnished a total of above 1000 cases; nor any firm of medical men more than 1600 cases.

There is one obvious advantage in the proposed remuneration, viz., that as it provides for two clearly defined items of expenditure, they might be separated, if desired, and so afford a facility to parishes for supplying their own drugs (which, although recommended by Mr. Yeatman, could not be satisfactorily effected on his plan); for instance,—deducting 3s. for medicines from each of the payments in the first column, for 25 cases; 2s. 10d. from each of the payments for 50 cases; 2s. 8d. from each of the payments for 100; 2s. 6d. from the payments for 200; 2s. 4d. from the payments for 400; 2s. 2d. from the payments for 800; and 2s. from the payments for 1600; the remainder will show exactly the sums which should be awarded to any surgeon who might undertake the care of the poor, without furnishing the medicines.

I am not aware that I have now left any material part of my scheme unexplained, but shall be happy, with your permission, to answer any questions or observations it may elicit. I remain, your obedient servant,

Jan. 13, 1886.

RURICOLA.

THE LANCET.

London, Saturday, January 23, 1886.

THERE can be but one opinion amongst honest and intelligent men relative to the course which the Ministers should pursue in founding the new University, and that course is indicated with sufficient clearness by simply recommending that they should act upon sound principles of popular government, rather than receive with approbation the noxious suggestions and schemes of the rump of the old corruptionists. The confidence which we repose in the Ministry leads us to suspect that the CHANCELLOR of the EXCHEQUER did good-naturedly comply with an urgent request that he would receive the report made to him by the College of Physicians, and one of the Councilors of the College of Surgeons, concerning the medical department of the projected new institution; and it would appear that some dozens of simpletons have been deceived by the *ruse* which was so admirably played off upon them by the CHANCELLOR of the EXCHEQUER. The manœuvring wrong-heads were guilty of the folly of believing that the reception of the report by the CHANCELLOR would be synonymous with its adoption by that Government functionary. It is clear enough that these creatures, who are so fast sinking into professional obscurity, will catch at any straw, however slender it may be, in the hope of maintaining a little while longer even their present degraded position. No sooner, therefore, had the CHANCELLOR of the EXCHEQUER allowed three or four of the old corruptionists to be named as the individuals who should frame a plan for the medical department of the New University, than did the halls of the old Colleges resound with every possible expression of satisfaction and delight.

Every person who has had any experi-

ence of the industry and pertinacity with which the corruptionists push their interests in the government offices, must approve of the measure to which Mr. SPRING RICE resorted, in order to be ridded for a while from the entreaties of his tormentors. But for any man to suppose that the CHANCELLOR of the EXCHEQUER intended to adopt, *bona fide*, the scheme of the HALFORDIAN crew, is to cast upon that gentleman an imputation which it would be most unjust to the honour and intelligence of the minister to inflict upon him. The medical practitioners of England have not yet forgotten that it was to the head of the present Ministry that they were indebted for the success of Mr. WARBURTON'S motion for the appointment of a committee to inquire into the nature and extent of medical abuses. It will not be easy, therefore, to make those high-minded men believe that Ministers would subject themselves to the imputation of wantonly trifling with the feelings of the most useful and influential body of educated men in this country. Had Mr. SPRING RICE really conferred on SIR HENRY HALFORD, SIR B. BRODIE, DR. ROGET, and DR. CHAMBERS, the power of framing the arrangements for the medical department of the new university, he would have proved by that one act—whatever may be the extent of his classical and general attainments—that he was incompetent to execute the task which had been confided to him by his colleagues, and, moreover, that he was blind to the faults, the prejudices, and the practices, of the parties in question, and possessed of no knowledge whatever of the claims which the medical practitioners of England are at this time forcing upon the attention of the legislature. But we tell the boobies who have been deluded by the tact and discernment of the CHANCELLOR of the EXCHEQUER, that the medical reformers are now too strong to stand in fear of any ministry. The medical practitioners in this empire are upwards of twenty thousand in number, and, from their intelligence

and respectability, and, still more, from the benevolent and high-minded occupation in which they are necessarily engaged amongst all classes of the community, they exercise an influence over public opinion, which is paramount to that of the members of any other profession. It is not extraordinary, therefore, that their arguments, in any question, should receive the respectful and earnest attention of both Houses of Parliament.

Now, it happens that the members of the medical body have no particular desire to see any new medical titles awarded, which are unconnected with the rights and immunities of legally-qualified practitioners. They necessarily view with caution and jealousy, the proposal to institute a metropolitan university, wherein degrees of medicine are to be granted, because they apprehend that it will only serve further to entangle the question of medical reform, and add to the confusion which already exists on the subject of medical qualifications. At the very outset of the University question, we deprecated any fresh meddling with medical affairs until the report of the Medical Committee of the House of Commons was placed before the Legislature. Not one-third of the evidence, the printing of which must necessarily precede the publication of the report, is yet before the profession; and we suspect that the Ministers of the Crown know little relative to the inquiry, further than that the evidence has proved that the entire system of medical government must be remodelled. That such a conviction exists in the minds of the Members of the Committee, Mr. RICE and his colleagues are, doubtless, aware; but with the particular points of the evidence, the striking facts of the investigation, they are, in all probability, totally unacquainted. Who, then, shall contend that the Ministers can safely proceed, at present, in the constitution of a new medical institution? Even if we admit that they resolve to advance in their work upon principles of acknowledged justice and liberality, still, their want of acquaintance

with the defects and abuses of the old corporations, may lead them to commit many serious and fatal errors, and involve them in an endless network of perplexities. Yet, if they determine to proceed before the Members of the Medical Committee have had the opportunity of framing their report, and apply, in their emergency, to their foes—their inveterate and implacable foes—for advice and assistance, rather than to their staunch and steady friends, they will at once forfeit that respect which is now felt towards them, in a pre-eminent degree, by nineteen-twentieths of the medical practitioners of the United Kingdom.

But the conduct of the executive Government in the last session of Parliament, regarding the municipal corporations, was so distinguished for its liberality, that not a doubt can exist in the mind of any sane man, that the rotten medical corporations, in which the system of perpetual self-election is maintained, will be entirely and forever overthrown, and that in founding the new university, no similar tyrannical and unjust power will be exercised by any set of individuals whatsoever. Neither the profession nor the public are in a state of mind to be trifled with on this subject. Hitherto the Ministers have proceeded in an honest, straightforward, enlightened course of policy, and we call upon them, as they value their own honour and the best interests of the country, to recede with horror from the proffered assistance and embraces of the self-elected and sordid monopolists who have so long scourged and degraded the profession by their iniquitous conduct in the College of Physicians and the College of Surgeons.

No idle report or loose rumour will induce the profession to believe that the Ministers have deserted the cause which they have already so ably supported, and we are assured that nothing but facts of the most reprehensible character and description can induce the profession to withhold their confidence from Lord Melbourne and his col-

leagues. If Mr. SPRING RICE, however, be really desirous of obtaining for himself and his official associates the unextinguishable hatred, and the profound contempt, of ninety-nine hundredths of the medical practitioners of Great Britain and Ireland, he will call to his aid Sir H. HALFORD, Sir B. BRODIE, Dr. ROGET, and Dr. CHAMBERS, and adopt as his own the scheme of those gentlemen for governing the medical departments of the new university. The CHANCELLOR of the EXCHEQUER might then take his leave of the question of medical politics. At any rate his views on that subject would never afterwards carry with them the slightest interest, except to the most incurable, ignorant, and sordid of the plundering monopolists.

A REPORT of the meeting of medical students of this metropolis, which was held in the great room of the *Crown and Anchor Tavern* on Monday evening, will be found in another part of this week's LANCET. It was computed that from first to last there were present on that occasion 1500 medical gentlemen, nearly the whole of whom were students. A more respectable assembly, or a more interesting one, was never seen in this metropolis, and considering the degree of excitement which prevailed in the minds of the gentlemen present,—all of them labouring under the impression that they had been grossly injured and insulted at Apothecaries' Hall in the person of one of their body,—the decorum and excellent order which prevailed, evidenced the importance that was attached by the assembly to the subjects which were brought under discussion. The declaration which was then made by the medical students of London, in favour of a public examination of candidates for medical honours, is, beyond all question, the most striking fact in favour of throwing open those Halls and Colleges where medical degrees and licenses are conferred, that has ever been submitted to the attention of the legislature and the public,

In short, such a declaration must annihilate the secret system, and establish in its stead, a tribunal of unrestrained publicity.

The bold and manly bearing of the medical students of the metropolis, in thus demanding that their attainments may be fairly and openly scrutinized, must obtain for them the respect and admiration of every enlightened member of the profession. The chairman of the meeting, Mr. MEADE, conducted the business of the evening with judgment and ability, and it was gratifying to observe the deep interest which Mr. CARPUS, with his whitened locks, still manifested in promoting the welfare of medical pupils. But what attendance was there of the physicians and surgeons of the "recognised" hospitals of the metropolis? What attendance was there of those gentlemen who utter such a profusion of bonied and friendly professions in their introductory discourses on the 1st of October, — the ticket-selling, fee-catching day? What attendance was there of those *ever sincere* friends of medical students? Oh the number is easily counted. Mr. LISTON, of the *London University*, was the only hospital surgeon in London who supported the cause of the students by his appearance on the platform, and it rejoices us to be enabled to state that that distinguished surgeon received, as the just reward of his spirit and liberality on this occasion, the unanimous and hearty greetings of the entire assembly.

The views and purposes of the meeting will be found so fully expressed in the account furnished by our reporter, that we content ourselves this week with referring the profession for information and food for reflection on the highly important subject discussed, to that document.

In giving insertion to the letter of Messrs. CARMICHAEL, CRAMPTON, and COLLES, we take this opportunity of directing the attention of our highly respectable correspondent "Observer," to the contradictions of his statements which these

letters contain; and we also inform him that we have been requested to state that no petition was forwarded to the government by the "Sisters of Charity" on behalf of Mr. FERRALL, and that the remarks relative to the interference of those ladies in the election, are entirely unfounded. We have also a separate letter from Mr. CARMICHAEL, without room to insert it this week. ⁶

In a clinical lecture which was delivered a short time since by Sir CHARLES BELL at the *Middlesex Hospital*, some remarks were made on the subject of reporting clinical lectures in the medical journals, which demand from us an especial notice, and they shall receive it. Without intending to offer to this distinguished gentleman the slightest offence, we would seriously advise him to turn the current of his thoughts to any quarter rather than that of the press, or he will stand a fair chance of entering "modern Athens" as a confirmed twaddler. Some men take pains to make themselves ridiculous. Sir CHARLES BELL is one of them, and on three or four occasions in that way, his attempts have been very successful.

GREAT MEETING
OF THE
MEDICAL STUDENTS OF LONDON,
AT THE CROWN AND ANCHOR TAVERN,
On Monday, Jan. 18, 1830,
TO PETITION PARLIAMENT
TO EFFECT AN ALTERATION IN THE
EXAMINATION OF CANDIDATES
FOR
MEDICAL LICENSES AND DEGREES,
AND TO FORM A
CENTRAL STUDENTS' ASSOCIATION.

THE challenge forwarded by Mr. THOMAS SMITH to the Court of Examiners at Apothecaries' Hall, demanding a public examination in order to prove that his rejection by the Court on the previous Thursday, was not determined in consequence of his incompetency of the candidate, led to the formation of a committee of medical students to determine what steps should be taken by the great body of students in London on an occasion which was especially calculated to discuss the grievance under

which they universally laboured in consequence of the existing system of private examinations at the medical boards. The committee, it appeared, resolved on convening a public meeting of the students to take the subject into consideration, which was publicly advertised, and held on Monday evening last, at six o'clock, in the great room of the *Crown and Anchor Tavern*, where nearly the whole of the medical students in London were assembled.

The proceedings commenced by the unanimous nomination of Mr. WILLIAM MEADE, of King-Street, Southwark, to the Chair, amid great cheering.

The CHAIRMAN then opened the business of the evening in the following statement: Gentlemen, you have been called here this night by advertisements, in which it was signified that a discussion on matters of vital importance to your future welfare and interests was to take place. It will be my duty on this occasion shortly to explain to you why it was desirous to hold a public meeting for this purpose. You are all aware that near Blackfriars Bridge there exists an institution which is called the Apothecaries' Hall of London; and you are also aware that many acts of injustice have been committed by that tyrannical body of monopolists. The characters of many of your professional brethren have at various times been destroyed by the unjust proceedings in that establishment, at the examinations of students, and the question now is, whether by an unity of moral force and an appeal for justice to the right quarter on your part, you will not, after this fresh instance of injustice, attempt to prevent a repetition of oppression on the part of the offending body. (*Cheers.*) Without, then, further preliminary remarks, I shall at once state to you the facts of the case. Within the last three years I have been occupied in the duties of a private teacher in London, and have become acquainted with instances of gross injustice to medical students by the Court of Examiners in Apothecaries' Hall. The details of the examinations would sufficiently testify this fact. I shall confine myself, however, to the act of injustice which has been the more immediate cause of this meeting. The gentleman who was rejected on Thursday week, was interrogated in the strangest manner. He was first shown a prescription in which camphor and mercurial ointment were directed to be admixed. He was asked, what was the use of the camphor? He said, it promoted the absorption of the mercury into the system. The next inquiry was, how that was effected? He replied, by stimulating the lymphatics. He was then asked, did it act upon the absorbents? His reply was, that the lymphatics were the absorbents; and he also mentioned that it was partly taken up by the process of endosmosis. At this scientific

term the Examiner sneered, and so began to decry the acquirements of the candidate. He was then asked, how nitrogen got into the system? He replied, partly by the agency of respiration. The Examiner said, that there was as much given out as was taken into the lungs, therefore there could not be any taken in at all. He was then asked, did it obtain admittance in any other way? He mentioned, that it was taken in through the medium of the digestive apparatus, and said that some vegetables which are used as condiments contained a considerable quantity of nitrogen. He was asked, what these were? He replied, that they belonged to the natural order of cruciferae. He was told to name them; and he mentioned the different kinds of mustard, horse-radish, broccoli, and cabbage. Here the Examiner said, contemptuously, "Tailor's cabbage, I suppose." (*Cries of "Shame, shame."*) The Examiner soon after inquired, what was the ultimate composition of the muscles? He mentioned carbon, oxygen, nitrogen, and hydrogen; whereupon he was asked in a gruff and surly voice, whether nitrogen, therefore, did not get into the system in beef and mutton? (*Much laughter.*) Then he was asked, what was the state of the bowels in diabetes? to which he replied, that they were irregular in their action. "Constipated, Sir," said the Examiner, "constipated; how can the bowels be irregular when so much fluid passes off from the system by the kidneys?" (*Great Laughter.*) I suppose the worthy examiner considers that much fluid is essential to wash out the bowels. Mackintosh, Gregory, and Martinet, state, the two first, that the bowels are irregular in diabetes, and the latter that they are irregular, but generally constipated. The student was then asked what was the state of the pulse in nephritis, to which he answered "Quick and hard," which the Examiner instantly contradicted in the most abrupt and rough manner, by "Quick and full, Sir." (*Cries of "Shame, shame."*) Mackintosh and Gregory state that the pulse is quick and hard. Marshall Hall does not notice the state of the pulse in nephritis. He was then asked what was the treatment of intermittent fever, and he said that before the accession he would give an emetic, and mentioned the treatment recommended by Dr. Mackintosh, and which is now very generally adopted, namely, bleeding in the cold stage of intermittents. The candidate was forthwith asked, in a tone of astonishment, would he bleed? He replied that he had heard that practice strongly recommended, and should be inclined to adopt it. He was presently afterwards asked what purge he would give in nephritis, he said he would add castor oil to the enemata. "By the mouth?" was the inquiry. He said, No, because there was great sickness. What,

then, would he give by the mouth? He said two or three grains of calomel. "No, Sir," the Examiner replied, "you should give a mild purge of ten grains of the extract of colocynth and five of calomel. (*Immense laughter.*) Gentlemen, the end of all this ignorance, captiousness, and unfairness, was the rejection of the candidate. There are numerous other points in this examination, gentlemen, but I shall not speak further on it this evening. I hope I have mentioned sufficient to satisfy you, that the conduct of the Examiners on this occasion has been unjust. I promise you that the examination shall be published, supported by the very best authentication that can, under the circumstances, be given to it. Such reckless unfairness can only receive its reward by publicity. (*Hear, hear.*) I am convinced, that so long as there is a private Court of Examiners, without any means of appeal, so long will injustice continue to be perpetrated. When they improperly reject a candidate, and they are supplicated to give another examination at once, they say—"We cannot, Sir; the Act of Parliament does not permit us to give you another examination." Then it becomes our duty, if the Hall is really so precise in its observance of the law, to apply to the Legislature to give us at least good laws for examining bodies to fall back upon, with power of examining a second time, and public examinations (*cheers*); for, while they are private, you may be sure that when once a Board of Examiners has committed an act of injustice, they will not like to falsify their first decision by passing a man the second time. The second examination would, if possible, be more unfair than the first. In taking the chair to-night, gentlemen, I do trust and believe that your enemies, who are carefully watching your proceedings, will not have the power of saying that medical students cannot meet without occasioning some disturbance. (*Cheers.*) The Examiners of the Hall are now chuckling at the idea, that the students will commit themselves to-night, and that is the only ground they have for hoping to have the power of again doing you wrong. With quiet and becoming conduct, you must here protest against their injustice, and you will then succeed in your object. Your wrongs need discussion among yourselves, and the mode of redressing them will not be long unsuggested. Many are the men who have, in the course of years, been sacrificed to the injustice of this institution, men who have been fully competent to practise their profession, but who have left that Hall with aching hearts, not knowing where to hide their heads,—men who have been previously known to their fellow students and professional friends as able and well-qualified candidates, who have gone from that Hall disgraced on account of some injustice on

the part of its Examiners. (*Hear, hear, hear.*) The student is said to be rejected by a majority of the Court, but he is not, strictly speaking, rejected on any occasion by a majority. An Examiner comes to a chair for two or three minutes, hears what the candidate says, puzzles him by some question which is peculiar to the Hall (*cheering and laughter*), walks away, and is succeeded perhaps by another Examiner, who walks by, shakes his head, and cries, "A bad business," and the pupil is rejected. The Act of Parliament contemplates that at least a majority of the Court should listen attentively to the examination, and not that two or three of them should walk to and fro by the table, putting peculiar questions, and thus professing to form their opinions on the talents and competency of a man. I will tell you what is the mode of decision with one of these philosophical Examiners. He says, "When first a young man comes into the room we look in his face, and if we see that he is clever, we expect so much the more from him; but if we do not think he is clever, then we try whether he knows anything at all, or whether he can be of any use to society, and so help him on." (*Great laughter.*) Is an Examiner who judges according to physiognomies who he should sport with? Is such a man as that fit to be an Examiner? (*Cries of "No, no."*) It is too bad that the examinations should assume such a form as they do. There are four tables in the room; it is all a chance to which table a pupil is conducted, whether to Mr. Ridout's table, or somebody else's. Perhaps the other three tables are supplied by at least gentlemanly Examiners, if not very competent ones. (*A cry of "Wheeler is as bad as Ridout."*) Well, they are both very bad. (*Laughter.*) Now, of four students who may go in, three may pass through very well, but the one who falls to the lot of the fourth examiner, may, on no kind of principle that is good, fall a sacrifice to that accident, or to some private pique or spite, and have his character completely destroyed. The gentleman who has challenged the Hall to give him a public examination, had, before he went up, the full approbation of his lecturers and teachers to present himself, and he was considered perfectly competent to pass at the school to which he belonged. But there was evidently something premeditated against him, and whether by chance or design he fell into the jaws of Mr. Ridout. It is a fact, that in the very middle of his examination, his indentures of apprenticeship, which had before been received, were brought into the room by Mr. Watson, who tapped him on the shoulder, and laid them on the table, when the Examiner took them up at that particular moment to inspect. There was a reason for this extraordinary proceeding, which I shall not explain to you now, but

it affords convincing proof that you have no protection at the Hall against the most unbecoming and depressing acts on the part of the Court. Now, the object of the present meeting is to consider the best means of providing a remedy against the injustice of that body, and to protect, in future, the professional rights of the student. (*Cheers.*) Resolutions having for their object these purposes, will be proposed to you, and I am sure that you will hear with attention everything that is said to the point respecting them. As far as my endeavours can go there shall be a fair and impartial hearing afforded to every speaker who keeps to the points in question,—the examinations at the Hall as at present conducted, and the best mode of protecting the medical students of London from injustice. (*Hear, hear.*) General politics we shall wholly avoid. I ask of you a calm, quiet, and dispassionate discussion, and let not the Examiners of the Hall, or any of your oppressors have reason to say to-morrow that this was merely a meeting of riotous students. That is what they want. It is their great hope that this will be a riotous meeting. "There will be a row," say they, "the students will depart, and then what care we. The students will then have no power, and their meeting won't affect us a bit." If your enemies choose to say what is untrue, why, we can't help that. But let them have no good ground for considering that after this meeting they will actually have more unjust power over you than ever. Deceive their wishes, gentlemen, by testimony that cannot be mistaken. (*Loud cheers.*)

The following letter from Joseph Hume, Esq., M.P., was then read to the meeting, and received with very great applause:—

"To the Chairman of the Meeting. Sir,—I request that you will state, if it should be necessary, to the meeting, that I should have attended, agreeably to the request contained in Mr. Paine's letter of the 16th, if I had not had a previous engagement which I cannot avoid. Be pleased also to state that I concur in the propriety of their making application to the Government for an immediate and thorough reform in the regulations and practices of the Examiners of the Apothecaries' Company, of the College of Surgeons, and of the College of Physicians. All require to be new cast, and some intelligible system adopted for the regulation of medical education, the granting of degrees, &c., and, above all, all examinations for degrees, diplomas, or licenses, should be held in public. I hoped to have seen Mr. Warburton respecting his views for the next session. But although I know that he is most anxious to see a thorough reform in the profession, yet if you wish for relief you must endeavour to assist yourselves, and to lay before the Government a statement of the abuses of which you com-

plain, and demand that they make it part of their duty to reform the present system without delay. I shall have much pleasure in co-operating in every way in my power to obtain your object. I remain, your obedient servant,

"JOSEPH HUME.

"Bryanstone-square, Jan. 18, 1836."

Mr. PAINE, rose and said,—Mr. Chairman and Gentlemen,—I am deputed by the Committee to propose to you the first resolution, and I can assure you that I feel more than an ordinary degree of pleasure in doing so. I feel that we are now about to try to obtain the redress of one of the greatest grievances that can befall a student. We do not meet in ignorance of the tyranny that has so long been exercised at Apothecaries' Hall, when it has suited the purposes or the whims of the Examiners. We know too well that many of the students who have been rejected there, were men who were far more deserving of holding seats in that Court than those men who really occupy them, and while those institutions which affect other classes of the community are undergoing reform, why should not the Apothecaries' Hall be also reformed? Men's minds have become more expanded, and their knowledge much greater, and I am sure it is not right that men who were educated nearly half a century ago, should have the power of sitting as an irresponsible and secret board of examiners, to exercise their power over students of the present day. (*Cheers.*) We know that very many men have gone into that Hall, who have devoted years to their profession, and who possessed high intellectual attainments, have been made to bow to the shrine of ignorance. (*Cheers.*) Why should not such an institution become the subject of reformation? But I am happy to know that the days of all close corporations are numbered (*hear, hear*); and I sincerely trust, that ere two more sessions of Parliament have closed, that the present corrupt body will be totally abolished. (*Great cheers.*) I hold in my hand a letter which I have received, since coming upon these hustings, from Mr. Warburton. (*Some person here said, "That is politics."*) A gentleman behind me says I am introducing politics. I say that this is not the fact; I will not touch upon any politics but medical politics, and those are the politics which we are expressly called upon to discuss. Mr. Warburton says that he should have felt much pleasure in joining this meeting this evening. (*The same individual said "You mustn't read it. It's politics. It is private. It is to the students."*) Cries every-where from the meeting of "Read, read."

"To Mr. Paine, Secretary to the Committee, &c.—Sir,—I received this morning your letter inviting me to be present at a meeting of medical students, to be held this evening, to take into consideration certain

proceedings of the Examiners at Apothecaries' Hall, &c. As I had already formed another engagement, I could not have attended the meeting, but independently of that reason, it appears to me to be best that I should not attend it. But I always hear with pleasure that persons who feel themselves aggrieved, assemble to consider and discuss the subject of their grievances, and individually I should, without doubt, have derived much gratification from the information to be received by attending the discussion. With earnest wishes for the prosperity of the medical students of London, I have the honour to be, Sir, &c.,

"HENRY WARBURTON."

(Enthusiastic cheering followed the perusal of the letter.)

Gentlemen, I shall not detain you longer, excepting to entreat that you will universally join in the work we have begun, and I am sure if you do, that we shall soon be able to shout a joyous requiem over the remains of that despotic tribunal of injustice, the Apothecaries' Hall, which has been so execrable in its existence, and will be so detestable in its death. (*Low cheers.*) I beg to move, gentlemen, "That this meeting is of opinion that the examinations, as at present conducted, at Apothecaries' Hall, are conducive neither to the honour of the profession, nor to the protection of the public, nor are they adequate tests of the abilities of the candidates."

Mr. SCOFFER, with pleasure, seconded the resolution. Abuses, he feared, had existed in the Apothecaries' Company ever since it had been entrusted with the power of granting licenses. Young men came up to London, devoted the whole of their time to perfecting themselves to practise in their profession, went up prepared to the Hall to pass, and often, in consequence of the Examiners themselves not properly comprehending the questions which they put, were turned back. It was notorious, indeed, among medical students, that whatever the talent and scientific knowledge of the candidate, if he relied upon that for passing, without being initiated into some of the queer questions of the Hall, he would fail. (*Hear, hear, hear.*) He most cordially supported the resolution.

The CHAIRMAN then put the resolution to the meeting, when one hand was held up against it, which caused great laughter, and cries of "Let him come forward" having arisen, the dissident advanced to the platform, and was announced to the meeting as

Mr. DERMOTT, who, when silence was obtained, said, Gentlemen, I wish to address you for the honour of the pupils at large, their future welfare, and their future character in the profession. (*Laughter, and cries of "Hear, hear."*)

The CHAIRMAN, There is at present no

proposition before the meeting. Mr. DERMOTT can speak after the next resolution has been moved.

Mr. EVANS proposed the second resolution. If they were disposed to hear the gentleman who was so many years older than himself, he (Mr. E.) would most willingly give way to him. (*Cries of "No, no, go on."*) He thought that at no time were the students called upon to be more unanimous than at present. Until lately the flagrant acts of injustice committed by the Apothecaries' Company had been kept in the background; but within the last few months, two most glaring cases had come within his own knowledge,—one was that of a most scientific man who was rejected at the Hall. Strong, however, as were his feelings on the subject, he would not abuse the Apothecaries' Company, neither, he trusted, would others at this meeting, as that would be placing in the hands of the Hall a scourge for their own backs. He was extremely sorry that the Apothecaries' Company should have put to the test, in the manner they had done, the old proverb—"Didicisse fideliter artes, emollit mores, nec sinit esse feros." (*Cheers and laughter.*) Certainly the Company was not an instance in proof of the saying. The resolution he had to propose was as follows:—

"That with a view to procure a remedy for the evils indicated in the foregoing resolution, it is expedient that this meeting take into consideration the means of redress."

Mr. PUDGETT seconded the resolution. In case, he said, any among them had been brought there by idle curiosity, or had come in opposition to the objects of the meeting, he wished that he possessed sufficient powers of eloquence to impart to them the same feeling as he himself possessed upon this subject, as he was sure they would then exert themselves to obtain their just rights, and support the dignity of the profession. (*Hear, hear.*)

Mr. DERMOTT. Mr. Chairman and gentlemen, I wish to address you before the resolution is put, and even Mr. Wakley, as a conscientious friend. (*"Hear, hear," and great laughter.*) Now, gentlemen, I think that this resolution is alluding as it were to a point of honour; and I think, and humbly submit according to the slight degree of common sense, the small degree of common sense which I possess, that there is a collusion. (*Laughter, and cries of "No, no."*) You will be so good as to hear me out, gentlemen (*cries of "Go on, go on"*)—a collusion between the pupils at large. (*Laughter.*) I come here as no spy. (*"Oh!"*) The gentlemen who know me know my heart. (*Laughter, and a cry of "Hear Mr. Dermott's demonstration of the heart."*)

The CHAIRMAN, I shall take care that

Mr. Dermott is not offended here; but I must request that Mr. Dermott will have the goodness to keep to the object for which we are assembled,—that point is, the conduct of the Examiners of the Hall.

Mr. DERMOTT. I will do so. The universal interest of the profession is involved, and it might be put to the Company of Apothecaries as a point of honour, inasmuch as their character is concerned in a professional way, that they should examine this man publicly. That is the question I wish to propose to this meeting, and if you wish to put me down on the strength of that question, for God's sake if you can conscientiously put me down, do it. ("No, no, go on, go on.") Well, then, I say their honour as professional men, their honesty in some slight degree as professional men is concerned, and therefore, upon the score of the interests of the pupils at large (*laughter*), I would wish, instead of that former resolution, that this gentleman should be examined publicly before the Apothecaries' Company, and I trust it will be seconded. I put my resolution contra to your second resolution.

No one seconding Mr. Dermott's resolution, it fell to the ground. The second resolution was then carried unanimously.

Mr. PETERS proposed the third resolution. Two or three instances had been adduced relative to the oppression manifested by the Examiners of the Hall, but many grievances were yet unstated. Numerous regulations which were in existence at the time that hundreds of students had entered on their professional studies had since been repealed, or so altered as not to bear any resemblance to their original form. (*Cries of "Shame, shame."*) It thus became impossible for students to know what to do, they could not tell what would be the amount of their studies, they did not know to what particular branches they should devote their energies, and probably at a time when they might be considered fully competent to practise, some fresh regulations were issued from the Hall, which threw twelve additional months of expense and anxiety on their shoulders. (*Shame, shame.*) No doubt the Company would say that it was all for the good of the profession, but if the majority of his fellow students thought that such a power ought not to be vested in persons who were not able to tell what was and what was not good for the profession, and were liable to abuse their privileges, this was the time for them to say so. (*Cheers.*) A most glaring instance of this abuse happened last summer, when regulations came out by which the students were obliged to incur an additional twelve months' wear and tear of mind, body, and pocket. They were now, too, especially encouraged to protect themselves, from the circumstance of the pupils of Exeter, backed by their teachers, having

swayed the Examiners at the Hall in their acts of injustice; and if twenty-five pupils at such a distance had possessed this influence, what could not the multitude do who were then present? (*Cheers.*) The resolution he had to propose was, "That in order to attain the object desired, a petition be immediately drawn up and forwarded to Parliament, praying that an equitable and just tribunal be immediately established, and that the Chairman of the meeting do sign such petition on behalf of the students present."

Mr. LANE cordially seconded the resolution.

Mr. DRAITT, of King's College, said, that the petition ought to be signed by those who wished to do so, and not by the chairman on behalf of the meeting, for the resolution might not be approved of by all, and it might be inferred that it was not approved of by all the students who were present. He moved as an amendment that the petition be signed by those gentlemen present who wished to do so, and not by the chairman on behalf of the meeting.

Mr. CHALLICE seconded the amendment.

Mr. CROOK supported the original resolution, as it was in favour of the usual method of signing petitions. Besides, one of the principal reasons was, that the Hall was not over lenient with an individual whom they considered to be opposed to them. (*Hear, hear, hear.*) If the students present signed the petition, he had not the least doubt that many of them would feel the effects of that proceeding when they went up to the Hall. The signature of the chairman would save many a man from unjust disgrace during the remainder of his life. (*Hear, hear.*) Why did not the enemy who moved the amendment declare his sentiments boldly, instead of endeavouring by a side-wind to overturn the object of the meeting? (*Cheers.*)

Mr. DRAITT again presented himself amid much opposition. They had been desired, he said, to give an impartial hearing to every speaker. As yet they had had no opportunity of showing that impartiality, but he would now afford them the opportunity. (*Hear, hear.*) He would state boldly his reason for opposing the latter part of the resolution. He did so in order that it might not be imagined either that the general body of the medical students of London were aware of this meeting, or that they were inclined to support any petition that might be founded on the resolutions which had been and might be passed. He would not attempt to retort upon the sneer that had been thrown out, but he would give his reasons for dissenting from the object of the meeting. They had met to discuss grievances, and in order to discuss them they ought to know first of all what those grievances were. One grievance had been stated, and only one,

but it had not been proved. (*Cries of "Oh, oh," and laughter.*) After what he considered to be much abuse from the chairman towards the Apothecaries' Company, a gentleman who had moved a resolution, stated that there was to be no abuse, though he considered that plenty of abuse, and gross abuse (*general hissing*), had been used. He trusted they would listen to him for a few minutes, and then he would sit down. (*A cry of "It's quite time you did so."*) They had come there to discuss grievances, and he wanted to know what the question was upon which the gentleman had been rejected. (*Repeated hisses and cries of "Off, off."*) (The chairman begged that the meeting would hear Mr. Druit.) He thought they had met to hear grievances discussed, but it appeared that they would not permit it. No grievance in his opinion had been proved, and if it had, he did not consider that they were adopting the proper means of obtaining redress. (*Groans and hisses from all parts.*)

The amendment was then put, when two hands were held up for the amendment, and the resolution was carried amidst loud acclamations.

Mr. CROOK said, he had to propose a resolution which he considered ought to have been the first, because, while it complained of the present mode of the examinations at the Hall, it also suggested a remedy. He was not prepared to go to the extent that some gentlemen had who had spoken during the evening. He thought that if they could utter a word in praise of the Hall, they ought to do so. (*Cries of "That's impossible!"*); and as impartiality was to be one of the principles of the meeting, he was sure they would listen most attentively while he endeavoured to say a word in favour of that institution. Since the passing of the Apothecaries Act in 1815, he presumed that no one would question that the profession had been much improved. (*Hear, hear.*) If that proposition was conceded he would say, don't do away with the Apothecaries' Company; modify it, reform it, but don't destroy it. In his opinion the great fault of the Company was, that the licentiates of the Hall had not the governing body under their control. If they had, the Company would never dare to inflict the acts of injustice of which they had been guilty. Why would they destroy the Company? (*A voice. "Have you passed?"*) Mr. CROOK. "Yes, I have." *The voice.* "Well, what do you think of their ability?" He (Mr. Crook) could not say much about their ability, and as to their civility, he could say even less. In moving the fourth resolution, he did not consider that he was in any way acting for the destruction of the Company, and he thought that the meeting agreed with him in considering that it ought not to be abolished. (*General cries of dissent from the last observation.*)

Some gentleman had proposed the right of appeal for a second examination to another tribunal. That would be as bad, unless the higher authority were also to be elected by the members at large. Mr. Carpue having promised to address them, he would conclude by reading the resolution, viz. :—

"That it is the opinion of this meeting that nothing will more essentially contribute to the honour and efficiency of the profession, and the public good, than that the examiners of the institution under consideration should be elected by the members at large, and that no reform can be satisfactory that does not render the governing body accountable to the governed."

Mr. BARLOW seconded the resolution.

Mr. ——— said that he thought that the proceedings of this meeting were well calculated to raise the character of the profession in the estimation of the public. It had been stated that the grievances complained of that evening had not been substantiated. He did not stand forward to discuss individual cases, but he contended that the principles on which the examination was based were bad. Before one man had the legal power of examining another upon any branch of the profession, he ought to give proofs that he himself had attained proficiency in that branch, and he would boldly assert that the members who at present composed the Court of Examiners at Apothecaries' Hall had not given proofs of proficiency in any branch of science whatsoever. (*Hear, hear, hear.*) It was not a court which was calculated to raise the character of the noblest of professions in public estimation. (*Cheers.*) Ought the doors by which students entered the profession to be opened or closed by such a body, just as they thought fit; and were the intellectual medical students of this kingdom to be placed at the tender mercy of a self-elected and irresponsible tribunal? (*Reiterated cheers.*) Even if any individual could come forward and praise the illustrious Company, —admitting such an absurdity for an instant—yet it could not be proved that the system of examinations was not deserving of the strictest reprobation, as that of a self-elected body. (*Cheers.*) It would never do justice to the public; it would always act upon its own private feelings to candidates. Mr. Druit hinted that it could not be told whether the meeting approved or not of the resolutions, but surely, if a man held up his hand by way of voting, he knew what he was doing, and they all knew what were his sentiments on the points under discussion. (*Hear, hear, hear.*) As regarded the marking of men who had come forward on the present occasion, he did hope that the Apothecaries' Company would, if the opportunity occurred, move that they were too timid, if not too base, to act in such a manner. (*Cheers.*)

Mr. CARPUE was received with cheers, and spoke as follows—Gentlemen, the individual who has the honour now to address you, has given a hundred courses of lectures on anatomy and surgery; and you may be assured that it gladdens his heart not a little to see such a body of students come forward and say—not, “Do not examine us,” but “Examine us in such a manner, that the world may see whether we merit or not the diploma.” But unfortunately, the examinations have been private, and grossly partial. Oh, I could tell tales unfolded relative to the examinations that would harrow up your very souls, but I must not do so. You have now put the matter into a train for alteration. (*Cries of “Yes, yes,” and “Public examinations.”*) Can any man, or any set of men, complain of you for this? To your own feelings how gratifying the circumstance, that when you have worked night and day to obtain the reward of study, you can advance to an honourable, and an honour-conferring examination, to receive the reward of your exertions! (*Hear, hear.*) Yet in this great country, such a reward has never yet had an existence, but the system of medical education has been loaded with difficulties without honours. Unless you pay so much, as a surgical apprentice-fee, and have an hospital or a wealthy connection, you must be a miserable apothecary, and are shut out from all those offices which your exertions and your talents ought to have opened to you. (*Hear, hear, hear.*) Gentlemen, I have, fortunately, made myself independent by professional exertions, and I now come forward to assist you to obtain the same opportunities. (*Cheers.*) Few, indeed, can hope, under the present system, to possess them. Look at the College of Surgeons. See there the bust of that great anatomist, unhappy Brookes. (*Cheers and “Question.”*) Surely you cannot wish to interrupt me, when I speak of the injustice, the bad conduct, the baseness of the College, to that first of anatomists. (*Hear, hear, hear.*) If ever man was entitled to hold a seat in the Council of that College it was Brookes, and, had he possessed it, he would have been alive now; but, gentlemen, I tell it you with tears, that that anatomist died from absolute poverty—from absolute starvation (*cries of “Shame!”*); and the best pupil of the present day might do the same, as another result of the existing system. Gentlemen, I sincerely hope that you will succeed in your present just and excellent object.

The resolution was then put to the meeting, and carried unanimously. Mr. WAKLEY was then loudly called for, and the CHAIRMAN said he understood that Mr. Wakley would speak after the next resolution was proposed.

Mr. BURR proposed, and Mr. FENNER seconded, the next resolution, viz.—“That H.

Warburton, Esq. be respectfully requested to present to the House of Commons, a petition, to be drawn up, expressive of the opinions of this meeting, and that the Members of the Parliamentary Committee of Inquiry into the state of Medical Education and Practice, be also requested to support the same in their places in the Legislative Assembly.”

Dr. — BLUNDELL said he would briefly address the meeting. He had waded through the profession like themselves, and he supposed they were now considered as worthless as he was. Suppose that some gentleman, possessing all the intelligence in their collected heads (*laughter*), went up to the Hall to be examined, and that very learned Society chose to say, “Sir, how many protoxides of mercury are there?” That would be an ignorant question. The difference between the protoxide, and the deutoxide, and the tritoxide—(*The laughter prevented us from hearing the end of the sentence.*) There might be individuals in the company not members of the profession, who had come out of curiosity, perhaps, and, therefore, when he talked about protoxide, and deutoxide, and tritoxide, he was talking Greek to them. (*Cries of “Question,” and “We don’t want a lecture on Materia Medica.”*) He was only following up Mr. Carpué’s views. A friend of his was rejected, the other day, for not being able to tell how many protoxides of mercury there were. The collected medical wisdom of England said his ignorance might lead him to kill the King’s subjects. (*Question, question.*) Yet this gentleman had an intelligent mind, and was well versed in botany, anatomy, physiology, and medicine. If the Court of Examiners—if the Court of Apothecaries would allow him (Dr. B.) to come before them, he would put every man of them down. (*Laughter.*)

Mr. WAKLEY was here called for from all parts, and received with many rounds of enthusiastic cheers. He spoke as follows:—In standing before the meeting on this occasion, I yield rather to the advice of others than to the dictates of my own judgment, although it is my duty, circumstanced as I am, and holding the sentiments which I have professed now for some years on the subject of Medical Reform, to contribute in every possible way to the advancement of your interests, which I know are identified with the best interests of the public. Gentlemen, I have indeed passed a pleasant evening on this occasion. To see you assembled to promote the great and paramount object for which I have myself been so long contending, is a source of gratification to me which I know not how to describe. There is a French saying “that those who help themselves Heaven will help.” Your prospect is then truly flattering; and let me tell you that you have to-night settled one

great question of Medical Reform in agreeing to tell the Legislature that your confidence in your information, your attainments, and your industry, is such that you care not for—nay that you invite—a public examination into your qualifications to practise medicine—that you are prepared to submit to an honest, just, and deliberate scrutiny, but that you refuse any longer to be subjected to the dishonest and unworthy practices which are played upon you by the Worshipful Company of Apothecaries of London. (*Hear, hear, hear.*) When I have urged, time out of mind, that public examinations for degrees, diplomas, and licenses, should be instituted, what has been the invariable reply of your enemies—those who, however, have at the same time professed themselves to be your ardent friends? “Oh, poor fellows!” they have said; “they cannot stand such an ordeal; their nerves would be agitated in public; they would tremble too much; they would be incapable of showing what little talent they do possess.” (*Much laughter.*) Gentlemen, this was a base calumny. You demand this fearful investigation. (*Cheers.*) And now what will your enemies say, and what will the Legislature respond in deciding on the conditions, the arrangements, and the principles of a New University? (*Hear, hear, hear.*) How will the corporators in the halls and colleges dare any longer to assert that the medical students of the metropolis are frightened at public examinations? The gentleman who proposed the fourth resolution has stated, with that kind-heartedness which is so manifest in his countenance, that he was anxious to amend but not to destroy the Apothecaries’ Company. Gentlemen, I will make no comparison between our organs of destructiveness on this occasion, but I can tell him this, that so far as the Act of 1815 is concerned, the foundation of the Company’s power, the adoption of his proposition by the Legislature, will, most assuredly destroy that Company for ever, for it upsets the very principle upon which it is founded. (*Hear, hear, hear.*) The Company would lie upon no bed of roses if public examinations were made essential to the possession of professional privileges. Only imagine the ordeal which the men in the present board of Examiners would have themselves to undergo, and the extent of ignorance they would expose. (*Great cheering.*) No, no, gentlemen. They are altogether out of place as examiners of medical students. The charter of James I. simply authorized that Company to superintend the drug-shops of London; and I say, let the Hall again occupy its old station. Let it not presume to interfere with or control the medical practitioners of England. It is utterly incapable of executing the duties of so high an office, so dignified, so exalted a station, and, therefore, let it be confined to

the exercise of its original and very useful function of examining the chemists and druggists of London, whose labours are far more profitable to them—whatever their competency or their respectability—than are those which are exercised by the medical practitioners. The chemists and druggists at present are without control; no authority is exercised over them by any company. They do just what they please behind the counter, and you are the sufferers. (*Hear, hear, hear.*) To propose what is suggested in your fourth Resolution, is not to propose a reform in the Company, but its abolition, for in effecting such a change in the Act of 1815 as would be necessary, the Apothecaries’ Company would sink to the earth. But in establishing the new University—an institution which if constructed, as it ought to be, and according to the principles which common sense inculcates, will prove of more advantage to the English nation than any institution that has been established for the last hundred and fifty years—in the new University, I say, the views expressed in the fourth Resolution may be most beneficially adopted. To that Institution they must apply, and when I reflect upon the influence which medical practitioners exercise over the minds of the community, the blessings which they confer on their fellow creatures, and the quantity of human suffering which they daily relieve,—I cannot believe that any reforming Government will be insensible to the demand which you now make. (*Great cheering.*) As has been properly said to-night, this is no question of party or of politics; it is a question of the welfare of the English nation, of health or disease, of life or death. All minor considerations should merge in the accomplishment of the great object you have in view. It is right that men should not practise without a most careful and judicious scrutiny into their qualifications; but when I reflect upon the drudgery which you have to undergo for a long series of years, upon your innumerable toils, your perplexities, your anxieties, and the hopes you cherish, I cannot conceive how any man can be so cold-blooded and so base as to make the very moment which ought to be a period of triumph and honour, the hour of degradation, misery, and disgrace. (*Loud cheers.*) Gentlemen, such meetings as these ought frequently to be held. The public know not your case, they know nothing of your anxieties, nothing of your sacrifices. Do they suppose that you possess hearts of stone and nerves of steel,—that human suffering has the effect upon your minds and feelings of hardening them to surrounding misery? If they conceive for an instant that your object in carrying on the duties of your profession is merely mercenary, they inflict on you a grievous wrong. I am satisfied that thousands of medical men

exist who are continually endeavouring to relieve their fellow men from the agonies of disease, without once supposing they can derive pecuniary profit for their skill. (*Hear, hear, hear.*) The public then ought highly to appreciate the pains and perils which you undergo in endeavouring to obtain a knowledge of that profession which is thus devoted to the wants of the community. If then your claims are now made for the aid of Parliament, and then enforced as I know they will be, no effort that may be made by designing men can frustrate the object you have in view. (*Great cheers.*) Gentlemen, on this point let me do my political enemies in the House of Commons the justice to say that I never yet saw men listen with more attention, or treat with more respect, the parties who advocate your interests in the House of Commons. (*Much cheering.*) If there be a shade of difference in this respect between the two contending parties in that assembly, I am bound by truth to say, without designing to give offence to any one, that the brightest side is not with the liberal party. (*"Hear, hear," from the King's College students.*) I know not how it happens; I cannot conceive from what cause it proceeds, but, really, during the last session, when emoluments were proposed for medical men at coroners' inquests, the opposition came from the liberal, and not from the other side of the House. Now I mention this to you because I am anxious that the little misunderstanding which exists in the minds of many persons should be removed. You know a good many members of the House. Try them yourselves: ask them what are their objections to giving to medical men their due. (*Hear, hear.*) Gentlemen, the resolution which was last proposed refers to Mr. Warburton. Your petition is to be placed in his hands. A more proper proceeding could not be adopted. The labours of Mr. Warburton in your cause are deserving of unbounded praise. (*Hear, hear.*) His assiduity is unabating, his honesty is unquestionable, his intelligence is of the highest order, and I am sure that no effort will ever be wanting on his part to give effect to any resolution which you may pass. A disaster occurred at the Houses of Parliament last year, by which, as you know, a number of medical papers were consumed; and Mr. Warburton's report has, consequently, been much delayed. The committee will by-and-by be re-appointed; and the whole of the evidence, and the report founded thereon, will be laid before the House. Your resolutions, therefore, come just in time (*loud cheers*); and I thank Mr. Ridout for what he has done on this occasion; I am most grateful to him for his labours in our cause. (*"Hear, hear, hear," and laughter.*) Why, he is the author of this meeting! It is the Court of Examiners who have advanced the work of medical reform

to-day. In thanking Mr. Ridout, do not understand me to rejoice at what has been called the degradation of the candidate. Who, however, will contend that a student can be degraded at the Hall? (*Hear, hear, hear.*) It is monstrous to conceive such a thing. Gentlemen, the rejection is no disgrace, and the passing the examination is no triumph. (*Hear, hear.*) As he cannot acquire honour in the one case, he cannot get degradation in the other. Why, you yourselves, by your proceedings to-night, have shown that you entertain not the slightest respect for that body. (*Universal cheering.*) You have resolved aright in determining that it shall no longer continue to inflict undeserved punishment on medical students. In establishing a new University, the great principle of public examinations must be conceded. They would be perfectly legal, even on the part of the Apothecaries' Company. There is not a single clause, line, word, or syllable, in the act of 1815 which prevents them from holding the examinations in public; and who has ever demanded that they should be carried on in private? Nay, I have no doubt that when that act was passed, the legislature presumed that the examinations would be carried on in public. The subject, however, was not mooted in the House of Commons; the act, in fact, was passed with scarcely any discussion. But there is another point. I say that the examination of the gentleman who was rejected was an illegal examination. He can compel the Court to examine him again, by an application to the Court of King's Bench, for the ninth section of the act requires that the examinations shall be conducted by a majority of the Court, but he was examined by one individual, consequently it was not a legal examination. There are twelve Examiners, and there must be seven to make a Court. The majority of seven, according to Cocker, is four. Now I am told that there are four tables in the room. Are the Examiners Hydras? Can they multiply their heads as occasion may require, so that a proper number of heads may be at each table to give a decision in favour of or against a student? (*Hear, hear.*) I say therefore that Mr. Smith, if he chose, could compel them to institute another examination, but I trust he will do no such thing. I hope he will rely on the challenge he has given them to examine him in public. In the presence of his professional brethren. Were such examination given to him, the paltry, miserable, manœuvring, tricky, questions that are now put to students at the Hall, would never be proposed. They are now submitted, not to ascertain the depth of the student's information, but to perplex and distress him, and to show the cunning and dexterity of the Examiner. When public examinations are conducted by men who have been elected by public

concourse, then the student will be examined first as to your knowledge of the general principles which regulate the functions and movements of the animal body, and the treatment of diseases. Having proved his competency to discuss and explain those principles, the student would be examined on the details of anatomy, physiology, chemistry, medical practice, &c., the object of the Examiners being to put those questions which are important as tests of knowledge rather than such as are perplexing, and calculated to confuse the mind of the candidate. Only imagine, if a tricky question were proposed to him, what a simultaneous and overwhelming exclamation of indignation would be ready to burst from one or two thousand tongues! (*Hear, hear, hear.*) Depend upon it this punishment would prevent another such attempt from being made. In the course of my duties as a journalist, I have often witnessed the streaming eye and the aching heart of unfairly rejected students, and no feeling of distress can be greater than the disappointment of a meritorious and deserving student, is calculated to create. I have known this happen to young men who have expended their last shilling in London,—the last farthing their relatives could devote to their education, and to the purchase of tickets and certificates. I have known the week arrive when their pockets were empty, but when they have expected that their heads were full of information to enable them to pass; and yet they have been treated with insolence and contempt before the Courts of Examiners, their hopes have been blasted, their expectations wholly falsified, and at the very moment when they hoped that triumph would crown their exertions, and that the object of their emulation was achieved, they have been sent back to linger out six or nine months more, or they have altogether abandoned the profession, and their prospects in life have been for ever blasted. (*Great cheering.*) Gentlemen, you would be undeserving of that reputation which I know ought sooner or later to be conferred upon you, if you did not use every exertion to remove from yourselves and your fellow students throughout the whole empire, the cause of so much undeserved calamity, degradation, and misery. (*Cheers.*) What have the Examiners themselves to say upon this occasion? They have nothing. They will not inform either you or the candidate on what point they refused to grant him the license to practise. He is in total ignorance upon the subject. The Examiners are too cautious to make such things known. The Examiner who rejected him does not dare to state why the student was unsuccessful. If he did, it is fifty to one but that his own ignorance would be exposed. All other students who go up for examination are in a state of uncertainty upon the subject on

which this young man was rejected. They may in reality be required to go up to the Hall with their heads crammed with false doctrines, instead of true ones, and without being prepared for this, you yourselves may share the same fate. All this perplexity will be destroyed by public examinations before competent tribunals; and it is the duty of the Legislature to act upon your declaration to-night, and to adopt your prayer. (*Hear, hear, hear.*) When your petition is presented to the House, and the extent, the respectability, the patience, and the orderly conduct of this meeting are explained to them, I am very much deceived if you will find in the House of Commons one man who will dare to assert that the prayer of your petition ought not to be granted. (*Cheers.*) But, gentlemen, the House does not meet for a fortnight, and I should be uncommonly glad if, before you break up to-night, just at the lag end of the business, you were to appoint a little deputation to wait upon the Chancellor of the Exchequer, because there is a charter now framing for a new University, and it has been the practice for the King to exercise the royal prerogative in the Privy Council Chamber. (*One of the King's College knut of students here called out "No politics," which was angrily deprecated by cries from all other parts of the room.*) It has not been the practice to make known the conditions of charters before they are actually granted, and when they are granted, it is almost too late for you to know them. I am anxious, therefore, that the Chancellor of the Exchequer should be made acquainted, officially, to-morrow, with your proceedings this evening, because it may have a most important effect in governing his mind relative to the conditions of the new University Charter. (*Cheers.*) I think the suggestion is a very useful one, for the monopolists say that the Chancellor has delegated some of his authority in the matter to other parties. I will not name those parties, but I do think that the subject is of so much national importance, that nothing should be done with regard to it except publicly. You have a right to know what is going to be done on this occasion. The whole of the community is concerned in it, and, therefore, if some one on your behalf were to communicate with the Chancellor of the Exchequer to-morrow, merely announcing to him the resolutions which you have adopted to-night, and if an interview with a deputation were requested, it might stay his hand with reference to the ~~source~~ conditions of the charter which, when once framed, may, though injurious to your interests, not be removed for a long series of years. Remember that the Apothecaries Act, with all its mischievous clause, has been in existence twenty years. I wish that some benefit had resulted from that

act, but when I balance the good against the evil, I am afraid that the last makes the former kick the beam with a vengeance. (*Hear, hear, hear.*) Whatever may have been the virtues of that body, and whatever may have been the extent of its infirmities, its days, as has been truly stated to-night, are numbered, and you are about to be emancipated from as odious a thralldom as ever existed over a body of intelligent men. (*Long protracted cheering.*)

Mr. LISTON, being loudly called for, presented himself, amidst great cheering, and said—Gentlemen, I feel highly flattered by the kind reception you have given me this evening. I came here only as a spectator of your proceedings. I am a mere tyro in medical politics, but you will find in me a staunch supporter of medical reform. The present system does not work well, and I hope that in a short time we shall have a much better one in its place. (*Great cheering.*)

The CHAIRMAN then put the resolution last proposed to the meeting, and it was carried without a dissenting voice.

Mr. CUTLER proposed the next resolution. After the eloquent manner in which they had been addressed that evening by the friends of the student, there remained little to be said on the nature of the abuses which they had assembled with a view to remedy. However, he would make a few remarks, and a few only, previous to reading the resolution. He conceived that they could not do a better thing than arrange plans for the correct guidance of their future endeavours. Every school should send its deputy to a central association,—one selected from among the rest, who was competent to take upon himself the duty of representing the interests of his fellow students, until the time arrived when the Government might provide a better scheme of medical government, and candidates for licenses to practise were fairly treated by an examining board. This change, he hoped, would not be long before it was achieved, for while they (the students) had much in their own power, they had able advocates amongst their seniors, and one amongst them who was one of the greatest ornaments of his country. (*Cheers.*) The provincial students could not yet have been made acquainted with the proceedings of the students in London, but it would be right to take into consideration at a future meeting the propriety of inviting them to participate in the association which he was about to propose they should form. The provincial students were equally interested in the work of this day. He was sure they would be proud to promote any good object that might emanate from the metropolitan students. He hoped that there would be no party bickerings among the schools, no petty bickerings, according as prejudices might sway them, but unanimity

in all directions, and that the great body of the students would unite in effecting the regeneration of the medical profession. (*Cheers.*) He begged to propose

"That for the better protection of the interests, and the mutual support of the rights, of the students in medicine generally, of this empire, a great central association be formed, which all medical students be invited to join."

Mr. WISLIN seconded the resolution.

Mr. DAVITT would not have troubled the meeting again, had it not been for this resolution. (*Cries of spoke, spoke.*) He had not spoken upon this resolution, which he conceived was founded in error. (*Cries of "Oh!"*) They were directed to choose a tribunal from among themselves, to examine themselves: how could they choose a competent tribunal? Would the public respect their decision more than they would that of the Hall? Certainly not; therefore he considered the resolution altogether irrelevant to the present meeting. (*Cries of "You're quite wrong."*)

Mr. CROOK said, that no doubt the meeting would consider him presumptuous in attempting to make any reply to some observations of Mr. Wakley, yet he begged to do so for a moment. That gentleman had been kind enough to compliment him upon his general good expression of countenance. That was very kind of him. He would conscientiously return the compliment, for if ever there was a man whose countenance portrayed universal philanthropy, Mr. Wakley was that man,—

THE CHAIRMAN. You must be good enough, Sir, to keep to the subject for which we are assembled.

Mr. CROOK. I am going to speak in reply to Mr. Wakley. Mr. Wakley condemned the fourth Resolution. (*Cries of "No, no, he supported it."* "It was carried." "There was only one dissentient.") Mr. Wakley did not support the Resolution. (*Cries of "Yes, yes, he did."* and "Chair, chair.") Mr. Crook then retired, and the Resolution was put to the meeting, when, after the show of hands had been taken, the gentlemen from King's College on the platform being dissatisfied at the smallness of the minority, it was again put to the vote, when ten hands were counted against it, and the Chairman declared it to be carried, with a few dissentients, amidst loud cheering.

Mr. PAINE called the attention of the meeting to the suggestion that a deputation should be formed of twelve gentlemen to wait on the Chancellor of the Exchequer, to present the resolutions of the evening, prior to the formation of the new University. (*Hear, hear.*) Mr. Wakley and Mr. Liston had promised to head the deputation (*cheers*); and it remained for the meeting to appoint twelve other gentlemen.

Mr. EVANS seconded the motion, and

suggested that a gentleman should attend from each school which chose to send a representative. The resolution was then carried.

Mr. SMITH proposed, and it was seconded by Mr. SPARROW,—“That the resolutions passed this evening, be published in the *Morning Chronicle*, *The Times*, *The Lancet*, and *The Medical Gazette*.”

The Chairman was then deputed, in the name of the meeting, to write to the Chancellor of the Exchequer, to know when he would receive the deputation.

The thanks of the meeting were then unanimously voted to the Chairman for his able and impartial conduct in the Chair.

Mr. MADE returned thanks for the vote, and congratulated the meeting upon the proceedings, and the unbroken steadiness of conduct which had distinguished them. They had proved that they could dispassionately discuss their wrongs, and were capable of using great moral force in redressing them. They had taught the Apothecaries' Hall a lesson that night which it had never expected to receive from the students of London. The words, “a marked man,” were in common use, when speaking of some candidates at the Hall. No more men, he believed, would be “marked” at that institution. Again returning them his most sincere thanks for the honour they had conferred upon him, he begged to say that the meeting was dissolved.

Several rounds of cheers were then given for Mr. Warburton, Mr. Wakley, Mr. Liston, and the Chairman, and three groans for Mr. Ridout, and some other examiners at Apothecaries' Hall, and the immense assembly quietly separated.

We have been informed that nearly eighteen pounds were collected at the door of the great room, from students, in sixpences, towards defraying the expenses of the meeting, the advertisements, &c., when the amount received being so ample, the remainder of the assembly entered without the necessity for contribution; and the Secretary acquaints us that a letter was forwarded on the next morning to the Chancellor of the Exchequer, requesting that the Right Hon. Gentleman would appoint a time, as suggested, for receiving the deputation.

LATE ELECTION AT THE RICHMOND HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

SIR,—An anonymous communication purporting to be “a statement of facts,” respecting the appointment of a surgeon to the *Richmond Surgical Hospital*, has appeared in your Journal of the 9th inst.

As this statement (so far as we are concerned) is devoid of the slightest foundation,

we deem it our duty to give it the most direct contradiction under the responsibility of our signatures:—

1st. We received no list of candidates from the Government, nor from any other quarters.

2nd. We never presumed individually, or as a body, to approach the Government on the subject of the appointment in question.

3rd. Our communication with the Government was limited to our giving an official answer to an official inquiry respecting the fitness of Messrs. Mc'Donnell and Adams to perform the duties of surgeons to the Richmond Hospital.

We have the honour to be, Sir,

Your obedient servants,

PHILIP CRAMPTON.

ABRAHAM COLLIER.

RICHARD CARMICHAEL.

Dublin, Jan. 12, 1836.

DR. GEORGE GREGORY has just been appointed Professor of Materia Medica, at *King's College*, Strand. Dr. GEORGE GREGORY proved on a certain occasion, before the *Westminster Medical Society*, that he was pre-eminently qualified as a professor, and the circumstance that he has been poked into one of the empty chairs of *King's College*, proves that his claims have not been forgotten. Verily this institution is in a hopeful state.

It is more than likely that this worthy gentleman would have obtained the post, had there been a dozen candidates, because he was owed something by his party, had not yet been paid, and could at no other time be paid so cheaply. However, the fact is, that Dr. GREGORY was the *only* candidate. Dr. WENDELL had previously been officially informed by Mr. MAYO, on the part of the managers of this liberal institution, that “he was not eligible to become a candidate, because he was a member of the ‘established church of Scotland;’” and we may here take the opportunity of adding that Dr. RITCHIE, one of the ablest and most scientific men in this country, was also informed some time since by the professors of *King's College*, that “if he would change ‘his religious creed, and become a member of the Church of England, he should be elected to a chair in the institution,’ but not on any other condition.”

If it by such men as these that the students of *King's College* have allowed themselves to be made tools in the opposition to their fellow students in London within these few days. Oh, shame! The inroads of party should have fallen short of that.

Respecting Dr. WENDELL, we hear that his late conduct, in treating the authorities in the institution, has been gross and becoming in every particular.

THE LANCET.

LONDON, SATURDAY, JANUARY 30, 1836.

[1835-36.]

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

ENCEPHALITIS.*

GENTLEMEN,—Encephalitis consists in inflammation of that part of the cerebro-spinal axis which is contained within the cavity of the cranium. Although within the last few years considerable progress has been made in the study of inflammation of the brain, and within that period the science has made a rapid march, thanks to the labours of MM. LALLEMAND, ROSTAN, BOUILLAUD, and others, yet we are compelled to confess, that in spite of the knowledge which we have derived from these authors, our ideas on inflammation of the nervous centres are not yet very clear or precise.

* The present Lecture supplies a deficiency which exists in Lecture IV, published in our Number for Dec. 19. In order to secure the best position for hearing the Discourses of M. Andral, the gentleman to whose care the reporting of the lectures was confided, procured from the professor a special card of designation to the lecturer's own table, within the circle of the amphitheatre. But on the occasion on which the lecture on Encephalitis was delivered, this precaution was neutralised by an unexpected influx of auditors, who, while they succeeded in gratifying their desire to place themselves close to the professor, and secure very comfortable seats, rendered the rules of decency, and so crowded the amphitheatre, that the professor, that to report verbatim was not possible. Anxiety to publish the lecture with unquestionable accuracy, subsequently prevented us from giving place, in their proper form, to the brief notes then taken, but we now place before our readers a correct report of the lecture. It forms the commencement of M. Andral's discourse on encephalitis, and may, we believe, be read with as much advantage now as in an earlier number. The affair is simply one of transposition, which no foresight or precaution could have prevented, but which every care has since been taken to render immaterial to the perfection of the course.

The difficulties that beset us in the study of disorders of the nervous system in general, are peculiarly great with respect to the brain, where inflammation of the nervous pulp is not characterized, in the same clear and decided manner, by the production of constant and unequivocal symptoms, as inflammation of other important organs, the lung, for example, or the abdominal viscera. The difficulty of appreciating the symptoms, so as to arrive at a precise knowledge of the seat of the lesion, is also increased by the circumstance that we cannot always separate easily the phenomena depending on actual inflammation of the cerebral substance, from the symptoms which accompany irritation or inflammation of the membranes. Hence a great cause of obscurity,—a result which, from the nature of the relation between the nervous pulp and its neurilemma, it is often impossible to obviate. Besides, inflammation of the substance of the brain is not a disease so common of occurrence as you might be led to imagine from the accounts of certain authors. Encephalitis, as we understand the word, simple encephalitis, uncomplicated with any other disease, is, in reality, a rare affection. You may spend several months at the hospital without having occasion to witness a case: in short, inflammation of the substance of the brain or spinal marrow cannot be considered as a frequent disease, except by those who, too readily confounding similar appearances, have described every anatomical lesion of the cranial contents

under the name of "encephalite," or who denominate as "myelitis," all acute lesions of the medulla spinalis.

Symptoms simulating Encephalitis.

To characterize inflammation of the nervous centres presiding over animal life, we must have a certain assemblage of symptoms, into whose particular history we shall presently enter in a manner calculated, as far as lies in our power, to render the subject complete. We say, an "assemblage of symptoms," for if the practitioner should found his diagnosis on one or two leading symptoms alone, delirium, or convulsions, for example, he may fall into the gravest errors. Thus we should avoid confounding with encephalitis the nervous symptoms which present themselves in the commencement or progress of an *enterite folliculeuse* (typhus fever), at the breaking out of an eruptive malady, and in the course of several other disorders. The greater number of children who have been cut off by an acute disease, present symptoms of disorder of the nervous centres, delirium, &c.; yet we find no reason for believing these nervous phenomena to be connected with encephalitis. The substance of the brain is healthy; we discover no trace whatever of inflammation within the cavity of the cranium, and are compelled to regard the accidents alluded to as the effect of sympathetic reaction.

Again, towards the termination of several chronic diseases, when the patient has been worn out by long-continued suffering, the nervous system is more or less disturbed, and we observe various cerebral symptoms, yet we are not qualified in attributing them to inflammation. This is frequently seen in cases of pulmonary consumption, where the patient becomes delirious and agitated a few days before death; yet the brain is rather less injected than in the normal state. The contents of the cranium are found in a condition of anemia rather than of hyperemia or inflammation, a circumstance which is certainly important in a therapeutic point of view. In typhus fever, whatever may be its form, no matter with what degree of intensity it may present itself, the nervous system plays an extensive part in the production of the functional derangements observable during life. There is disorder of the brain as well as disorder of the digestive tube, but we cannot affirm that inflammation necessarily accompanies or gives rise to the symptoms in either system. We may have a typhoid delirium without encephalitis, as we certainly may have a typhoid diarrhoea without inflammation of the mucous membrane of the intestinal canal.

A comparison of the functional disorders observed during life with the pathological lesions which anatomy reveals, places it beyond all doubt that the functions of the brain may be deranged, or even profoundly

modified, without any inflammation of the nervous pulp. Thus, nervous traumatic delirium, the derangement of the intellect known by the name of "delirium tremens," &c., are not symptomatic phenomena of an internal cerebral inflammation; far from it; they exist in most cases with a discoloured state of the nervous substance. Instead of yielding to, they are aggravated by sanguineous depletions, and are in many instances, as you all know, removed as it were by enchantment, under the influence of opium in elevated doses, a remedy which is fatal in inflammation of the brain.

Encephalitis, or inflammation of the contents of the cranium (meninges excepted), differs in several respects, according as different parts of the brain may be affected: it also varies according to the degree of intensity with which inflammation may exist: hence there are

Various Distinctions of the Disease.

In relation to the first head, we may subdivide it into three species. *First:* Inflammation of the cerebral hemispheres. *Second:* Inflammation of the central medullary parts, viz., the septum lucidum, fornx, and inferior part of the centrum ovale. *Third:* Inflammation of the cerebellum. Again, with respect to its intensity, encephalitis may be distinguished, like many other inflammations, into acute and chronic encephalitis. Acute encephalitis may be general; the whole mass of the nervous centres being attacked at the same time; but this extensive disease is excessively rare: it may be partial, confined to a small portion of the nervous substance; this is much more generally the case. One hemisphere of the brain may be attacked, while the other remains free from any inflammation, or only a small portion of the hemisphere may be implicated in the disease; in a word, encephalitis, like congestion, may occupy any part of the cerebral mass. We explained fully the varieties of degree and seat, when treating of cerebral hyperemia, it is unnecessary therefore to repeat details into which we have already entered.

I have distinguished inflammation of the brain into three divisions, according to the seat of the affection, viz., inflammation of the hemispheres of the cerebrum; of its central white parts; and, finally, inflammation of the cerebellum. This is a necessary distinction when we come to speak of symptoms; however, as the anatomical characters are the same, no matter what point of the nervous centres may be the seat of the disease, we shall now proceed to sketch a general view of the morbid anatomy of encephalitis.

Anatomical Characters.

These, as we have just said, are invariable, whether the inflammation may

occupy the convolutions, the deeper parts of the cerebrum, the mesocephale, or the substance of the cerebellum. The first and most remarkable character is an injection, more or less well marked, of the cerebral pulp. The gray and white substance evidently receives more blood than in the normal state; it is more red than natural, tumefied, and sensibly more firm, than in a healthy brain; these appearances are, as you see, also common to congestion. Can we distinguish, with any degree of certainty, whether this abnormal injection is in fact truly inflammatory, or dependent on a simple hyperemia of the cerebral substance? No: simple congestion cannot always be distinguished from this, the first stage of inflammation; it even passes, by insensible degrees, into the latter, and it is often quite impossible to say where the congestion ends, and the inflammation commences. This is not peculiar to the brain, although it is, perhaps, more difficult to distinguish the two lesions, of which we now speak, in the brain than in any other organ. You will find the same difficulty of separating the two conditions in thoracic affections. How often are we at a loss to decide whether a portion of lung is simply engorged and congested, or actually inflamed! The abnormal coloration, which distinguishes the first stage of cerebral inflammation, is very various in degree. Sometimes the injection is bright, and the small vessels are excessively distended, even so far as to allow here and there effusion of blood in small quantities, which we find disseminated through the inflamed mass. In other cases the injection is less striking, and when the nervous substance is sliced off, we merely observe a greater number of bleeding points than usual; in short, the colour may vary from a deep red to the most delicate rose. However the injection may vary in different cases, we never find this anatomical character alone; thus the nervous substance sometimes presents a kind of tumefaction depending on the increased afflux of blood to the part; and this turgescence may be carried to such a degree, as sensibly to augment the volume of the cerebral hemispheres: this is a circumstance well worthy of attention. The nervous pulp, submitted to the effects of an irritating cause, becomes tumefied with wonderful rapidity; and the cerebral hemispheres, too large for the inelastic osseous case in which they are contained, become pressed upon, and various accidents manifest themselves, depending more on this compression of the nervous substance than on its irritation. This is the reason why the brain constantly tends to escape from the cavity of the skull, and form a hernia externally, whenever inflammation of the nervous pulp coincides with an accident depending in the osseous part. Hence, when we remove the skull-cap, we frequently observe that the

diseased hemisphere is evidently more developed than the one on the opposite side, to which irritation has not attracted an increased quantity of fluid. The convolutions appear pressed closely against one another, packed as it were too tightly in the cranium, and the surface of the brain no longer presents the anfractuosités by which it is so characterized in a normal state. The inflamed hemisphere, tumefied in all points, and increased in volume, tends to occupy more space than it should do, encroaches upon the opposite portion of the brain, and thus produces a variety of accidents all depending on mechanical pressure.

In the early state of inflammation, the cerebral substance has probably already acquired a tendency to become disorganized; however, the only lesions we observe, are the two just mentioned, injection of the nervous pulp, with tumefaction, and a slight increase of the normal consistency; but when the inflammation has lasted for a certain time, we observe characters of a less equivocal nature. The inflamed nervous tissue undergoes a change of consistency. It has lost much of its resistance, is soft, and gives way under the least pressure. This is a general law of pathological anatomy, affecting all organs as well as the brain; hence ramollissement, or softening of the brain, may be an effect of inflammation, and when it is the consequence of acute inflammatory action, the ramollissement is always accompanied with more or less injection of the cerebral substance. In chronic inflammation of the nervous pulp, we also have more or less ramollissement, but instead of congestion, or increased vascularity, we generally find an infiltration of purulent matter which has broken down, and, as it were, dissolved the cerebral substance. Acute inflammation of the brain may also terminate by suppuration; indeed, we may say generally, that every inflamed tissue has a tendency to generate pus, and that the brain is not exempt from the general law. Hence the presence of a purulent fluid is one of the best proofs we can have that inflammation has actually existed in the nervous tissue, abstraction being made of certain rare cases where its presence in the brain results from what has been called "abscess by metastasis."

The pus exists at first in the form of infiltration; the cerebral substance is then intermixed with a quantity of purulent secretion, which every day renders more and more friable, soft, and at length almost liquid. In proportion as the disease advances (if the patient happens to survive the first stage), the mollicules of purulent fluid become united into one mass, and form a true abscess; however, encysted abscess results much more frequently from chronic than from acute inflammation of the cerebral substance. Sometimes the le-

sion is confined to a single point of the brain, and we find only one abscess; at other times, various portions of the hemispheres contain circumscribed collections of pus. Ulceration is another form by which inflammation of the different organs may terminate. Do we observe this in the brain? Yes; the observations of SCOTTES and ASHCROBIE leave no doubt but that inflammation of the nervous pulp may give rise to ulceration of the brain; but the disease is one extremely rare.

The existence of gangrene is by no means so well established. It seems, on the contrary, doubtful that this termination of inflammation has ever been observed in the brain, although cases have been reported in the "Memoirs" of the old Academy of Surgery, and M. LALLEMAND has described one in his excellent treatise on "Diseases of the Brain." But the lesions we have now mentioned, are not the only ones which may present themselves in connection with inflammation of the cerebral substance. In a great number of cases the membranes become engaged in the disease, and are inflamed in the same way as the pleurae so often inflame when the pulmonary tissue is attacked by pneumonia. It is this affection of the meninges which produces the various morbid effusions of pus, serum, or a sanguineous fluid, that we frequently find between the membranes, or in the ventricular cavities, and which give rise to important modifications in the symptoms of this disease.

Having thus briefly pointed out the leading anatomical characters of encephalitis, let us turn to a consideration of the

Causes which may produce Encephalitis.

These are often the same as the causes of congestion, for the one may pass rapidly into the other; however, there are certain influences that act more specially in the production of encephalitis. In the first rank, we must place external violence applied to the region of the head,—an order of causes, be it remarked, that plays but an insignificant part in the production of cerebral congestion. Thus blows, falls, &c., in a word, any severe injury of the head, may give rise to the development of inflammation within the cavity of the cranium. It is not necessary that the external violence be applied immediately to the head: in some cases a severe fall, even when the individual has alighted on his feet, is sufficient to produce a commotion of the whole body, to such an extent, that the brain suffers a kind of concussion, which at first seems of little consequence, but sooner or later is followed by true inflammation of the cerebral substance. Wounds of the head may be accompanied or not with a breach of continuity. In the former case, the solution of continuity affects the bones of the cranium,

or merely the soft parts which cover the osseous parietes, and it is by no means rare to see encephalitis developed in consequence of a simple wound of the hairy scalp. There are other cases where the bones, examined externally, appear perfectly sound and intact, but the internal table of the cranium is fractured, and the periosteum more or less injured, and inflammation extends from the membranous lining of the skull to the substance of the brain.

Sometimes encephalitis is produced by the action of foreign bodies, either blunt or pointed, by projectiles, &c., which are lodged in the nervous pulp. A projectile, by its rapid passage through the cerebral substance, may determine inflammation, without remaining in the brain. At other times the foreign body remains there, and the nervous pulp immediately surrounding it, irritated by its presence, takes on an inflammatory action. However, these different bodies are far from producing in all cases an immediate effect. It is not rare to see them remain for a certain length of time in the brain, before they give rise to any inflammatory symptoms. Thus, in some cases a musket-ball has remained several months in the midst of the cerebral substance without producing any accident whatever. At a later period, well-marked symptoms of encephalitis manifest themselves, death ensues, and on examining the brain, we find the projectile surrounded by an abscess, the effect of inflammation.

We may discover the cause of encephalitis in certain chronic affections of the brain itself. Thus in some cases an apoplectic cell becomes a cause of inflammation, acting on the same principle as a foreign body, and exciting irritation, or true inflammation, in the surrounding nervous pulp. Various accidental productions have a similar influence, and should be ranged under the same category,—cancerous tumours, for example, scrofulous tubercles, especially in children who are at the same time affected with tubercular disease in the other great cavities; inflammation becomes developed around those tubercles; in many cases, indeed, it is chronic, and gives rise to few well-marked symptoms, but in others the inflammation is positive, acute, and terminates the patient's life, for death here cannot be attributed to the presence of tubercular masses in the centre of the nervous system, for these masses existed perhaps for years, without producing any grave accidents. It is to inflammation that we most attribute the fatal result, and, accordingly, we find a greater or less portion of the nervous pulp round the tubercle, injected, softened, and infiltrated with the pus.

Amongst other causes of encephalitis, we must not forget to mention acute or chronic lesions of the membranes enveloping the brain; thus, for example, tubercles are fre-

quently deposited in the substance of the pia mater; as they become developed, they penetrate into the substance of the brain, irritate the convolutions, and by their presence determine inflammatory action, exactly in the same way as any other foreign body in the brain.

We must also reckon amongst the causes of encephalitis, certain affections of the bones of the skull, as caries, exostosis, &c.; and amongst the bones commonly diseased, we may mention the petrous portion of the temporal bone as one most frequently affected with caries; hence the reason why children subject to purulent discharges from the internal ear, are so often attacked, in the end, with inflammation of the brain.

Gentlemen, you all know that the nervous expansions distributed to our several organs of sense, communicate directly with different masses of the cerebral substance; hence it is not irrational to expect that irritation or inflammation of the sentient extremity of the nerve should produce a corresponding lesion of the central organ; this is fully confirmed by experience. Thus, with respect to the causes furnished by lesions of the organs of sense, we have to point out,—for the eyes, ophthalmia, especially the internal ones, as a violent iritis &c.; for the ear, inflammation of the labyrinth and internal parts; even inflammation of the middle chamber is not without some influence on the production of cerebral inflammation; for the organ of smelling, inflammation of the nasal fossæ, particularly when it extends upwards to the frontal sinuses; it is not an uncommon thing to see an intense and mortal inflammation of the brain develop itself after the extraction of a benign or cancerous polypus of the nasal fossæ. For the skin, inflammation of the integuments of the face, of the scalp, the different forms of erysipelas which so frequently attack these parts, may determine inflammation of the brain. However, you are not always to conclude that if a patient labouring under erysipelas of the face be seized with agitation and delirium, he must of necessity have inflammation of the brain. This delirium is, certainly, in many cases, connected with a disease of innervation, independent of inflammatory action, and is merely a sympathetic phenomenon; however, in the uncertainty which reigns, it will perhaps always be more prudent to act as if encephalitis really did exist; antiphlogistic measures cannot here produce any bad result, while their neglect may give rise to fatal consequences.

Lesions of the great nervous trunks are sometimes a cause of encephalitis. M. BOVILLAUD mentions a case of this kind; a strong ligature had been applied round the brachial plexus; this determined an excessive pain in the part, which ascended along the trajectory of the cervical plexus, and at length

terminated in the symptoms of cerebral inflammation. There is no organ of the body whose inflammation may not occasionally become an exciting cause of encephalitis, so intimately are the nervous centres connected with all normal phenomena of the living body, and so readily are they influenced by every derangement of structure or function in each part of our system. However, we must again warn you against the danger of generalizing this proposition too extensively,—against the error of believing that every derangement of the nervous centres which manifests itself during the course of acute or chronic inflammation, depends upon actual inflammation of the brain itself.

The act of dentition in children is sometimes an exciting cause of encephalitis; irritation is propagated from the nervous pulp of the tooth to the central organ; however, we may remark, that congestion is more frequently the result produced by difficult dentition than true inflammation of the cerebral substance. Finally, in relating a history of the causes of encephalitis, let us observe that it may originate in over-action of the brain, the organ of intelligence; thus we have many examples on record, where this disease has been developed under the influence of excessive intellectual labour, of violent passion, and acute moral affections.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

ON A CASE OF

ASCITES AND ANASARCA, WITH DISEASE OF THE LIVER AND HEART.

DELIVERED IN THE SESSION OF 1836.

BY DR. ROOTS.

MARY ANN VAN HAGEN, aged 43, was admitted on the 9th of July last. She states that twenty-seven years ago she had a severe attack of rheumatism, and well recollects at that time having suffered pain in the region of the heart, ever since which she has had a feeling of great oppression about the end of the xiphoid cartilages, and has suffered dyspnoea, upon exertion, from that time. She has felt at times acute pain in both hypochondria, extending to the scapula, and she has several times had jaundice. Three years before she came into the hospital, she states that her belly began to enlarge, and her legs to swell, but that these symptoms disappeared in about a month, without resorting to medical aid. The cata-

menia ceased when she was 40 years of age, and have not since returned. From that time, two years and five months before she came into the hospital, she ceased to be dropsical for seven months. Her belly then (two years and five months ago) began to enlarge, and in six weeks became as big as it was at the time of her admission here. The legs too became very oedematous very quickly after the belly began to enlarge, and they so continued from that period up to the time of her admission, when the report of her state was as follows:—The legs are very much swollen, and pit on pressure. Some of the veins are varicose; the abdomen is very much distended, and tense, and the parietes are oedematous; fluctuation is, at the same time, very distinct throughout the whole of the abdomen, and there is also some tenderness on pressure. Her countenance is pallid and anxious, her lip rather livid, the tunica conjunctiva of the eye tinged with bile, her tongue slightly coated with a white fur, posteriorly and in the centre, and but slightly red at the tip and edges. She complains of considerable thirst, and has some nausea, and occasional vomiting. Her bowels, she states, are open. According to her account she passes two or three motions of a natural appearance daily; urine scanty and slightly albuminous. Her respiration is laboured, and thirty in a minute, accompanied by some cough. She also has some expectoration of thick mucus; her pulse 88, rather small, easily compressed, irregular, and intermittent. On applying the stethoscope to her chest, mucous and sibilant rattle were distinctly heard over the different sides of the chest, on either of the superior portions, whilst the respiration was indistinct, and the resonance very dull on percussion at the lower part of both sides. Upon examining the heart, that organ was found to beat over rather a larger space than natural, and there was also some heaving and a dwelling of the organ against the parietes at each systole of the ventricles. The natural sound of the heart was deadened, and the state of the pulse, as you might expect, was irregular, and it was occasionally intermittent. There was, at the same time, a loud bellows sound distinctly heard at each systole. At first this bellows sound,—which, I confess, was not, perhaps, examined with sufficient accuracy in the first instance, or perhaps it was lost in the sibilous state of the bronchial tubes,—at first it was thought to be only single, but very shortly afterwards it was discovered that the bellows sound was double.

For the first six days after her admission into the hospital she was placed upon milk diet, and the effect of diuretics was tried. These diuretics consisted of digitalis, squills, acetate of potash, the decoction of taraxacum, with some spirit of nitric ether occasionally,

and, at the same time, an occasional purgative of compound powder of jalap was given. At the end of a week no decrease of the symptoms had taken place, and as I was quite sure that such an immense body of fluid was not likely to be absorbed, the kidneys remaining still indolent, I considered it right to direct the operation of paracentesis to be performed. Accordingly she was tapped on the 15th of July, and twenty-five pints of a yellowish serous fluid were drawn off. It was after the drawing off of this fluid that the double bellows sound became considerably more distinct, perhaps, than it was before. Apparently no peritoneal inflammation followed the operation, but we were enabled to ascertain, as soon as the operation had been performed, that the liver was considerably enlarged. There was reason before to believe that the liver was diseased, because, upon percussion over the region where you might imagine it would project if enlarged, there was throughout so much duller a sound on percussion than natural, that I did not hesitate immediately upon her being taken into the hospital to write upon her ticket—"ascites et anasarca, morbus hepatitis, et morbus cordis."

After the tapping, I thought it right to try mercury in conjunction with some diuretic. I therefore ordered her three grains of blue pill, one grain of powdered squill, and half a grain of digitalis, to be taken three times a day; and she was also directed to resume the nitrate of potash, the spirit of nitric ether, and the decoction of taraxacum. Under this treatment, for the first ten or twelve days, there appeared to be some improvement; the mouth became sore, the kidneys secreted more urine, the legs were much less swollen, and the breathing was freer. In conjunction with the above plan of treatment, diminishing the quantity of mercury, and merely just sustaining its influence, the iodine ointment was directed to be rubbed in over the abdomen, in the proportion of a drachm of iodine to an ounce of lard, night and morning, a drachm of such compound at each friction. This, however, produced much irritation of the skin, and distressed her considerably, it was therefore omitted, and she was directed to rub in instead the ung. potass. hydriod. She went on pretty much in the same way, I should say of improvement, from after the tapping had taken place, to about the end of the first week in August, when the belly again began rapidly to fill, and I wished to try small quantities of elaterium. I accordingly directed the twelfth of a grain of elaterium to be given, with a drachm of spirit. nit. ether. every six hours, but this dose proved too active, producing great pain in the abdomen, purging her very violently, and exhausting her powers too much. It was immediately reduced to the twenty-fourth of a grain, and even in this diminished

quantity it acted too violently. It was then lessened to the thirtieth of a grain, and even that acted more on the bowels than she could bear, and ultimately it was reduced to the fortieth of a grain, still in combination with the nit. ether, given every six hours. It then acted mildly on the bowels, but no increase of urine followed its use. Some dandelion was next given, in conjunction with the fortieth of a grain of claterrum every six hours, a pint of the decoction of taraxacum being directed to be taken daily. However, by the end of August, she was as large as before, although her general health seemed somewhat better than when she was admitted.

On the 3rd of September she had become so large, and suffered so much inconvenience, that it was again determined to perform the operation of paracentesis, and Mr. SOUTH, who operated on the previous occasion, operated also now, but only three pints of a somewhat ropy fluid were withdrawn, and there appeared to be at last, after the flow had ceased, some substance pressing against, and entirely closing the orifice of the canula, which was withdrawn, an elastic hollow bougie being passed in instead, but with no better success. A small quantity of blood escaped from the wound.

Now, after this second tapping, freely applied, peritonitis supervened, and was met by the ordinary treatment,—leeches, so long as there was excessive tenderness over the abdomen, and calomel and opium, given until the mouth was again sore. When the inflammatory action had subsided, palliative treatment merely was again had recourse to, and she returned to the use of digitalis, nit. ether, and the taraxacum. Still, however, there was, from time to time, pain in the abdomen, which rendered it necessary, when the mercury was left off, to recur to leeches,—even so late as the 2nd of October, soon after which time she became gradually worse, the dropsical symptoms rather increased, the dyspnoea became more violent, attended with excessive palpitation, the pulse excessively feeble, the extremities cold, and the general debility so great that it was absolutely necessary to resort to stimulants of almost every description,—wine, brandy, ether, porter, ammonia; and as there appeared to be periodical spasmodic attacks of dyspnoea, Mr. STONE, or Mr. WHITFIELD, prescribed some ethereal tincture of lobelia inflata, which considerably relieved her, and this she continued to take up to the time of her death, in somewhat increased doses, so that I think at last she took as much as 16 or 18 minims of the tincture three or four times in the twenty-four hours, in conjunction with, perhaps, a drachm to each dose, of the *spt. eth. sulph. comp.* This treatment produced only very partial and occasional relief, and she died on the

15th of November, somewhat more than three months from the time of her admission.

Now with respect to the *diagnosis*. There was no doubt whatever that general dropsy existed, with effusion into the peritoneal cavity, and an anasarca state of the extremities and trunk. Her face was occasionally swollen, the lip somewhat livid, the tunica conjunctiva suffused with bile. The dulness on percussion over the region of the liver, indicated disease of that organ,—its enlargement after the tapping proved this to be the fact. The occasional pain in the abdomen evidenced that chronic peritonitis had existed. The mucous, sibilant, and sonorous sounds in the chest, showed chronic inflammation of the bronchial tubes. The entire absence of clear respiratory murmur at the lower part of the chest, and the dulness on percussion on either side, indicated effusion. The stethoscope made the disease of the heart equally clear; I was quite sure that the left ventricle, and, indeed, I believed that the whole heart was enlarged, for it beat over a greater space than usual, as proved by its prolonged impingement against the parietes of the chest. The parietes of the heart and the left ventricle were shown to be increased, by the deadened sound of the heart. I believed disease of the valves to exist, in consequence of the bellows sound. I remember remarking, before hearing the double bellows sound, to some gentlemen present, that, in consequence of the intermittent pulse, I believed the mitral valve was the seat, more especially, of the valvular disease. Indeed, according to my own experience, whenever there is sufficient disease of the mitral valve to prevent it from thoroughly closing the orifice, you have more or less intermission of the pulse, which I do not find to be necessarily the case where there is merely disease of the aortic valves. When I heard the double bellows sound, it did not at all alter my opinion with regard to the disease being seated in the mitral valve; on the contrary, it seemed rather to be strengthened, for I conceived that some impediment existed to the flow of blood from the auricle which gave the first sound, and that when the ventricle contracted, a portion of the blood regurgitated into the auricle, and thence probably arose the second sound.

With respect to the *prognosis*. It was quite clear, from the state of the heart, and the presumed state of the liver,—a state which had existed more or less for three years, and especially for two years and five months,—that recovery was not to be expected. One could only attempt to relieve her to some extent, and for a time we succeeded. But now comes a curious point, which renders this a most interesting case as regards the *diagnosis*, because such a thing is as likely to occur in private as in public practice, where it would excite a good deal of observation,

and perhaps some anæmisation. I was quite certain,—the fluctuation was so evident,—upon first examining the patient, that very considerable effusion existed in the peritoneal cavity,—that there was ascites. At the first tapping twenty-five pints of fluid were withdrawn, and when she again became nearly as large as before, and was tapped a second time, only three pints came away. And why not more? Why, because some of the fluid must have been contained in a cyst. But that would seem to contradict my diagnosis. Was I wrong? Had I mistaken ovarian dropsy for dropsy into the peritoneal cavity? I was quite sure that I had not committed this error, though there might be an ovarian cyst containing fluid, as well as fluid in the peritoneal cavity.

The *post-mortem examination* I think solved the difficulty. Long-standing slight adhesions existed at the upper portions of each lung. The right side of the chest contained about two pints of fluid, the left, about a pint, containing no flocculi, and not at all tenacious. The lungs crepitated in almost every part, but they were very considerably congested, almost throughout, but in the very centre of the most congested parts there were small portions of the lung which were perfectly natural. The bronchial membrane presented chronic inflammation, but no mucus. The whole of the heart was enlarged; the serous surfaces of the pericardium were perfectly adherent, and both auricles were found considerably dilated. The right ventricle was of its natural size, the cavity of the left was somewhat diminished, and its walls were considerably hypertrophied. This exactly corresponded with the state of her pulse. There was none of that violent hammering stroke which would have attended a dilatation of the ventricle equal to the hypertrophied condition of its walls. The lining membrane of the left auricle was opaque and whitish, throughout almost the whole extent, excepting a portion at its posterior part of about the size of half-a-crown, which was redder than natural, and upon which there were small patches of abrasion or ulceration. The greater portion of the lining membrane of the left ventricle was also opaque, and whitish, more especially near the aortic valves. The tricuspid valve was not changed. The left auricular opening, when viewed from the auricle, resembled a small semilunar chink, rendering the action of the valve imperfect, and this opening was but just large enough to admit the point of the little-finger, which then felt an osseous or calcareous deposit. The other portions of the mitral valve were indurated, and converted into almost cartilaginous substances. The aortic valves were thickened and uneven, but still were capable of effectually performing their functions,

and in the lining membrane of the aorta there appeared to be several depositions of atheromatous matter in small patches.

Immediately upon opening the abdomen, a considerable portion of serous fluid escaped. There was fluid also in the peritoneal cavity. The liver, the stomach, and the omentum, were adherent to the abdominal and costal parietes, and were attached, partly to the upper arch of the colon, and partly to some of the superior convolutions of the small intestines. Now there also adhered slightly to the abdominal parietes, and the under portion of the arch of the colon, a dense, smooth, pellucid membrane, about three times as thick as ordinary serous membrane, which, passing in front of the small intestines, appeared to be attached to the brim of the pelvis and pubis, extending laterally on each side of the line, forming a sac, or pouch, filled with serum. On a more minute examination, Dr. BARKER found that this false membrane passed over the bladder and uterus, between it and the rectum, and was then reflected upwards, posteriorly, and, passing over the lower portion of mesentery, joined the upper portion of the membrane, where it was attached to the colon. Much of this was capable of demonstration, but it could not be completely traced to the arch of the colon. The convolutions of the small intestines adhered slightly, forming numerous small sacs, filled with fluid. The serous membrane was white, and so thickened, in many places, as to resemble cartilage. The liver, which was much enlarged when cut into, was of a brownish-red, mottled with spots, here and there, of a yellowish brown, and very much indurated, but it did not break down on pressure. The gall-bladder was very small, but contained bile. The spleen was somewhat enlarged; its peritoneal coat was quite as much thickened as, or perhaps more than, that of the liver, and granulated, and, when cut into, the spleen was somewhat darker, and much firmer, than natural. The kidneys I did not think presented any evidence of disease, although from first to last the urine was more or less albuminous. The ovaries were somewhat enlarged.

The liver [*presenting it*] is considerably enlarged, and exhibits that mottled and hypertrophied condition which is frequently observed in intemperate people. This woman had drunk much. Its peritoneal surface is exceedingly thickened; the result of chronic inflammation, and so hard, that the point of my finger will not break through its surface unless I use my nail. You may expect, that with such a liver some of the fluid would be absorbed into the system, and thus account for the yellowness of the conjunctiva.

I said that the pericardium was universally adherent. I have always told you that I am not ashamed to confess my own ignorance

openly, and now I am about to confess that I know of no symptom, general or local, by which you can positively say that total adhesion of the pericardium has taken place. If you place your little-finger in the opening of the valve from the left auricle, you will feel the bony or calcareous deposition which I mentioned, and, viewing the valve from the ventricle, you will see it is so contracted ~~there~~ as scarcely to admit of the point of the finger, though it can be passed farther in that direction than from above. There is a sort of triangular or semilunar pouch, which, from the thickening of the valve, renders it impossible for the valve to close perfectly. What has been the cause of this? Why it is the result of inflammation of the pericardium most probably following the attack which she had two and a half years ago, as she well recollected having suffered pain in the region of the heart at that time, and ever since has experienced great uneasiness and a sense of depression at the xiphoid cartilage, with dyspnoea. She then had pericarditis, which of course ended in adhesion, and hypertrophy of the left ventricle; at the same time there was, no doubt, as most frequently is the case in acute pericarditis, inflammation of the internal lining of the heart. With such a state of the heart and valves, it can be no matter for surprise that the patient was the subject of bronchitis, effusion into the chest, and general dropsy. These are only the necessary consequences of such an impeded circulation.

The double bellows sound was, I believe dependent entirely upon the condition of the mitral valve. The aortic valves had not I think, any connection with it. There must have been two impediments to the uninterrupted flow of blood from the auricle into the ventricle, — the very narrow opening, and those projecting osseous or calcareous deposits just within; either cause being quite sufficient, in my mind, to produce the first bellows sound. Then the valve being unequal to close the aperture entirely, as soon as the ventricle had received the blood, and attempted to expel it into the aorta, a portion, it is true, would go into the aorta, but a portion would necessarily regurgitate into the auricle, whence, I believe, originated the second bellows sound.

With respect then to the reason why the fluid was not freely evacuated from the abdomen on the second tapping, I can only account for it this way. Mr. Sourn tells me that the two openings were perfectly parallel; exactly at the same height, but that he discovered afterwards that he had not in the first operation made his opening in the linea alba, but a little to the left side of it; in that case the whole, or nearly as much fluid as is ever drawn off by tapping, was evacuated. In the second instance he did tap in the linea alba, but only three pints of fluid substance came away. Some-

thing was felt pressing against the canula. Now it would almost seem as though this was the result of inflammation, but it is quite certain, from the size of the membrane which I have described, and from its density, that that membrane was not the result of inflammation between the two tapplings. In the first tapping it is probable that there was a larger quantity of fluid than in the second. If the sac existed in the first instance (at the first tapping), and it was a perfect *cist de sac*, why did so much more fluid come away on that occasion? Why there must have been a less quantity effused into the abdomen at the second tapping, and perhaps some alteration in the position allowed the small intestines to press a portion of the sac against the orifice of the canula, and so prevented more fluid from coming away; for the moment the knife was plunged into the peritoneal cavity at the post-mortem examination, a large quantity of fluid escaped. I can only suppose that the pouch was not perfect, but had a communication with the general peritoneal cavity, and that in the first operation the part in which the opening was made, favoured the discharge of all the fluid. Then some circumstances occurred by which the position of the sac was changed; perhaps the bowel fell down a little, and caused pressure against the canula. As two or three pints were drawn off, a portion of the cyst would collapse, and might be driven against the orifice, and when the hollow bougie was passed, the same result may have taken place. It is quite clear that this sac must have existed at the first tapping, and that a regular organized membrane of such immense thickness could not have been formed between the two tapplings. The circumstance reflects not in the slightest degree upon the operator. The same thing would have happened to any body. In point of fact, if it reflected upon any one, it was upon me, for my diagnosis, because I had asserted that she was suffering under ascites, that is, I felt confident that the fluid was contained in the general peritoneal cavity. The result of the first operation showed that I was right, but the second proved the existence of a cyst, as well; therefore, I was both right and wrong, — provided the cyst did really exist prior to the first operation, — did exist, I mean, as a perfect cyst, or a *cist de sac*, — without any communication with the rest of the peritoneal cavity.

ON THE
MORTALITY OF INFANTS IN
ENGLAND.

By T. R. EDMONDS, Esq., B.A., of Trinity
College, Cambridge.

THE very great diminution of the mortality of infants in England is one of the most remarkable phenomena of modern times. The existence of this diminution is established upon principles universally acknowledged as true by all ancient and modern authorities on the subject of human mortality. It is, however, highly desirable that an extraordinary fact of this nature should be confirmed by a different, though not a more correct, method of investigation.

Public opinion is at present divided between two tables of mortality, the "Northampton" and the "Carlisle." The public appears to have adopted these tables as true, and to have believed them applicable to the English population in general, after their respective authors had ceased to believe so themselves. According to the Northampton Table, out of 100 born, 46.4 die before they complete their fifth year; and according to the same table, out of 100 constantly living under the age of five years, 14.2 die annually. According to the Carlisle Table, thirty-two die under five years out of one hundred born, and 8.2 die annually for every hundred living under the age of five years. In all England and Wales, during the eighteen years 1813-30, there died of females only nineteen under the age of five years out of one hundred born, and 4.6 annually out of one hundred constantly living under the age of five years.

If the number of the dying at annual intervals, under the age of five years, be known (as is the case in England), the law of mortality at this portion of age may be determined equally well in two ways, either by observing the number of births, or by observing the number of the living under the age of five years. If the relation of the dying to the living be given, the relation of the dying to the births is also given, and reversely. The English returns supply us with both these relations, which reciprocally confirm one another. I have already stated for each county of England the number of deaths under the age of five years, which occur annually for every 100 constantly living under the age of five years. I have now to exhibit the number which die before they complete their fifth year out of every hundred born.

In the English population returns are stated the number born in each country during the eighteen years 1813-30, and also

the number dying under the age of five years during the same time. If there were no deficiencies in the registered births and deaths, the number dying under five years out of 100 born would result immediately from dividing the latter by the former number (neglecting a small correction, not exceeding two per cent., due to the births having been progressively increasing). The result thus obtained will be correct, even if the deficiencies are very considerable, provided that the proportional deficiencies in the births and in the deaths are the same. If the proportional deficiencies are not the same, the apparent may be reduced to the true result by means of a small correction, respecting the amount of which there is room for very little difference of opinion. There are only two estimates before the public of the deficiencies in the registered births and deaths, each of which points to the same correction of any quotient obtained by dividing the registered deaths by the registered births. According to Mr. Rickman, the registered deaths are to be increased nine per cent., and the registered births twenty-three per cent., in order to obtain the true numbers. According to my estimate, the increase is fourteen and twenty-seven per cent. respectively. The ages of four per cent. of the total registered deaths are not specified; the true number of the deaths, under the age of five years, are also to be increased two per cent., on account of the births having been progressively increasing. According to Mr. Rickman's estimate, then, it may be said that the deaths specified as occurring under the age of five years are to be increased $4 + 9 + 2 = 15$ per cent. According to my estimate, the increase is $4 + 14 + 2 = 20$ per cent.

In England and Wales, during the eighteen years 1813-30, the registered births of females amounted to 3,129,368, and the deaths specified, as occurring under the age of five years, amounted to 622,903. If the registry of the births and deaths had been complete, or if they had been defective in an equal degree, we should have 19.9 (the quotient of the above numbers) to represent the deaths under five years out of one hundred born. But, according to Mr. Rickman, the births are to be increased twenty-three per cent., and the deaths fifteen per cent.; the quotient of the corrected numbers will then be 18.6. According to my estimate, on increasing the births twenty-seven, and the specified deaths twenty per cent., the quotient will become 18.8. These corrected quotients approach so near to each other, that they may be regarded as identical; and it may be assumed as a fact, in which all writers will agree, that the apparent results may be reduced to the true by diminishing them five per cent. In the following table, I have thought it preferable

to state the apparent and not the corrected numbers for each county. The necessary correction will not be exactly the same for every county; and a diminution of five per cent may be deemed superfluous in a case where the apparent results are already thirty per cent lower than any other results with which they can be compared.

TABLE showing the Counties of England arranged according to the Mortality under the Age of Five Years out of 100 Born; also showing the Proportion of the total Population of each County employed in Agriculture in 1821.

COUNTIES.	Dying under 5 years out of 100 born.		Females dying annually out of 100 living under 5 years.	Agricultural Population percent. in 1821.	COUNTIES.	Dying under 5 years out of 100 born.		Females dying annually out of 100 living under 5 yrs.	Proportion of Agricultural Population in 1821.

* The numbers in the first and second columns are to be diminished 5 per cent, to obtain the true numbers.

For the sake of comparing the results from the two methods of investigation, I have stated, in the third column of the above table, the number of females dying annually in each county under the age of five years, out of 100 constantly living under the age of five years; this column is merely a reprint of the seventh column of the table which I have given at page 409 of No. 641 of THE LANCET. The numbers in this column are subject to a small error consequent on its having been assumed that the living under the age of five years had increased uniformly during the eighteen years over which the observation extends—an assumption not accurately true, although never leading to any material error. The new results stated in the first and second columns, not being subject to this source of error, are more to be relied upon for classifying the counties of England, according to the mortality under the age of five years.

It will be seen, on inspection, that the two methods of investigation lead very nearly to the same results, each number in the second column being generally equal to the number in the third column, multiplied by 4.3, which is the proportion existing according to a table of mortality, founded upon either mode of viewing the subject. Wales and Monmouth are the only apparent exceptions, in which districts the registration has always been acknowledged as defective in the highest degree. I have also added a fourth column, indicating the number of families employed in agriculture out of every 100 families existing in 1821. In any given locality, the mortality of agriculturists is considerably less than the mortality of the rest of the population; and it is impossible to obtain any correct idea of the relative healthfulness of different localities, without a knowledge of the proportion employed as agriculturists, and suffering the minimum

mortality. The recent observation of the population of Belgium may be cited as an illustration of this principle. This population has been divided into two parts, one-fourth part inhabiting towns, the remaining three-fourths belonging to rural parishes. The mortality of these two sections differed to the amount of thirty per cent.

The *London Bills of Mortality*, for the 100 years ending with 1829, supply one of the best proofs of the diminished mortality of infants. Taking five successive periods of twenty years each, the rate of diminution has proceeded with extreme regularity. In the twenty years, 1730-49, out of 100 born 74.5 died under the age of five years. During the twenty years 1810-29, only 31.8 died out of the same number. The correctness of these numbers rests upon the assumption, that the registered births and

deaths have always been deficient in an equal degree. That such has been nearly the case for the last twenty years, is rendered nearly certain by the coincidence of results thus obtained with results obtained on different principles, and there appears no reason to suspect that this has not been the case throughout the entire period of 100 years. The *London bills of mortality*, for the single years of the century, have been published in a statistical work of Mr. Marshall. They have not before been published in the present form for so extensive a period. The almost exact coincidence of the numbers dying at ages greater than sixty years, during the former and during the latter half of the century, confirms the conclusions, deduced from other grounds, that the mortality in London above the age of sixty years has suffered no diminution.

TABLE showing the Ages of the Dying according to the "*London Bills of Mortality*" for 100 Years, in five periods of 20 Years each: also showing the Number Dying under five Years out of 100 born.

The method of observing facts in human mortality, is founded upon principles so obvious, and of such extreme simplicity, and yet the ignorance of these principles is so universal, that I may be excused for now offering a few general remarks on the subject. The knowledge of these principles appears to be exclusively confined to those professionally engaged in the study of the laws of human mortality; the simple principles which form the foundation of every professional work on the subject, appear to have produced no impression on the minds of mathematicians in general, or on the minds of the public. For several years past the government press of England has been widely diffusing erroneous principles and unfounded results. The

few persons who through their knowledge and reputation might easily have dissipated these errors, have remained silent. No sound public opinion will be formed on the subject, until the spirit of investigating these matters be infused among a new and larger class of the community. Circumstances point to the medical profession as the quarter whence the public may reasonably demand the rectification of unsound views of human mortality. The public have recently incurred an undisputed loss of some hundreds of thousands of pounds for want of the desired information. The Government has been selling annuities on old lives, upon principles well known to be false by all qualified persons. Mr. Hickman's remarks

on the subject are highly amusing,—he suggests that the names of the purchasers should be published. According to his views, the public indignation ought to fall on the buyers, and not on the pretenders to knowledge who advised the Government to sell commodities at less than their true value.

All writers on the subject are unanimously of opinion that there is only one correct way of arriving at the knowledge of the law of mortality of any population, which is comprehended in observing—the number living, and the number dying, at given intervals of age. The observation may be made, and all the essential results may be obtained, by any person of the most ordinary capacity and acquirements. A table of three columns is to be prepared; the first column containing the extent of human life divided into quinquennial intervals of age from birth upwards. In the second column are then to be placed the numbers observed to be living at the intervals of age expressed in the first column. In the third column are to be placed the observed number of deaths corresponding to the same intervals of age. If a fourth column be added, containing the quotients of the dying by the living, at the successive intervals,—this column will express the law of mortality of the population observed. This fourth column will contain the substance of all the information sought, and is equally attainable by the inexperienced as well as by the experienced in these matters. What is technically called a "table of mortality" consists in expressing for single years of age, the rates of mortality, agreeing, when combined, with the rates of mortality observed for quinquennial or decennial intervals of age. The skill of the calculator is, or ought to be, measured by the degree of uniformity with which he makes the annual rates increase or decrease, at the same time never deviating from the given facts for larger intervals of age. The Carlisle table of Mr. Milne is extremely defective in this respect; the rates for successive years of age rise and fall suddenly in a degree without example in any other table. I have published a table agreeing equally well with the observed facts at Carlisle, in which the annual rates increase with a degree of uniformity not found in the tables of any other author.

The mainspring of the errors circulated by Mr. Rickman through the government press, appears to be the defective construction of the "Northampton Table." Dr. Price, the author of this table, is, however, the last person to whom any blame can be attached; for no one has explained better by word and by example the only correct method of investigating the laws of human mortality. Because Dr. Price, having no information respecting the ages of the living in the town of Northampton, was compelled

to have recourse to hypothetical numbers; Mr. Rickman has absurdly had recourse to hypothetical numbers when the true number and ages of the living were placed before him. Indeed this is representing the affair in too favourable a light. For Dr. Price, before adopting the hypothesis of the population being stationary, collected a great multitude of facts to prove that such was nearly the case at the time he wrote. But Mr. Rickman adopts the hypothesis of the population being stationary, and at the same time admits that the population of England was then increasing with a rapidity never before heard of in a long-settled country.

Mr. Rickman, in divesting himself of the gross errors with which he has disfigured his literary productions, displays more caution than candour. He attempts to transfer the blame, justly due to himself, to continental writers. He cunningly reproves them for adopting the hypothesis of the "population being stationary," and conceals from his readers the fact that he is the only person who has carried this hypothesis to an absurd length, and this when the making of any hypothesis as to the ages of the living was the acme of absurdity. The errors consequent on adopting this hypothesis are comparatively small among continental nations, on account of the generally slow increase of the population; and the adoption of this defective hypothesis is excusable where the ages of the living have not been ascertained. Mr. Rickman has lately discovered that he is "a person not qualified for arriving at ultimate results," and he has consequently associated with himself a professional calculator. Whether his assistant is able to calculate correctly we have little means of judging; because any statement of the precise connection between the materials and the alleged results is carefully and suspiciously withheld. The results published at second-hand by Mr. Rickman, have been gradually approaching the results stated by me in THE LANCET.

On the 5th of December there appeared a statement in THE LANCET, that the mean duration of female life at birth in England and Wales was 43.70 years. In a medical periodical of the 19th December, Mr. Rickman states the number for England to be 43.7 years. The publication of the table which coincides in such an extraordinary degree with mine, is an object highly to be desired. In the same number of THE LANCET I made a statement founded upon opinions of Mr. Rickman loosely expressed in the Population Returns, that my results would be found to differ only one-twentieth part from results consistent with Mr. Rickman's estimated deficiency in the registered deaths. One fortnight afterwards, the results which I called for, made their first appearance, as seen by the following table:—

TWO STATEMENTS of the Annual Mortality of Females in England, (1) published in THE LANCET of December 5, 1835, the other by Mr. RICKMAN on Dec. 19, 1835.

Between Ages.	Rickman.		Edmon
	One out of	Or, out of 100 Living	Out of 100 Living
0 — 5	23	4.35	4.60
5 — 10	158	.63	.67
10 — 15	201	.50	.52
15 — 20	138	.72	.76
20 — 30	102	.98	1.04
30 — 40	85	1.18	1.24
40 — 50	71	1.41	1.49
50 — 60	49	2.04	2.16
60 — 70	25	4.00	4.12
70 — 80	10.8	9.26	9.69
80 — 90	4.9	20.40	21.16
90 — 100	2.9	34.50	37.19

The results which I have stated for England and Wales coincide almost exactly with the results of my theoretical table of "Mean Mortality" which I published four years ago, together with a complete and most extensive series of life insurance and annuity tables founded thereon. According to this table, the mortality at every age (excepting the period of infancy) is twenty per cent greater than that indicated by the Carlisle Table. Mr. Rickman and his assistant now admit the facts to be within five per cent of my statement, and they consequently admit that the mortality in England is fifteen per cent higher than that shown by their previously adopted but now abandoned Carlisle Table.

I have been lately informed that Mr. Milne himself, the promulgator of the Carlisle Table, has made a tardy acknowledgment of errors with which he must have been acquainted for several years past. He now admits that the mortality under five years, out of 100 born, in all England, is 24 instead of 32, as he previously stated. He has, however, apparently admitted only two-thirds of what he knows to be the real error. Mr. Milne, on the publication of his table, gave "a proof" of its coincidence at all ages with the mortality of the English population. His admission, therefore, that he had greatly over-estimated the mortality in infancy, is tantamount to the admission that he had greatly under-estimated the mortality at every age above fifteen years. The Carlisle Table may, therefore, be considered as abandoned by its parent.

46, Regent-square, London;
January 18th, 1836.

ARREST OF VOMITING BY CREOSOTE.

To the Editor of THE LANCET.

SIR,—The following cases of stomaclic disease, treated by creosote, are at your service, for insertion in your valuable Journal. I remain, Sir, your obedient humble servant,

GEORGE BODINGTON.

Edrington, Warwickshire, Jan, 13, 1836.

CASE I.—Mrs. S., a young married lady, the mother of one child, experienced a most difficult labour about two years since, the operation of "turning" having been resorted to, in consequence of an unusual presentation. She has since suffered from relaxation of the uterine system, irregular menstruation, hysteria, and constant sickness, and, on one or two occasions, from uterine hemorrhage; but the most distressing of her complaints has been an almost daily vomiting of food, some hours after taking it, at intervals of two, four, six, or eight hours, the food always returning in an undigested mass, whatever length of time may have elapsed from the period of taking the meal. Thus the dinner, taken at two o'clock p.m., would frequently remain on the stomach until four a.m.; and then be rejected in the same state as when taken, the only change being that produced by mastication. She complained also of a sensation of tightness and constriction across the chest, headache, and so much dimness of vision, as to amount almost to blindness; her countenance looked bloated and pale,

the pulse was small and feeble, and she had a constant feeling of weariness and prostration of strength. She had been for some months under medical treatment without benefit. She visited Cheltenham in the course of the last summer, and consulted some of the most eminent medical men there with no better result. Returning home in the autumn, she again came under my care, and having read in *THE LANCET* an account of Dr. Elliotson's success in the treatment of similar affections by creosote, I tried that remedy, mixing six drops of it in a little mucilage, with six ounces of water. The patient took but two large spoonfuls of this mixture, when a remarkable change took place in every respect for the better. She remained without sickness a whole day and night, which had not been the case any time for six months previous. Her features looked more natural, the headache and dimness of sight disappeared, the catamenia shortly afterwards occurred in a more natural and copious flow, and she appeared as if cured by magic, so sudden and decided was the effect; but being of an irresolute mind, I could not prevail upon her to continue the medicine, on account of its nauseous flavour. She had taken but one dose, and in a few days after enjoying her comfortable change, she began to experience a return of the symptoms; I then prevailed upon her to take a pill twice a day, containing one drop of creosote in two or three grains of aromatic confection. She continued this for a few days, and remained afterwards perfectly well.

CASE 2. The next case occurred in the person of an infant, about eleven months old; the sickness continued daily for a month, and resisted all means employed to subdue it. This, like the last, seemed to consist in a suspension of the process of digestion, as the mother informed me that rice given to the child for dinner at two o'clock p.m., was rejected the next morning from the stomach, unchanged in any respect. Indeed, this was the case with all the food the child took. It was rejected, frequently many hours afterwards, unaltered. The consequence was, great prostration of strength, with flaccidity of the muscles, pallid countenance, &c. One drop of creosote, in an ounce and a half mixture, was administered, giving one teaspoonful three times a day with the completest success. The infant perfectly recovered, and needed no more medicine.

Remarks.—I think these cases corroborative of the remarks of the learned professor of University College on the powers of creosote, and I am the more induced to transmit them for publication, seeing that some of your correspondents manifest a criticising disposition towards the lecturer. One doctor says that he has not read "his book," another that he does not fit his

"case," so that if the Doctor's views and practice do not exactly correspond with those of all the carping critics who may exist from John O'Groat's to the Land's End in Cornwall, judgment must be pronounced against him. For myself I am content to know that the learned Doctor is engaged diligently in reading the great book of nature, and own myself indebted for many valuable hints, derived from the perusal of his talented, judicious, and highly practical clinical lectures, as I have found them reported in the pages of *THE LANCET*.

CASE OF
FUNGUS MEDULLARIS
IN THE
CAVITY OF THE PELVIS,

By JULIUS WOLFF, M.D., Dublin.

A. P., 16 years of age, and of a slender habit, hail, except during some diseases in his childhood, been perfectly healthy, up to the period at which the affection about to be described made its appearance. When 15 years of age, he began to support his poor parents by dealing in various small articles, which he carried in a basket, the edge of which, as he walked, always pressed or struck against the upper part of the femur. One day he perceived on the inner side of the right thigh, about two and a half inches below Poupart's ligament, a swelling of about the size of a hazel nut, which increased by degrees and impeded the motion of the limb. He applied to a surgeon, who ordered him to rub it with mercurial ointment, and to apply cataplasms; but under the use of these means the swelling increased.

In the month of February, 1834, he applied to me in Hanover, where I was then practising. I found the swelling of about the size of a duck's egg, very hard, uneven, immovable, and insensible to the touch. The patient was in other respects very well, except that the swelling caused a feeling of tightness over the femur when walking, and, consequently, impeded his gait.

It could not be an inguinal or a femoral hernia, because the swelling had an irregular shape, was hard, uneven, and immovable, and its site did not correspond with any of the apertures through which herniae make their appearance.

It could not be a bubo, because the swelling was too far below the inguinal glands. It had lasted already seven months, and the skin which covered it presented its natural colour.

I had no reason to suspect the existence

of psoas-abscess, because the symptoms which precede and attend such an affection were not present, and no fluctuation was perceived.

I did not apprehend it to be fungous medulla, because the manner of its commencement and its course seemed to contradict the supposition.

I ordered the patient to rub the tumour with a mixture of mercurial ointment and iodine, and to employ, internally, Plummer's powder—(*Hydrarg. Chlorat. mit.; Stib. Sulphur. Aurant.*) This treatment effected no improvement; but a few weeks after I could move the swelling under the skin from one side to the other.

The patient having requested me to deliver him from the inconvenience under which he was labouring, I proposed an operation, as the surest and quickest means of getting rid of it. I expected that after having first made a longitudinal incision, and then detached the skin and fascia lata which covered the swelling, the remaining adhesions of the morbid mass could easily be detached with the fingers or the shaft of the scalpel.

Operation.—I performed the operation in the presence of two surgeons, Dr. Henniger and Mr. Lange. After I had cut through the integuments and fascia lata, a convolution of dark-blue vessels, and a cartilaginous mass, closely intermixed with each other, were forced out of the wound. They were enclosed in a white, thick, tendinous membrane, and felt hard to the touch. I introduced a dissecting hook into the morbid mass, with which I drew it forth, and tried to separate the adhesions with the fingers and knife, by which means it came more fully into view. Further examination with the finger showed that the mass had more extensive attachments than was at first apprehended, that it went both deeper between the muscles, and higher towards Poupart's ligament. I enlarged the incision in the skin, and the morbid mass, which was firmly adherent to the muscles, was, with great care, separated, and the muscles were thus laid perfectly bare.

To my great alarm I found now that the morbid mass passed below Poupart's ligament, into the abdomen, and could not be drawn forth, nor could I introduce my finger, to separate the adhesions. I had thus got into a difficulty, which, however, I endeavoured to conceal from the many persons who were present at the operation, until, after more accurately examining the wound with my finger, and reflecting a few moments, I came to the resolution of making an incision through the integuments, above Poupart's ligament, in such a manner as is practised when we wish to take up the common iliac artery. Through this incision, which was about two or two and a half inches long, I introduced the first and

second finger of my left hand, under the sac of the peritoneum, to the psoas muscle. Here I discovered a soft morbid mass, which covered a part of this muscle, and which could easily be separated from it by the fingers. After this was done, I found no difficulty in separating that morbid portion which adhered to Poupart's ligament, and drawing forth the mass which I had just before separated with my fingers from the abdomen. The part thus separated was of the weight of nine and a half ounces.

Morbid appearances.—On examination of the morbid structure, it was found that the part which had been situated out of the abdomen, and which had felt so hard and uneven, consisted of dark-blue dilated and contorted vessels, mixed up with a cartilaginous mass, and little granules of fat, all of which were enclosed in a thick white fibrous tunic. The part situated in the abdomen was soft, like the substance of the brain, attached together, of a gray-white colour, intermingled with a great number of minute red vessels, and enclosed in a thin white membrane. In short, it had all the characters of medullary sarcoma.

Whether the disease took its origin internally or externally it might be difficult to decide positively. To me however it seems most probable, that the fungous mass in the cavity of the pelvis was of a later date than that situated on the thigh, because the patient had never complained of general indisposition, and any inconvenience he had suffered was limited to the external swelling alone.

Progress.—The wound above Poupart's ligament was soon healed up by being simply brought together with emplastr. adhaesiv., whilst the larger wound below Poupart's ligament was dressed with simple ointment. The patient was put to bed, and an appropriate diet was ordered. Except a very slight degree of fever, which appeared in the evening of the 3rd day after the operation, the patient went on very well. His appetite and sleep were good, and the bowels regular. The wound looked well, and suppurated but little. A few days after, he was able to be out of bed, and could walk up and down the room. In the fifth week he went out of doors, without, however, returning to his former occupation. The wound gradually became smaller, and gave issue to but little matter, and that of a good quality.

In the seventh or eighth week after the operation, one afternoon, a sudden bleeding from the wound took place, without any known cause, and to such a considerable amount that the patient was almost exhausted. Cold applications were used, and the bleeding was thus checked. I was unable to discover the source of this hemorrhage. It returned frequently, but in smaller quantities, and was always checked by the

application of cold water. After a few weeks the patient got a cachectic look, became low-spirited, and lost his appetite. He had, during the day, at irregular intervals, horripilations, and, towards evening, a degree of low fever. The wound assumed an unfavourable aspect, and ceased to secrete healthy matter, but poured forth, in place of it, serum in great quantities. Out of the bottom of the wound a brain-like mass again shot forth. Light nourishing diet was now ordered, together with the decoction of the cinchona bark, with sulphuric acid, whilst, externally, fomentations, with the same decoction, and alum, were given. The patient apparently rallied. His appetite returned. In the evening the fever gradually left him, the wound had assumed a somewhat better appearance, the morbid substance was secreted in large quantities, and the secretion of the serous fluid decreased.

The patient continued to be in this favourable state for a few weeks, and the wound appeared becoming less. But he had, now and then, slight fits of intermittent fever, of the tertian type, which was endemic in the village in which he lived; but this was soon checked by using the sulphate of quinine.

In this state the patient remained for a few months. His strength apparently increased, the wound became smaller, and secreted but little of the fluid mentioned. The cachectic appearance of the patient, however, did not leave him, though he said that he felt very well. The wound, which was now about the size of half-a-crown, became again of a whitely appearance, and anew secreted a very considerable quantity of the above-mentioned fluid, so that the patient was constantly wet with it. He grew thin, got evening-fever, and had a dry cough, lost his appetite, and was obliged once more to be constantly confined to his bed. This excessive secretion lasted for six or seven weeks, until at length, by the steady use of external and internal tonic and astringent remedies, it, to a certain degree, diminished. The patient, however, was visibly wasting away; the dry cough was now very teasing, and the bark no longer agreed with him. I ordered *Decoct. Lich. Island., Pulv. Sulph. Aurant., Antim., et Extr. Cicul.*, which diminished the cough. Soon after, however, colliquative perspiration and diarrhoea made their appearance, together with expectoration of matter, and gangren. decubit., on the os sacrum, and aphthæ in the mouth, so that the patient was unable to swallow anything.

In the thirteenth month after the operation death ensued, the patient being in a state of extreme emaciation. The examination of the body was not permitted.

34, Nassau-street;
Dublin, Jan. 11th, 1836.

PHENOMENON OF THE PULSE.

To the Editor of THE LANCET.

SIR,—The following is transmitted for insertion in a corner of your periodical:—

Staff-assistant surgeon Dr. Hopkins, having occasion to be absent from town for twenty-four hours, requested me to take medical charge of the detachments, stationed in St. John's, for him until his return. On doing so, he stated that he had been called in the morning to see one of the sergeant's wives, who appeared to be labouring under an attack of modified epilepsy. He had ordered an aperient and an injection. About four hours after (at two p.m.) I visited the patient, and found her presenting the following amongst other symptoms:—Complete coma; the pupils dilated; pulse full, soft, and between 80 and 90. On inquiry, I learnt that she had complained, on the previous day, of headache, and had, on the same evening, got drunk, being accustomed to tipping. I ordered fifteen grains of calomel, immediately to be followed by a solution of sulphate of magnesia (ʒi to ʒviij of water, ʒij. ʒm. 6. post. calomelan), wet cloths to the head, and fomentations, and bottles filled with hot water, to be applied to the soles of the feet, the calves of the legs, &c. While I was standing by her side, with the finger on the pulse, she was seized with a sub-epileptic fit, experiencing twitches of the muscles of the face, of the superior and inferior extremities, &c. The pulse, from being full and soft, became a mere thread, and quicker and harder. I was struck with the phenomenon, as I could not bring to my recollection having ever read of such an occurrence during epilepsy, and on reference to my books, I have not been able to find the circumstance recorded. I have conversed with most of my medical brethren here, some of whom have retired from practice for ten, fifteen, or twenty years, but not one of them has ever met with such an occurrence. It is from this circumstance that I have ventured to request the insertion of some particulars of the case. One of two causes must have occasioned the diminution of the pulse's volume, either a muscular "vis insita," partaking of the influence of the epileptic seizure, or pressure of the muscles of the arm and fore-arm. But if the latter was efficient, would not the artery, where it is superficial, at the wrist, rather have increased in volume than otherwise? For if we fill a flexible tube with a fluid, and apply a compressing force to two-thirds of its extent, the remaining third will increase in volume, as a matter of course, if the tube be dilatable. I have always been disinclined to allow the claim of muscularity of the arteries; but this case has, I confess, a little staggered my creed. The woman did

well, the medicing acted copiously, and next day she complained of nothing but headache and debility. I am, Sir, your obedient servant,

JOHN FURLONGER, M.D.

St. John's, Antigua, Dec. 12, 1835.

RESUSCITATION FROM DROWNING.

To the Editor of THE LANCET.

SIR,—My connection with the *Royal Humane Society* as one of its medical assistants, and the vicinity of my residence to the receiving-house in Hyde Park, have led to my being called upon to treat most of the cases of submersion requiring medical aid which have occurred in the Serpentine for some years past. I was there on Christmas-day, at the time of the accident which, unhappily, was attended with the loss of seven lives, and took an active part in the treatment of the sufferers.

A committee of the society met to inquire into the circumstances of this fatal occurrence, and the notices of their report in the newspapers have produced a long leading article in the *Medical Gazette* of the 9th inst. on "The Humane Society and its exertions." The writer entertains the most preposterously absurd notions relative to asphyxia from submersion and resuscitation, and is, in consequence, quite unable to conceive how seven persons could have been lost, out of fifteen taken out of the water and brought into the receiving house, unless there existed a fault somewhere. He, however, lauds the society, and admits that it exerts itself to the utmost of its means. In reference also to the medical men who gave their gratuitous assistance on that day, he says, "It must not for a moment be supposed that we mean to impute the slightest deficiency of skill to the gentlemen employed. * * * The fact is undeniable that here were fifteen bodies all at once, and under one roof, to be attended to by seven medical men. In this view of the case, perhaps, many will rather be surprised, that so many as eight were recovered."

I have not, therefore, any charge against the society or its medical assistants to rebut, for none has been made. My object is to point out in your valuable journal the erroneousness of the opinions before alluded to. I do not fear that the veriest tyro in the profession will be misled by them, though coming clothed with editorial authority. But it is more than probable that they may confirm the errors, and distress the minds of some of the many non-professional persons who read the medical hebdomadales. The fairest way is to quote the words of the writer. He says,

"Some worthy old authors have headed

down to us histories of recovery, when the submerged had lain sixteen hours, three days, and even seven weeks, in the water. But as we believe that the age of miracles did not extend to the seventeenth century, when these facts are related to have happened, and as we have reason to think that human beings were not differently organized formerly from what they are at present, we must respectfully decline giving credence to the marvellous stories aforesaid. We can believe, however, that there have been some rare cases of recovery where individuals have remained above an hour in the water."

The writer here evidently means under the water. Again, after observing that where submersion is accompanied by apoplexy, the instances of recovery are extremely rare, he adds,

"Not so where syncope occurs, as when a person faints with terror at the instant of submersion, or immediately before; for in this state, as is known, respiration may remain suspended for a period more or less considerable, and probably the greater number of those cases which seem most anomalous, where recovery has been effected after a *sojourn of two hours or upwards in the watery element*, have been of this description."

Here, also, I presume we must read *under*, instead of *in*, the water, for persons have been many hours in the water, without having respiration suspended at all. I shall trouble you with only one more quotation. The writer says,

"In the Paris arrangements for the resuscitation of the apparently drowned, twelve hours are taken as the *maximum*, beyond which there is no hope. Where it is ascertained, for instance, that a person has been eleven hours submerged, no means of probable succour are left untried, and the result of this practice is highly satisfactory." (!!!)

The result in every such case would, of course, be precisely similar to that of endeavouring to reanimate the bodies of the unfortunate persons whose heads have been struck off by the guillotine, and as it is highly satisfactory to our writing Parisian friends, I suppose we shall soon hear their labours in this new work of charity. Equally vain and fruitless would be the ablest exertions to resuscitate those who had been *two hours, or even one hour, submerged*. The medical assistants of the Royal Humane Society are too well informed to make such ridiculous and futile attempts; but frequently in cases of submersion for shorter periods, where there is a possibility of success, they do institute and persevere in the use of means, out of respect for the feelings of relatives, or of the bystanders.

The experiments of the ablest modern physiologists, and the opinions of the latest approved writers on asphyxia, concur with

the result of experience in showing, that there is little chance of resuscitation after a body has been more than five consecutive minutes under the surface of the water. I doubt whether the *Royal Humane Society* possesses any well-authenticated record of a single case of recovery after the body had been submerged more than five minutes. I believe that every one of the seven persons who met their death at the Serpentine on Christmas day, had been more than that time under the water—some of them, I know, and perhaps all, very much more. It is not at all marvellous, then, that they were not restored. I am, Sir, your very obedient servant,

GEORGE WOOLLEY.

8, Brompton-row, Jan. 19, 1836.

*. The above letter reached us last week, but too late for insertion in our Number for Jan. 23rd.—Ed. L.

STRANGULATED INGUINAL HERNIA.

To the Editor of THE LANCET.

SIR,—At the suggestion of my friend Dr. Lubbock, who witnessed the following case, I am induced to submit the same to you, requesting that you will insert it in your Journal, and I shall be glad to be made acquainted through your pages with such observations as may suggest themselves as to the treatment to be adopted under similar circumstances on a future occasion. I remain, Sir, yours respectfully,

W. G. GOWING.

Norwich, Dec. 31, 1836.

CASE.—Nov. 7, 1835. Mr. Lambert, æt. 30, of a robust constitution, by trade a baker, was, on Saturday morning, whilst lifting a sack of flour, suddenly seized with a severe pain in the lower part of the abdomen, which continued above an hour, when he became sensible of a swelling in the left groin, which gave him considerable pain on pressure, and continued to increase until about ten o'clock, when I was summoned to attend him. I found him suffering acute pain about the umbilicus, and vomiting everything which he drank. In the left groin there was a swelling, very tense, of an oblong shape, of about the size of a hen's egg. Descending about one-third down the scrotum. I placed him in a supine position, and relaxed the abdominal aperture, by raising the limb on the diseased side, and attempted to return the intestine. The swelling was so exquisitely painful as almost to exclude the application of the taxis. Not succeeding, I administered a tobacco enema, and took away above twenty ounces of blood from the arm. He complained of sickness, but did not faint. I renewed the taxis, and

in about ten minutes succeeded in returning the bowel. Ordered one grain of opium.

Eight o'clock. Vomiting continues to harass him; pulse 100; great thirst, and a general restlessness. Laxative injections ordered, which brought away some hard feces. A mixture composed of salts and senna, with five grains of calomel, every four hours.

Nov. 8. Nine o'clock a.m. No sleep; pulse 110; vomiting through the night; tongue clean; slight pain in the bowels, which was not increased on pressure; no motion. At four o'clock the symptoms remained the same. At ten I visited him again, and finding that his bowels had not been relieved, and that the vomiting continued, I gave him another laxative injection, which brought away more feces, and ordered a pill composed of a third of a grain of opium and two of calomel, every two hours.

9. He could not lie still for more than a very few minutes; frequent vomiting; pulse 110; tongue clean; occasional pain, which appeared to arise from spasm, as it came on by paroxysms; nearly all the muscles of the body, particularly those of the legs and arms, were affected with spasm. Dr. Lubbock was requested to visit him, and he prescribed one drop of croton oil, and five grains of calomel every four hours, with the effervescent mixture. We met again in the evening, but with no better prospect. Every kind of nourishment was rejected by the stomach; pulse 120; no relief in the bowels.

10. Passed a restless night, took some coffee, which remained on the stomach above an hour. Strength considerably reduced; pulse more feeble and frequent; countenance shrunk, and the mouth frequently filled with a bilious stercoraceous matter; he died at about half-past four.

Post-mortem Examination, Six Hours after Death.—On opening the abdomen, the portion of strangulated intestine, which consisted of a knuckle of ileum, about two inches in length, was of a dark-brown colour, and adhered firmly and generally to the sac, which so completely encircled its upper portion, as not only to obstruct the passage of the feces through the large intestines, but also the circulation of the blood. Its parietes were thickened, and infiltrated with blood, its external surfaces (the peritoneal covering) firmly adhering together. Its extreme points rested just within the internal ring, which permitted the finger to enter freely, as also did the external ring. The abdominal viscera generally, presented a healthy appearance, except that portion which immediately covered the tumour, which was slightly ecchymosed, probably in consequence of the taxis. The stomach was perfectly empty, and very much contracted; the intestines,

as far as the strictured portion, were distended with liquid feces and gas.

Might not my patient's life have been preserved, if, thirty hours after the hernia was returned, an incision had been made so as to expose the abdominal ring, the bowel (which would have been seen) been drawn down, and the hernial sac slit open?

COPAIBAL RHEUMATISM.

To the Editor of THE LANCET.

SIR,—I read in the last Number of your able Journal the communication of Mr. Eagle relative to the circumstance of copaiba producing the disease termed "gonorrhoeal rheumatism," and beg to add my testimony as to the correctness of the views he has taken upon the subject.

It has fallen to my lot to attend a great number of venereal affections, but in no one instance have I seen gonorrhoeal rheumatism produced unless copaiba had antecedently been exhibited. I have now before me notes of a case which came under my treatment last winter, in which the most distressing symptoms supervened on the use of the above medicine. The synovial membranes of the knee were greatly enlarged and indurated; the dorsum of each foot was swelled, and the pain was so excruciating, that the patient was unable to put his feet to the ground for a period of six weeks. His medical attendant pursued (very properly) antiphlogistic measures, such as local bleedings, saline purgatives, &c., but at the same time prescribed a copaiba mixture. When I was called in to see the patient, I found him labouring under great nervous excitement, and he was exceedingly emaciated; pulse 30; numerous petechiæ on different parts of the body; much fever present, and, altogether, he was in a very precarious state. I immediately ordered a discontinuance of the copaiba mixture, but at the same time directed that he should persist in the use of the fever mixture, and that the local bleeding should be renewed. Having pursued this system for a week, he declared himself to be quite "another man," and was enabled to follow his usual occupation. The discharge ceased upon his using an injection composed of the *Plumb. Superac.* and the *Zinc. Sulph.*

I might give you other cases, but refrain from doing so, in order that I may not encroach too much on your valuable columns.

I am, Sir, your constant subscriber,
W. B. MADDOCK, Surgeon.

London, Jan. 19th, 1836.

CÆSAREAN OPERATION,

TERMINATING FATALLY FOR THE MOTHER
AND SUCCESSFULLY FOR THE CHILD.

THE following interesting case, attended and related by Dr. B. G. KRANEFUSS, in *Russ's Magazine*, will be found in No. 2, Vol. 45, of that periodical, the last-published number of the journal:—

The subject of the case was a female, forty-two years of age, who was now pregnant for the first time. The author was called on to attend her on the 18th of March, and found that she had been in labour since the 15th. The midwife in attendance had made several improper attempts, with the hand introduced into the vagina, to change the position of the child, and, moreover, had exercised very violent pressure on the sides of the abdomen, in order, as she said, to hasten the birth of the child. The whole abdomen was now excessively painful; the external organs very red, and also painful. On introducing the finger, which caused a good deal of pain, into the vagina, and exploring the pelvis, the antero-posterior diameter of the inlet was found not to exceed two inches; the child's head presented at the os uteri, which was open, and the motions of the infant could be distinctly felt. The Cæsaean operation was proposed, and approved of, in consultation, by Dr. Warenstoffs, who had performed it twice, and once successfully, for both mother and child.

The patient was a woman of short stature, and evidently deformed by rickets, from which she had suffered in her youth. During the period of pregnancy she caught cold, and still coughed a good deal. The pelvis was much inclined forwards; the distance of both superior anterior spines of the ileum was eleven inches, and the conjugate diameter twelve inches; the conjugate diameter of the inlet was estimated at two inches.

The patient having consented to the operation, the surgeon's first care was to empty the bladder and intestinal canal. The woman was now placed in a bed prepared for the purpose; two assistants held her feet; another, placed at the head, took charge of the arms; a physician, aided by a midwife, was stationed on the left side, and entrusted with the important duty of preventing the intestines from protruding during the operation. It was impossible to procure sponges, which are recommended by *Gratze* and *Hedenus*, in the house of this poor female; their place was, therefore, supplied by folding up a sheet in an elliptical form, and placing it over the front of the uterus, while proper persons took care that it should be applied equally to all the abdo-

migal parietes. The uterus seemed to lie in the middle of the hypogastrium; the first incision was, therefore, made in the linea alba, and successive layers of the abdominal wall were divided, with caution, down to the peritoneum, into which an opening was finally made; the division of the soft parts terminated at one inch and three quarters above the pubes, and extended upwards for five inches and a half.

The uterus now presented itself to view, and an incision was made, in the direction of the external wound, about one inch in length. This was immediately prolonged upwards and downwards, with the bistoury, to the length of five inches and a quarter. The child lay with its back forwards, and the operator proceeded to seek his feet, but was unable to succeed in reaching them, from the contractions of the uterus; the same cause rendered it impossible to seize the head; it therefore became necessary to enlarge both incisions downwards by half an inch; the child was then extracted, and although the uterus contracted strongly, no bowel protruded through the wound; however, the state of the infant requiring some assistance, and the person intrusted with the care of the abdomen having turned a one side to aid the nurse, a knuckle of intestine escaped, but was immediately reduced. The wound was now sponged with warm water, a roll of charpie dipped in oil was placed between the uterus and abdominal parietes; two stitches were applied, and the end of the roll was brought out from the lower angle of the wound, which was left open for about one inch and a half; strips of sticking plaster were also wound round the abdomen, and the wound was covered with a compress dipped in oil, and the whole was retained by a bandage.

Immediately after the operation the woman felt herself well; the pulse, sixty-two before the operation, had mounted only to sixty-five; the only bad symptom was a slight attack of vomiting, which came on immediately after the patient was placed in bed. She was ordered to take a teaspoonful of the following mixture every hour:—*R Decoct. Semen. Lini* ʒvj; *Extract. Hyos. ciam.* ʒj; *Olei Amygd.* ʒj; *Syrup. Althææ* ʒss.

In the evening the patient's pulse had risen to 84, hard and full; the face coloured; the whole abdomen painful. The symptoms were immediately relieved by an abstraction of twelve ounces of blood.

20. Morning. She passed a quiet night, and seems in a favourable state; pulse 65, pretty strong; the lochia now come away, and a bloody serous fluid is discharged from the inferior angle of the wound. The urine is not discharged by voluntary efforts; the use of the catheter is necessary. The cough which existed previously to the operation is much diminished.

As to the child, it was a full-grown male well formed, weighing seven pounds and a half, and twenty inches long. The antero-posterior diameter of the head was four inches and a half; the transverse three inches and a half; and the mento-occipital five inches; the breadth of the shoulders four inches four lines. In the evening the woman was pretty well; however, the pain returned in the right side of the abdomen; pulse 75.

21. Morning. The physician was sent for to return a portion of intestine that protruded through the inferior angle of the wound during a fit of coughing. This was returned, and fresh plaster applied, so as to close nearly the whole wound. A clyster was administered without any effect, and henceforward it was constantly necessary to introduce the catheter. *Mid-day.*—The pain in the right side of the abdomen has become very violent, and extends down to the inguinal region. It is diminished by leeching and cold applications.

R Amygd. Recen. Excortiat. ʒj; *f. terendo cum aqua; Valer. q. s.; Emulsio* ʒvj; *Ext. Hyosiam.* ʒj; *Aquæ Lavrunceras* ʒijj; *Syrup. Althææ* ʒj; a spoonful every hour.

R Opii gr. 4; *Sacch. Albi* gr. x; *f. pulv.* D. S.: to be taken in one dose. A lavement was given without any effect. In the evening the pulse rose to 90; the cough had diminished, and the pain in the abdomen was supportable.

22. Morning. The patient assures us she feels well; the pain has not increased; but the cough is now more violent.

R Opii gr. 4; *Sacch. Albi* gr. x; *f. p.* The two last clysters given have not yet opened the bowels. Towards evening the patient became excited from the numerous visits she had received during the day, and the pulse rose to 112. In the night she coughed a great deal, and the pain of the abdomen became much worse. The epigastric region was now tympanitic, and an evacuation could not be obtained by clysters.

R Olei Ricin. ʒiss; *Vitel. ov.* No. ij; *Aquæ Valer.*, a. s. ut *f. terendo emulsio* ʒvi; a spoonful every half hour.

R Opii gr. 4; *Eleosacch. Fleniculi* gr. x; *f. p. deut. tal.* Dos. vi. S. One powder every two hours. The cough was appeased by a few doses of this powder; aromatic fomentations were applied to the abdomen.

23. A discharge of some wind has taken place, but no stool; the pain is less; pulse 100; the urine red, taken off by the catheter. The wound has a good appearance, and union has already commenced.

24. Vomiting of a foul-smelling matter during the night; pulse 96; the countenance agitated.

R Olei Ricini ʒiss; *Gummi Mimos* ʒj; *Vitel. ovi unius*;—*Aq. Menthe Piper.*, *Valer.*, aa. ʒijj; *f. l. a: emulsio, cui addc Syrrup.*

Manna ʒi: a spoonful every hour. A lavement with assafoetida.

Evening.—No stool; pulse weak, 104; another clyster brought away some wind, which gave the patient relief; she has slept but little since the operation; the cough is much diminished; the tongue is covered with a thick yellow crust.

25. The dressings were reviewed to-day; the wound seemed partially united, but the stitches remained firm. An ill-conditioned pus was discharged from the ununited points, especially when the abdomen was pressed laterally. During the night the patient made several efforts at stool, and passed some hard feces; pulse 110; abdomen still painful. The tendency to tympanitis is now evident; the patient is delirious, especially when awakened from sleep. The lochia copious, purulent, and fetid.—*R Rad. Caryoph., Valer. Min., aa. ʒss. Infunde Aqua Feruid. ʒvj. Stent per 4 horā vas. tēc.; colaturā adde Extr. Hyosey. gr. xv; Ether. Sulphuric. ʒss; Syrup. Althae ʒj: aspoonful every two hours.*

26. The nervous symptoms continue; the tongue is brown; great thirst; the patient complains of great pain; one stool of hard feces; pulse small, 115.

27. Pulse 96, more developed. The urine was passed for the first time without assistance, and is less red. On dressing the wound, its upper edge was found to be united. When the abdomen is pressed upon, the face gives sign of pain; appetite completely lost; thirst; no stool, though a clyster is administered twice a day.

28. The pain of the abdomen has become more acute and general. The patient received some alleviation after the application of cold compresses. An almond emulsion, with *Tinct. Opii* and *Aqua Lauro-ceras*, was ordered. Pulse 120.

29. The pain in the right side of the abdomen is very acute. The patient is much agitated, and cries out in agony. The face expresses great suffering, and has taken on the hippocratic cast. Pulse 140, small, and weak. Aromatic fomentations to the abdomen do not produce any effect as before.

30. A knuckle of intestine has given way, and the feces issue in great quantity through the inferior angle of the wound. Pulse 100, excessively small; face collapsed; abdomen less painful; hands and feet stone cold. The patient sank on the following day, 31st, with the common symptoms of gangrene of the intestine.

Body Examined on the 1st of April.

The edges of the wound, except inferiorly, were so closely united, that it became necessary to divide them with the bistoury. The abdominal contents, with the exception of the uterus and great intestine, were normal. The uterus was contracted to the size of a man's fist. Its inferior segment

filled the inlet of the pelvis so much, as to oppose some resistance to its separation. The wound of the uterus was now only one inch and a quarter long, and the edges were filled with healthy granulations. We could observe no appearance of the intestine having been strangulated in the wound. The posterior surface of the uterus was tumefied, and of a deep-red colour. The whole of the colon, as far as the sigmoid flexure, was filled with hardened feces. Several deep-red spots were seen on the transverse and descending colon, but no gangrene. The anterior wall of the ascending colon was gangrenous throughout, and near the cæcum appeared two orifices, through which the feces escaped into the abdominal cavity. These openings corresponded in size with two roundish prominences of from one to two lines elevation, which existed on the posterior surface of the uterus. In this part only was there a deposit of yellowish fluid.

The pelvis of this patient was removed, and prepared for the museum of Munster; when measured, it was found that the distance between the antero-superior spines of the ileum was eleven inches; the conjugate diameter of the inlet two inches one line and a half; the transverse diameter five inches; the distance of the tuberosities of the ischia from each other, four inches. The child lives still, and is very healthy, a circumstance remarkable enough, if we reflect how much he must have suffered from the manœuvres of the midwife.

Rust's Magazine, No. 2, Vol. 45, contains a case, with a drawing, of medullary sarcoma, occupying the inferior surface of both hemispheres in front of the decussation of the second pair. The man was killed by an accident, and the symptoms to which this remarkable tumour gave rise could, therefore, only be collected from the report of his relations. We cannot award to them much value. We also find in the same number a very good delineation, with a detailed account, of Mr. Weiss's screw lithotrite.

CASE OF PARAPLEGIA,

ACCOMPANIED BY
NON-SECRETION OF URINE AND FECES,
DURING MANY YEARS.

Described in a Memoir read at the Academy of Sciences and Arts of Padua. By G. MONTESANTO, M.D.

ABOUT three years ago the author of the above-mentioned memoir communicated to the *Academy of Medicine* the history of an Italian prisoner who passed several years of his life without having excreted either urine

or feces. This man, who had become an object of great curiosity to the Italian physicians, died at length in prison, and M. MONTESANTO now detailed a complete account of his life and malady.

Dominica Valetto, at the age of 18 years, fell from a great height. The accident, which occurred so far back as the year 1816, was followed by weakness of the lower limbs, and a certain difficulty of excreting both the urine and feces. In 1818 he was committed to the jail of Padua for some crime, and after the lapse of a year, was attacked with inflammation of the spinal marrow. The patient's life was saved by the assiduous care of M. MENATO, but sensation and motion were completely lost in the lower extremities. The paralysis was soon joined by a new order of phenomena. Every day, five or six hours after each report, Valetto vomited all solid and liquid substances that he had eaten. The excretion of feces and urine was now completely suppressed, and in addition to the vomiting by which the meals were daily rejected, the patient was now accustomed, after an interval of a few weeks, to throw up a quantity of stercoral matter by the mouth.

The patient had already passed eight years in this condition, when in the year 1828 he was submitted to the care of M. MONTESANTO. From 1828 to 1831, the vomiting of stercoral matter became more rare than before that period, and even sometimes was absent during a very long space of time. However, the rejection of fluids was more frequent, and this coincided with a plethoric state of the body that rendered it necessary to bleed the patient no less than sixty times. The oppressed respiration, hard accelerated pulse, fever, pain in the chest, and malaise, caused many apprehensions of hydrothorax; in fact, he just escaped falling a victim to this disease in 1830, after a very severe winter, from which he suffered extremely. The unfortunate patient's cell receiving no artificial warmth, while he was unable to cover himself in consequence of the weakness of his limbs.

Under these circumstances M. MONTESANTO wrote to the judicial authorities, demanding, in the name of humanity and for the interests of science, that the removal of the patient to the civil hospital might be permitted; but the prisoner had been condemned to confinement for life, and the tribunal was inexorable.

In 1831 the habits of Valetto underwent some change; he preferred the coarsest and most heavy food. He refused altogether both and wine, but drank brandy in abundance. He expressed a great deal of suffering and disgust whenever any other food than his favourite choice was prepared for him. Thus on the 27th March 1832, a little fried fish which he ate against his will excited the most grave symptoms,—excessive cardial-

gia, pulse quick, and violent inflammatory fever, requiring repeated bleedings. Finally, after incessant though fruitless efforts, continued for fifteen days, which he passed without eating a morsel, after acute spasm of the stomach, and the exhibition of a pain in the back under which he suffered for several years, an unexpected vomiting of stercoral matter in great abundance came on, and towards the end of April the patient was restored to his former health.

At this period a violent shock of an earthquake threatened to overthrow the walls of his prison, and the patient was transported to another. During his passage he suffered severely from pain in the stomach and spine at each shock of the carriage. The spinal pain now became aggravated, and was accompanied with internal pulsations: the abdomen unexpectedly swelled, as if distended with air. This last symptom, though temporary, was the more remarkable, because hitherto the patient never complained of any painful sensation below the stomach, or in the region of the great intestine, the kidneys, or bladder, even while he suffered most severely in the neighbouring parts.

On the 20th Nov. 1833, Valetto was attacked with acute febrile symptoms, preceded by a sensation of coldness, and oppressive pain in the head. The fever was arrested by bleeding: the calm which generally followed this remedy was not now attained. Towards the middle of December his sufferings increased: the stomach refused to bear any food; he was depressed, complained of violent pulsations near the vertebrae in which the pain was usually seated, and in spite of frequent efforts was unable to throw up any matter from the stomach. The disturbance of the circulating and digestive organs was partially calmed by a copious bleeding; but the unfavourable symptoms soon returned: the epigastric region was now contracted, while the hypogastrium was hard and tumefied. After an access of very violent suffering, he threw up some liquid, inodorous, insipid matter, and then some bitter fluid. The region about the xiphoid cartilage now became the seat of a new pain; the hands and arms trembled. Towards the month of March 1834, the lower extremities became oedematous, and presented much of the appearance seen in phlegmasia alba dolens.

On the 12th May, Professor Fabris, chirurgien-en-chef to the Civil Hospital, visited the patient: he explored the state of the rectum, and found the gut very much contracted, and lined with an inodorous greenish mucus: the finger could not distinguish any portion of the bladder, and the patient seemed so fatigued from the examination, that it was not judged fit to introduce a catheter. The patient's health now declined from day to day: the tumefaction of the limbs began to decline, and at the same

time he passed a small quantity of urine through the urethra. The urine discharged was watery, nearly free from odour; sometimes he remained for several hours without passing any; at other times he excreted two pounds in the twenty-four hours. It is important to remark that he never had had either incontinence or retention of urine, and that it was never necessary to introduce the catheter, a circumstance so often required in paraplegic individuals.

At about the month of October he was again removed to another prison, in which he survived only three months. By degrees the impossibility of taking food was established; he vomited at once every liquid and solid substance as soon as swallowed.

On the 13th February 1835, the symptoms of an approaching death were visible, when a quantity of fluid feces, without any premonitory sign, was discharged simultaneously from the mouth and anus. Valetto expired thirty-six hours after this phenomenon, in the thirty-sixth year of his age, and after having suffered nearly seventeen years under this most distressing malady.

Post-mortem Appearances.

The autopsy was made on the following day, in the presence of MM. Brugnolo, Caldanì, Morgagni, Fabris, Montesanto, Argenti, and Méneghini. The membranes of the brain appeared to be cedematous, but the hemispheres of the cerebrum were firm and well developed; the cerebellum seemed small when compared with the cerebrum. The vertebral canal was normal: the point in which the violent pain existed during life did not present any alteration: in the cavity was found a large quantity of sero-sanguineous fluid: the chord itself was normal. In the abdomen the stomach was found much distended, and a great deal larger than in the natural state; from the great bulging extremity to the small cul de sac, it measured eight Paduan inches and a half; from the summit of the great end to the middle of the great curvature, seven inches. It contained a small quantity of bilious and fecal fluid: its parietes were healthy; the liver adhered throughout to the diaphragm: the gall-bladder, completely empty of bile, contained about twenty or thirty calculi. The external surface of the small intestines was in many points injected, and of a brown-red colour: they were contracted here and there, chiefly near the cæcum; they contained the same kind of fluid as the stomach. The cæcum, ascending colon, and a part of the transverse, were normal: from the iliac flexure to the anus, the intestinal parietes were thickened, resistant, and contracted: the inner surface was the seat of numerous ulcerations: the whole canal contained fecal matter,—in the small intestine, very fluid,—in the large, hard and dry. The liver and pancreas were healthy.

The bladder, excessively contracted, was concealed behind the pubes; its parietes were much thickened, and it contained a few drops of thick red urine; the cavity was not capable of holding more than three ounces of fluid: kidneys healthy; ureters flaccid, and a little contracted; the testicles and organs of generation healthy; the vesiculæ seminales contained a small quantity of seminal fluid.—*Annali Universali, October, 1835.*

DISEASES OF OLD PERSONS.

Clinical Researches into the Diseases of Old Persons. Made at the Hospital of Salpêtrière, Paris. By M. HOURMAN and M. DECHAMBRE. Archives Générales, Nov. 1835.

In a former Number we analyzed the first of these interesting memoirs. We now continue the series from the November No. of the *Archives Générales*, giving the statements nearly in the language of the authors themselves:—

The anatomical modifications, which the respiratory organs of old females undergo, are accompanied by corresponding changes in their functions. The principal belong to acts which are purely mechanical, and which give rise to what are called the "physical signs" of disease in those organs, and we shall presently see how they correspond exactly with the changes which we have before described as taking place either in the formation of the thorax, or in the structure of the lungs.

CLASS 1.—*Old Females with the Thorax well developed, the Flesh abundant, &c.*

We have already seen that the respiratory organs differ very slightly in this class from the healthy adult; the same is true of the functional acts; respiration is generally performed with ease in these females; deep inspirations are executed without difficulty, though not quite so freely as by an adult; however, the conformation of the thorax already produces some modification in its expansion, which we now proceed to notice. In an adult female, the mean antero-posterior diameter of the chest (taken opposite the middle of the sternum) is from six inches six lines to seven inches; the transverse, at the level of the mammae, from nine inches six lines to ten inches, and near the base of the chest, at the level of the eighth rib, from eight inches four lines to nine inches.

Now, in the old women of the first class here under consideration, we have found the antero-posterior diameter seven to seven inches six lines; the superior transverse 8.6 to 9 inches; the inferior transverse, the same.

result. We do not attach much importance to the absolute length of each of these diameters, but their relative proportion is a circumstance evidently worthy of attention; they express mathematically what has been said in the former paper on the lateral flattening of the thorax in old persons; thus we see the superior transverse diameter becoming as short as the inferior one, and nearly approaching the antero-posterior. As to the augmentation of the diameters during respiration, they take place nearly equally in all directions; but the augmentation is always much less than in the adult, never depressing more than four or five lines. Finally, the sternum, which is projected forwards during inspiration, undergoes the rotatory movement described by Haller in a very feeble degree. The chest of these aged females is sonorous, but not to an exaggerated degree. When the lungs advance, so as to cover the heart, the precordial region then becomes abnormally sonorous, and we sometimes cannot discover a dull sound over the whole left side of the chest. We can see at once how this circumstance is calculated to produce a false diagnosis in diseases of the heart or pericardium, when, for example, this accidental expansion of the pulmonary tissue has become hardened by pneumonia. Auscultation discovers a vesicular respiration, as in the adult, but it is less deep, less abundant, more large and clear.

CLASS 2.—Old Females with a Narrow Chest, and reduced more or less to a state of Senile Extenuation.

In proportion as the organs destined to accomplish the acts of respiration, become as it were worn out, the necessity of performing the function seems to diminish. Frequently the rhythmus of the respiratory movement is excessively irregular and unequal in such females. The thoracic parietes sometimes remain for a long period in a complete state of immobility, and then alternate, with a series of precipitate movements. It is in vain that one would endeavour "to teach them to respire." The attempts which they make to breathe regularly seem only to derange the function in a more marked manner, and instead of inspiring and expiring regularly, we see them perhaps exhausted by violent efforts that lead to no result. In the state of expiration, the antero-posterior diameter is here seven inches to 7.6 lines; the superior transverse is eight to eight inches and a half; the superior transverse seven to seven inches and a half. During a deep inspiration, they can augment the first by five to seven lines; the two last only by one, two, or, at most, three lines. We must also remark, that it often happens in this class that the transverse diameters are an inch shorter than the antero-posterior, and do

not undergo any change whatever during inspiration. Hence we may already draw the conclusion, that in proportion as we advance in age, the powers which dilate the chest, and chiefly those that act on the transverse diameter, diminish considerably in force. Thus, whenever they are able to draw a deep and regular inspiration, we see the thorax elevated all in a mass, carried abruptly upwards, while the first to the last ribs ascend under the skin which covers them. In this manner we have been able to correct, on the living body, the error of Sabatier, who thought the lower ribs were carried downwards, the middle outwards, and the superior upwards. In this general movement of ascension the sternum is raised eight to twelve lines, but it is pushed forwards in a lesser proportion; fixed inferiorly by the depression of the ribs already described, and superiorly by the ossification of the first, or even second, costal cartilage, the rotatory motion of Haller can no longer be executed; nay, in some cases, the movement takes place in an inverse sense, and the projection of the sternum becomes greatest near the superior articulation.

The facility with which the chest is enlarged, either vertically, or from before backwards, is easily explained by what has been said on the persistence of the costo-vertebral articulations in aged persons. In resumé, we may conclude from what precedes, that relatively to the transverse and antero-posterior directions, the play of the chest in the old person is exactly inverse to that observed in the adult; however, there, fortunately, remains a third direction, almost independent of the osseous case; this is the vertical, and hence the diaphragm frequently becomes the principal inspiratory agent; obliged to redouble its efforts, the folds of its surface press forcibly against the posterior edge of the liver, and, doubtless, there form the deep marks before mentioned. How do the respiratory muscles act in the aged person? The space by which the ribs are separated being considerably diminished, the intercostal muscles must lose a portion of their force; however, the other muscles, though weakened by the general emaciation, act freely. We must, in this remark, except the scaleni and sternomastoid muscles, whose direction is changed, and whose power is nearly destroyed, by the change of form which takes place in the upper part of the person during old age. Expiration is sudden and rapid; the chest suddenly returns by one strong effort to its condition before the lungs expand; this act then is performed with more energy than in the adult; but when expiration becomes active, as in coughing, spitting, &c., then the resistance of the thorax overcomes the weakened muscular power.

The changes disclosed by auscultation and percussion in this second class of old per-

sons, are much more remarkable than in the former. The most general and striking is the increased resonance of the chest. In lungs of the third type especially, the sound is as clear as in a person affected with pulmonary emphysema; this circumstance, which might readily lead us astray, if we were not acquainted with it, is naturally explained by the rarefaction of the pulmonary cells, and the dryness and rigidity of the ribs. But the results of percussion are also modified according to the different regions we examine. Thus in front, the part corresponding to the internal moiety of the clavicle, presents only a moderate degree of sonorousness, much less than we find at the anterior-superior region. This fact is precisely the inverse of what was pointed out by Laennec in the adult, and depends, 1st. On the almost constant presence of gray or black indurations at the summit of the lung. 2nd. From the great curve of the clavicle in old persons. On the other hand, from the atrophy of the mammae, it is more sonorous in the region of those organs than in the adult. The sternal region is commonly but little sonorous, from the smallness of the lungs, which do not completely cover the bone, and from the arched form of the latter. It also results from the same disposition, that the heart, more uncovered than it should normally be, gives a sound extremely dull, which corresponds very exactly with its volume. Behind, when the scapulum, in consequence of the inclination of the body forwards, has undergone a movement of rotation, the sound is more obscure in the fossæ of the scapulum than in the adult.

Auscultation.—In old persons of the 2nd and 3rd class (see former memoir), in whom we observe the extreme rarefaction of the pulmonary vesicles, the respiratory murmur varies according as the lung approaches one or other type. In lungs where the vesicles are not yet confounded together, but elongated into an elliptical form, the respiratory sound has lost that full, deep, low character which marks the murmur in the adult person. The bruit is more diffuse; the column of air seems less pressed upon, and appears to enter large spaces. The timbre is also more clear, as if the air struck smaller and more vibrating plates of membrane.

In lungs of the third type, where several cells are confounded together, the respiratory sound is an exaggeration of the one just described; it appears as if it were bronchial throughout the whole chest, only the force and intensity of the bruit are less. Finally, when one lung becomes extensively diseased, as by pneumonia, and the functions of the other are consequently more active, the respiratory murmur acquires more uniformity, and becomes more vesicular. The resonance of the voice is also considerably modified by old age; in many cases it is so great as to resemble a true bronchophony.

In some old women, whose voice is naturally sharp and high, the resonance is occasionally so vibratory and interrupted as to represent a perfect egophony. The bronchophony to which most old people are subject also gives rise to a mucons râle, more or less abundant, which is mixed with the respiratory murmur.

Connection between the Respiration and Pulse in old Persons.—Authors have spoken a good deal on the frequency of the pulse at different ages. Thus, among other observers, Socmmering and Adelon attribute 130 to 140 pulsations to the new-born child; 120 at one year; 110 at two years; 90 at three years; 80 at puberty; 70 in the adult; 60 and less in the old person. In the year 1832, MM. Leuret and Mitivié made some experiments to ascertain how far this supposed retardation of the pulse in old people was conformable to the truth, and they found that the pulse, far from becoming more slow, was, on the contrary, quicker. Their calculations, however, were made on a limited number of individuals, 34 old men, and 41 old women. As to the frequency of respiration in old age, we find nothing certain in authors. It does not appear that any researches have been made to determine with exactness that point. The experiments we made amount to 312; the women were all examined before the act of digestion had commenced, from half past six to half past seven in the morning: of these 312 individuals, 98 belonged to the first class of old persons; 214 to the second; but we were soon obliged to put on one side 57, on account of the irregularity and inequality of their pulse. There remained then 255 females, free from disease, the youngest 60, the oldest 96 years of age.

The addition of their ages gives a total of 18,660; the average being 74.33.

The sum total of the pulsations is 20,984; the average being 82.29.

The sum total of respirations 5558; average 21.79. Hence the relation of the respiration to the pulse is as 1 to 3.41.

1st. Of the 255 healthy women, 83 belonged to the first class, and here we find the following results, viz.,

Addition of ages . . .	6195—Mean 74.64
Ditto pulsations 6673—	Mean 80.42
Ditto respirations 1755—	Mean 21.14

Relation of the respiration to the pulse, 1 to 3.81.

2nd. 172 belonged to the second class; and here we find,

Addition of ages . . .	12,765—Mean 74.21
Ditto pulsations 14,311—	Mean 83.78
Ditto respirations 3,803—	Mean 22.11

Thus we see that both the pulse and respiration are more quick in the second class than in the first. We may draw general conclusions from the numbers just established. In the first place, the average num-

her of pulsations in the 245 women being 82.29, fully confirms the opinion of M. Leuret as to the frequency of the pulse in old persons. It exceeds by 12 the number generally attributed to the adult, and even by 17 the average number found by MM. Leuret and Mitivici amongst the pupils at the Veterinary School at Alfort. On the other hand, if we adopt 20 as the mean number of respirations in the adult, according to M. Magendie, we find the respiration also accelerated in the old person by 1.79. Finally, if we reconsider the division made of old persons into two classes, and compare the results of each, we obtain another curious result, fully confirming what has just been said; we find that in women of the first class, *younger* by constitution than by age, the pulse and respiration are less

frequent than in the second class, who, nearly of the same age (according to years), are more worn down, more decrepid, more *old* in constitution: as to the relation between the pulse and respiration, it always remained the same, i. e., the acceleration was simultaneous and proportioned in both classes.

Again, by analyzing the cases more minutely, and by dividing the whole number into 6 series of from 60 to 140 pulsations, we find that in two-thirds of the old persons the pulse beat at from 70 to 89, and in one-sixth at 90 to 99. It is also curious to examine the progressive augmentation of the pulse and respiration: both these functions augment in frequency together, but the first more rapidly than the second. Let us take an example from the second class.

SERIES.	Number of Individuals.	Mean Age.	Mean of Pulse.	Mean Respiration.	Relation between the Pulse and Respiration.
Below 60 pulsations	1	79	56	24	1 to 2.33
From 60 to 69	21	78.38	64.14	18.58	1 to 3.39
70 to 79	46	74.37	74.37	21.24	1 to 3.50
80 to 89	54	73.09	83.74	22.26	1 to 3.76
90 to 99	29	74.22	94.07	25.24	1 to 3.73
100 to 120	21	73.43	106.52	23.05	1 to 4.79

The constant relation between the respiration and pulse exhibited in the above table is very remarkable; does the same thing occur in cases where the two faculties are disturbed? To answer this question the author had only to recur to fifty-seven cases, which, as we before said, they were compelled to separate on account of the irregularities they presented; of these fifty-seven, fifteen belonged to the first class and forty-two to the second:—

The mean age of the women was .. 66.50.
 Mean pulse 75.17.
 Mean respiration 27.75.

Hence the relation of the respiration to the pulse is as 1 to 3.71; but as, in the two classes united, the numbers were as 1 to 3.41, we have a difference of 0.31 furnished by the fifty-seven cases.

The experiments from which the above calculations were drawn have been performed with the greatest care, and a desire to avoid every source of error; the observations, moreover, were made on females *all* placed exactly in the same conditions of health, situation, nourishment, &c. &c.

It remains to say a few words on the difference between the numbers now given,

and those derived from the observations of MM. Leuret and Mitivici at the old hospitals.

The thirty-four women examined at *Salpêtrière* gave a mean pulse of 79, instead of 82.19, which results from the experiments of our authors. However, we should remark that the pulse of the patients examined by M. Lebut never passed 100, while that of M. Hourman varied from 80 to 144. Again, of the forty-one old men examined at Bicêtre, fourteen coughed; there remain then twenty-seven, who give a mean of seventy-four exactly. The same number our authors found in separating all the extreme pulsations, and it is curious to observe that M. Lebut declares he did not venture to comprise in his tables a certain number of old persons, although they appeared perfectly healthy, because the pulse presented a frequency which seemed to him incompatible with good health. How easily is the most accurate observer led astray when he allows a preconceived idea to turn him aside from the facts which are before his eyes!

ANOMALOUS CASE OF LITHOTOMY.

REMARKABLE DILATATION OF THE LEFT CAPSULE OF THE PROSTATE.

To the Editor of THE LANCET,

SIR,—If you deem the accompanying case worthy of admission into your valuable periodical, its insertion will much oblige, Sir, your most obedient servant,

JOHN LIZARS.

38, York Place, Edinburgh;

Jan. 22, 1836.

A surgeon attached to a large hospital has peculiar opportunities for improvement, and he fails in his duty if he either neglect them, or conceal the useful results of his observation and experience. Success, though it flatters vanity, is at best an equivocal proof of merit, for it may happen to the rash and unskilful. Successful cases, in ordinary circumstances, when published, afford but little information; cowardice may be unwilling to divulge the unsuccessful, but these are for the most part our proper instructors; from these we learn whether nature or art is the more to be blamed for any untoward event; but whether successful or unsuccessful, those cases are invaluable which lead to the detection of such morbid deviations as would certainly occasion the death of a patient in the hands of a timid or irresolute operator. Of this last class is the following:—

CASE.—James Brown, a healthy-looking man, fifty-nine years of age, entered the hospital on the 29th of December last, and presented the usual symptoms of stone in the urinary bladder, under which he had laboured during the last eight months. He was in this hospital seven months ago under the late Professor Turner, who sounded him, but detected no calculus. The day after his admission he was carefully sounded, but no stone was felt; the bladder was rough and fasciculated. He was ordered warm-baths, leeches to the region of the pubes, the *mistura aqua polacis*, the *ura ursi*, and a seton over the pubes. All irritation having been subdued by these means, he was again sounded, and a stone distinctly perceived. A dose of castor oil was administered, and on the following day the lateral operation was performed.

Operation.—All the preliminary steps having been taken, and the existence of a calculus again ascertained, a large staff was inserted, which could not be made to pass the prostatic portion of the canal. A smaller staff was next employed, which apparently entered the bladder, as its handle was loose and moveable. One of my colleagues held it over the pubes, whilst I commenced and

cut down to the membranous portion of the urethra. I then proceeded, seemingly through the left lobe of the prostate gland, which was hard, cartilaginous, and studded with calcareous depositions. The left forefinger, which guided the lithotomy knife, seemed to enter the urinary bladder, and a little fluid, considered to be urine, flowed out, when I begged the staff to be withdrawn. I next inserted a pair of forceps; but instead of a calculus, such as the sounding had led me to expect, I discovered nothing but calculi, varying in size from that of a millet seed to that of a pea. I now used a searcher, but was not more fortunate. My finger felt a pouch, equal in magnitude to a urinary bladder, which contained numerous small calculi. One of my colleagues, at my request, introduced his finger, and the sensation communicated so nearly resembled that of a mucous membrane, that he suspected I had wounded the rectum, but convinced himself of the contrary by examining that viscous with the forefinger of his other hand. Another of my colleagues was also requested to examine, and he, with a scoop, removed some of the small calculi already mentioned.

I now inserted a catheter, which passed the entrance of this pouch, and got into the bladder, and urine flowed out. The catheter was replaced by a staff, along which the knife was carried through the neck of the bladder, as there was no substance like prostate gland, and a stone of the size of a flattened plum was instantly extracted.

The first incisions into the pouch occupied about one minute; the second incision, and the extraction of the calculus, about another minute. From fifteen to twenty minutes were spent in examining this pouch.

The patient has had no bad symptom—no case of lithotomy ever went on more favourably, and this is now the tenth day from the operation.

Remarks.—The anomalous pouch, which rendered this case so complex, seems to me to have been nothing more than the external fibrous capsule of the left lobe of the prostate gland gradually dilated until it became as large as the bladder itself.

Crosse, in his work on Urinary Calculus, p. 34, says, "Concretions in the prostate gland, commencing in its ducts, often at a distance from their urethral orifice, even at the very bottom of a duct, go on increasing until each duct is enlarged into a pouch, rendering an escape of the concretion into the urethra impossible; the narrow orifice by which the pouch communicates with the urethra often becomes closed in consequence of inflammation and effusion of lymph; the pouch is a secreting cavity, which furnishes additional deposit; and as the concretions enlarge or multiply, the pouch enlarges in the direction where there is least resistance,

towards the lateral or posterior surface of the prostate gland."—See plates ix, fig. 1, and xi, figs. 2 and 3.

Wilson, on the Urinary Organs, at page 353, also observes, "I have met with a urinary calculus larger than a common-sized olive, in a cavity of the prostate gland, where, from the orifice which first admitted it, having contracted, or the size of the calculus having enlarged the stone could not be pressed back into the urethra, and the whole of the prostate gland had been changed into a capsule surrounding it."

I possess a preparation in my museum with cysts exterior to the urinary bladder, one of which may hold from four to five ounces. These communicate with the bladder. I have also another preparation, where the right lobe of the prostate gland forms one capsule.

I freely confess that I was not prepared for the complication just described, nor am I ashamed to confess it, since no mention is made of such an anomaly in the writings of the most eminent surgeons, if we except Crosse and Wilson, from whose works I have quoted above, but which I had not seen.

POOR-LAW MEDICAL CONTRACTS.

STATEMENT OF PROCEEDINGS AT THE
WHEATENHURST UNION,
GLOUCESTERSHIRE.

To the Editor of THE LANCET.

SIR,—I consider it a duty which I owe to myself and my professional brethren, to forward to you what information I possess on the subject of the Poor-law Union contracts. An Union called the "Wheatenhurst Union," in the county of Gloucester, is just formed in my neighbourhood, and I am the only surgeon residing within the Union which comprises 14 parishes, containing a population of nearly 8000 inhabitants. I have attended nine out of the fourteen parishes for nearly eighteen years, and have great pleasure in stating that I am much respected by every class of persons, and what is more, I have professionally attended the poor in a manner which has given them entire satisfaction; I believe there is not a pauper in either of the parishes who would not serve me in any way he could. This of course is self-praise, but I state it simply to make you fully acquainted with my case.

When the Union was first formed, I attended, by invitation, as a parishoner, was introduced to the deputy Commissioner (Mr. Weale), and then stated to the Magi-

strates that I should offer myself as a candidate for the appointment of surgeon to the Union; and as I could not possibly fulfil the duties of the whole Union, I would divide it with a gentleman, Mr. Holbrow, surgeon, of Stourhouse, who lived within an easy distance of ~~the~~ ^{the} and who had ~~been~~ ^{been} one of the largest ~~of the~~ ^{of the} and ~~with~~ ^{with} to himself and entire satisfaction to his employers and the poor. On the evening before the day for electing the officers, I wrote to a friend and patient, a magistrate, to request he would propose me as surgeon to the Union, in conjunction with Mr. Holbrow; in answer to my note, he politely stated that he did not think I could divide the Union as I proposed, but that it would be divided into two districts on the morrow; that probably advertisements for tenders would be made in the papers, and that I had better wait and see what was done, adding, that he would take care and mention my name. In answer I begged to assure him that if such was the case, and the lowest tender was to be taken, both myself and Mr. Holbrow would decline offering ourselves.

In consequence of this, when the business came on, my friend asked if it was necessary that tenders should be advertised for, and if so, if the lowest would be accepted. The deputy immediately said that it was their usual plan; that he knew medical men objected to it, but that they always "came to." Accordingly the usual form of advertisement appeared in the county papers, and I was informed that the Union would not be divided in any other way than was announced, which was most inconvenient to us as surgeons. We therefore entered into articles of partnership, to obviate this difficulty, and then no objection could be made to the signatures to the returns.

I again wrote to my friend requesting that he would propose us as surgeons to the whole Union at a salary of 150 guineas per year, and 1*l.* for each midwifery case. There were two other tenders, the one 140*l.* for the whole, and 1*l.* for each midwifery case, the other 40*l.* for district No. 1, and half-a-guinea for each midwifery case. The gentlemen who made these offers, lived at so great a distance, that very little attention was paid to them, and I am given to understand that seventeen out of twenty of the Guardians were favourable to our election. Before, however, anything could be said, Mr. Weale got up, and stated that the salary was much higher than he could sanction, and if we were appointed, the Commissioners would not confirm our appointment; that it would be much better to have a talented young man "*from the hospitals*," for "*what could country surgeons know?*" and that the salary should be fixed at 100*l.*, including everything except midwifery, which should be fixed at 10*s.* 6*d.* per

case. The Union is fourteen miles broad, and contains 2500 paupers to be attended by the surgeon. Advertisements were again published in the country papers, and in *THE LANCET* (vide Number for Oct. 17), when Mr. Wootton said that he should have fifty applications. The Wednesday following he was again appointed to the Union, when only one tender arrived, offering to undertake the duties of the appointment, without making one inquiry as to the extent of country, or the numbers of the poor. This person's name is Mr. FRANCIS XAVIER MOSELY, a gentleman who has practised somewhere in America. The whole ground-work of their choice was simply his public testimonials, no one knowing whence he cometh, or whither he goeth; and as this adventurer could not immediately become resident, I was requested to take care of my part of the Union, nine parishes, until Mr. Mosely arrived. This, sir, of course, I did without fee or reward, for upwards of a fortnight. The gentleman has now been here more than a month. *He has no instruments.* I lent him a catheter only a few days ago. He has no horse, nor any means of conveyance whatever, but his legs, to visit his patients. The sick are very numerous, and I have no hesitation in saying that *no man, with two of the best horses in the world, could perform the duties he has engaged to perform*; I can assure you, Sir, that I would not accept the whole Union at an equivalent salary, because I feel that I could not do my duty towards the afflicted poor, which hitherto I have ever done.

Now, Sir, I have stated the situation in which our poor are left. I am constantly harassed by their applications to me for medical relief, and how I am to act I cannot tell. I should state that the professional men in this neighbourhood are tolerably well educated, and I was myself early in attendance on hospital practice in Bath, and filled the office of house-surgeon to *St. Bartholomew's Hospital* in the year 1812. I have performed most of the operations in surgery successfully, and, amongst them, several in cases of aneurysm. I merely mention this to show, that my claim rested upon a good foundation. I have resided here nearly twenty years.

I beg that you will make use of this letter in any way you think proper, and I shall be happy to give you further information if required. The price per head, I should have stated above, is 9¹/_d. per year.

I am, Sir,
Your obedient servant,
THOMAS WATTS.

Frampton-upon-Severn, near Stroud,
Gloucestershire, Jan. 1838.

RATES OF ATTENDANCE ON THE SICK POOR.

To the Editor of *THE LANCET*.

SIR,—Your remarks respecting the poor-law medical contract system, in *THE LANCET* of the 12th ult., escaped my perusal until within the last day or two, and observing the earnestness with which you urge the necessity for proposing some plan before the meeting of Parliament, which may tend to supersede the arbitrary, unjust, and cruel measures now adopting by the guardians of Unions, under the sanction of the Poor-Law Commissioners and Assistants, I again trouble you on the subject. The circumstances attending the position of myself and other professional gentlemen in this district, as regards the Union, are fully stated in the petition I forwarded to you on the 18th of September last. In the arrangements that may be made, a specified rate of charge per head, on the gross population of each parish, according to the last census, would be the most desirable mode (if fixed at a fair ratio) of obtaining equivalent remuneration for medical and surgical assistance to the poor. Accordingly, I have made below a calculation of the average expense per head, for the last seven years, for medical attendance on the poor of eleven parishes, attended by me for twenty-five or thirty years past. Some of the parishes are contracted for, and others are attended at so much per case, journeys as well as medicines being charged with a liberal consideration towards the rate-payers, and in no instance has the expense been complained of as greater than was just for the services rendered; and on consulting my medical brethren, it appears that the average as nearly as possible corresponds with theirs.

In *THE LANCET* for the 5th of December, in which you have stated that the expense for medical and surgical attendance on the criminals in the Penitentiary amounts to 1¹/_d. per head per annum, you have also stated that the labourers in the Unions are provided with similar attendance at the rate of from 2s. to 3s. 6^d. per head per annum; but I may I think with correctness assert, that in no instance where Unions are contracted for, does the rate of remuneration amount to one-half of either sum; and as the precise sum offered by the guardians of the Docking Union was not stated in the petition before-mentioned, I now beg to inform you that the population of the combined parishes is 15,368 persons, full four-fifths of whom are agricultural poor, 200^l. or about 3^d. per head per annum, being the amount offered for medical and surgical attendance and medicines, operations, midwifery, and trusses for hernia.

There is considered one circumstance also which I claim, to be in any application to Parliament, the arbitrariness, particularly noticed, and that at the instance in which guardians, etc., stop often of assistant-commissioners, the large proportion of the estate of the holder's income, which perhaps twenty shillings supports his family, after industry. Thus, in parishes, where, he in a division marked out by the Board as a western division, and the person who for many years has been the attendant of such parishes, happens to reside on the eastern side of the line, those parishes are unceremoniously assigned to another practitioner who happens to contract for the western division, thus depriving the original attendant not only of his parish attendance, but, necessarily, of a large portion of his casual private practice, owing to his not visiting such parishes so frequently as when in attendance on the poor; and this is done merely in order that the relieving officer may receive certificates of the health of paupers, from the surgeon of his division, although the fact that no inconvenience can arise from the circumstance of the medical man and the relieving officer residing in different divisions, is proved, by the regularity and facility with which certificates have been forwarded, notwithstanding the various parishes have as yet continued to be attended by the original medical practitioners, owing to medical officers not having yet been appointed, partly by reason of their refusal to comply with the terms offered, and partly from the existence of private contracts with the different parishes not terminating until Lady-day next. I am, Sir, most respectfully, your obedient humble servant,

EDWARD MANBY.

East Rudham, Norfolk, Jan. 20, 1836.

The following is the table above mentioned. The contract in the first seven is for medical attendance, cases of surgery and midwifery being charged for exclusively, but included in the average sum stated per head. East Rudham is six miles distant. Nos. 8, 9, 10, and 11, are attended, per case, at the sums stated per head.

	Average per head.	
	s.	d.
1. East Rudham	0	7½
2. West Rudham	0	8½
3. Harpley	0	8½
4. East Rudham	1	7
5. Houghton	1	2
6. Bircham, Great	0	3
7. Bircham Tofa	0	11½
8. Syderstone	0	8
9. Gatesend	1	11½
10. Banner	1	11
11. Dagthorpe	1	3½

ANNUAL ELECTIONS

AT THE

COLLEGE OF SURGEONS IN IRELAND.

The Editor of THE LANCET.

SIR,—The fidelity with which you, from time to time, give publicity to the political affairs of the Royal College of Surgeons in Ireland, encourages me to trespass on your valuable columns with a brief statement of the proceedings of this extraordinary corporation on "Hansel Monday."

That being the day fixed by charter for the election of officers for the ensuing year, the Tory party, of black-balling notoriety, mustered all their forces, in anticipation of strong opposition from the reformers. But what, think you, must have been their astonishment when the hour of contest, one o'clock, had arrived, without a single member of *genuine* reform principles having appeared in the board-room, the supposed arena of party conflict! No, not a Peter-street, nor a Richmond-man, nor a liberal from any quarter, was to be seen on that eventful occasion! It may be asked whence the cause of this apathy? Have not all members of the corporation an equal interest in its prosperity, and are they not all equally bound to maintain its stability? Nothing can be more fair, nothing more rational, than that such a question should arise in the minds of impartial persons at a distance, who are but little acquainted with the internal workings and perpetual intriguing of the predominant party in this immaculate body; but in the estimation of those who are well informed on the subject of College politics, the liberal party must stand acquitted of any neglect of duty, on the score of absence, on the present occasion. They have, over and over again, endeavoured to assert their rights and establish liberal measures, with a view to keep pace with the spirit of the age, and thereby maintain the respectability of the profession; but no sooner were the doctrines of liberality and fair play sought to be introduced into the proceedings of the College, than that ever-fertile note of dissension, in this unfortunate country,—that tocsin of discord,—“the No-Popery cry,”—was sent forth by that imp of bigotry and intolerance—JACOB, who, in accordance with the enlightened views of his worthy coadjutor in intrigue, CUSAOK, resolved on a plan for black-balling every candidate for membership, who might be suspected of entertaining either liberal opinions or just views of passing events. The machinations of those narrow-minded individuals, however ill-judged or base they may appear to men of honest views, have, nevertheless, so far

MISSTATEMENTS RESPECTING ARTICLES

succeeded in converting the College into a species of *private or party property*, that any efforts from the most active band of reformers to preserve the corporation from total and deserved subversion would prove unavailing. They have tried the experiment of *remoteness* have become the seeds of bigotry to be uprooted by "the fairer, less men," who have been left to fight the battle of independence. They now rely, with confidence, on the exertions of Mr. Warburton, for the final settlement of a question with which he is so well acquainted.

Well, Sir, "the loaves and fishes" of place and corporate honours were quietly left to the disposal of the monopolists, who, I need scarcely tell you, acted most generously towards themselves. Out of twenty-two officers who were elected, there is not one before whose name a conscientious man would venture to prefix the significant adjective *independent*; and, with two exceptions, their "honours" cannot, in any station of society lay claim even to a character for excessive respectability. By way of elucidation, I beg to apprise you that a Mr. Frank White is the new President, and a more fitting personage could not possibly be placed at the head of such a corporation! He is endowed with the convenient powers of the chameleon, and adapts himself to circumstances, by assuming for the time being the political hue of any party which may be rendered available to his own personal interest. In accordance with this judicious rule of acting, he is, in collegiate affairs, a boisterous supporter of every monopoly and abuse which selfishness can suggest; whilst at parochial meetings he deems it expedient to play the part of the poor man's advocate, and in this way attract attention, thinking that he excites the admiration, of the humane part of the community. As a general politician, he *says* he is a reformer, and, in confirmation of this assertion, he stated to the liberal Chairman of the Parliamentary Medical Committee that he had been most unjustly excluded from the Surgeoncy of *Steven's Hospital*, solely on the grounds of his being a Roman Catholic. However, not having much confidence in his own word, on a very recent occasion, he felt it necessary, when putting forward his claims, supplications, and lamentations, to the present Government, as a candidate for the situation of surgeon to the *Richmond Hospital*, to transmit to his Excellency Lord Mulgrave, an *affidavit* confirmatory of the truth of his original statement to Mr. Warburton! I wonder what does his Protestant brother, the Town-Major, think of this line of proceeding,—he who was converted at the "altar of Hymen," on the faith of the late Dr. Blake's money, from the errors of Popery; and, at the same

blissful moment, embraced *purse*, and Thirty-nine Articles!

"Quid non mortalia peccata,
Auri sacra fames!"

Lord Haddington had, I am, no idea that the incessant follower of his Government, Surgeon, had suffered so much temporal punishment for his superstitious adhesion to the doctrines of the Church of Rome! Oh! religion, how much is thy sacred name abused!

And who is the Vice-President for the ensuing year? No less a personage than Mr. WHITE's congenial partner and co-operator in College affairs—THE REDOUBTED ARTHUR JACOB! Yes, Sir, such is the almost incredible fact. WHITE and JACOB are really the President and Vice-President of the Royal College of Surgeons in Ireland! *Arcadis ambo!*

"Ah! sure a pair was never seen
So justly formed to meet by nature."

I forget the next line, but *quis istos separat*. JACOB, the vulgar buffoon, whose discursive and disgusting harangues are composed of gleanings from the fishwoman's vocabulary, and the resurrection-man's glossary,—he who is the avowed advocate of black-balling bigotry and monopoly,—the Conservative champion of every corporate abuse,—he who made such an exhibition before the Parliamentary Medical Committee; and yet, on a late occasion (acting on the supposition, no doubt, that the evidence given by the Irish witnesses would never be published), had the effrontery to state at a public meeting of the College of Surgeons, that he was "the man who told the arch-reformer, Warburton, to his teeth, the absurdity of his attempting to put down or interfere with the Irish College of Surgeons,"—such is the individual who has been elected Vice-President of this once respectable body, which is now dying a natural but a most ignominious death. I remain, Sir, your most obedient servant,

OBSERVER SECUNDUS.

Dublin, January 15, 1836.

LATE ELECTION AT THE RICHMOND HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

SIR,—It is much to be regretted that such an illiberal religio-political tone, as has of late distinguished more or less many of your Irish articles, should have found its way into the pages of THE LANCET: this can never have been intended by the Editor, whose exertions, I am convinced, are honestly directed towards general improvement, general utility, and the interests of science. Such

a temper may gratify, as it would appear to be the result of, sectarian bigotry, but it holds no kindred with the better feelings of the majority of the profession. It proceeds from a ungenerous and uncandid minority, distorting facts, in order falsely to enlist public feeling on their side, and forward their own selfish interests and bigoted sentiments, without regard to the evils which will undoubtedly ensue from the proceedings, viz.:—1. The splitting of the reform party; the Protestant portion of which cannot be expected to co-operate with those, who, under the mask of medical reform, would advance the interests of political-religious fanaticism; and 2ndly. The creation in good earnest of similar feelings in the opposite party, which, I am happy to say, have at present their chief seat only in the jealous and excited fancy of your correspondent. Why introduce into a medical journal at all, the exciting subjects of politics and religion? Most urgent indeed should be the occasion to justify such proceedings. Surely the medical profession at least should be the happy neutral ground, where men of science and philanthropy (though belonging to all sects and parties) might meet on equal terms, free from the rancour of those distracting topics. The medical profession is not, nor should it be, political: the terms religion or politics should never be heard in the pursuit of medical science, or the distribution of its honours; and he is but an ill friend to the profession or to science, who will persist in flinging this apple of discord among the members of the one or the cultivators of the other.

It may be quite true that the majority of medical appointments (such as they are, and God knows they are few and shabby enough) is held by Protestants; but it is to be remembered, that until of late years, there were very few of any other persuasion in the medical profession (and even still they form a vast majority), while the patronage was vested in persons of the same creed, they forming the bulk of the respectable classes and the *subscribers*,—subscriptions very generally conferring proportional influence. Thus what is selfishly objected to by a few, for reasons easily divined, followed naturally from the condition of things, without any party malevolence or exclusive bigotry whatever, which in truth were never expressed or felt.

Nor is the profession at this day conducted in that hostile feeling your correspondent imputes (unless indeed the exertions of any and the party to which he belongs shall engender it). Individuals of course there are, who are as bigoted as the most infuriate Tory or Radical could desire, but neither the College of Physicians nor the College of Surgeons, as a body, enter into any such sentiments. The latter, from having no connection with the University, is more es-

pecially free from politics and religion, and it is its boast, that, as a body, it has never taken any step in the spirit of either. The fact is, the party who in that body exercise such a pernicious influence, and have metamorphosed a public institution into a private school job, are seated in the same way at the public expense, to the exclusion of every one else, prefer money to religion or politics either; and they look only to the medical reform sentiments of those they wish to promote: thus their president and several others of the officers are at this moment Roman Catholics, and some of the hottest College partisans belong to the same creed, while the claims of Protestants are disregarded, because they are reformers. So little does religion or politics prevail among the thick-and-thin "College men," that the Chief among them, Cusack, Jacob, and Harrison, have alternately figured as Conservatives, Liberals, and Radicals, and at this moment the public neither knew, nor perhaps care, in which corps to class them.

Why then object in such unmeasured terms to the recent government appointments to the *Richmond Hospital*? Oh, but Mr. Adams is a Tory! He never gave any evidence of any such sentiments. All that the public can know, or indeed is to be known, on the subject, is, that he *professes* the established religion; and is this to be a bar against all promotion? Truly this is one-sided liberality with a vengeance!—I do not wish to be the vindicator of Lord Mulgrave's Government, but I must say that all but prejudiced bigots must see, that in this case, at least, he acted properly, not only for the advantage of science and the Institution in question, but also for the interests of that party which gives such obliquity to the optics of "*Observer*." 1st. It would be easy, but not very gracious, to demonstrate not only that Mr. Adams was by far the fittest person in "*Observer's*" list, for the vacant office, but that none of the others were actually adapted for the position they had the impudence to claim. And, 2ndly, By the promotion of Mr. Adams, two appointments were vacated; one of which was at once conferred on Mr. Cholera White, an ultra Roman Catholic,—and the other, "surgeoncy to the *Jervis-street Infirmary*, which leaves an appointment for another Roman Catholic in that Institution. I say nothing of the appointment of Mr. M'Donnell, as I presume that he cannot be objected to, inasmuch as his sentiments are as much opposed to an established religion, and his politics are as extreme as those of any Radical of them all. Further than that, Mr. Carmichael could not have had any "jobbing understanding" with him, as the appointment was made out while Mr. M'Donnell was in Paris. I may also add, that the arrangement did not originate from the Commissioners; they were merely consulted as to the propriety of the

effects than by any agent with which we are acquainted. We scarcely, in fact, yet know any of the uses of electricity. The only use of the magnet we know is its pointing to the north; and with voltaic electricity we merely produce sparks, and only very rarely. The philosopher should try

to discover the uses of electricity in, or otherwise. Respecting the apparatus I have got here, those who choose are at liberty to try its effects. The shock to be given depends very much on the length of the wire which may be employed. With a short wire the spark will be pretty bright, but productive of scarcely any physiological effect. With a very long wire the spark will be exceedingly feeble, and the physiological effect very powerful. With regard to the subject immediately under discussion, I can only say that, as we are all engaged in the same great search for truth, if in any respect I can be shown to be wrong, I will most willingly adopt more correct views. It is only within the last three years, for instance, and since I came to the *London University*, that I was satisfied that particles of light did not come from the sun. No imputation can justly fall upon us for correcting our views. I wish we could treat political questions upon the same principle, so that the ordinary and domestic affairs of life might not be interfered with by our notions on those subjects, and that a man, when he obtained more correct views of political questions, might adopt them without being subjected to the reproach of being a "turncoat." If the discussion here is sufficient to induce medical men to turn more of their attention to the important subject debated, I shall rejoice at having helped to add to the interest of a science, which, I assure you, I have most warmly at heart. (Much applause followed the remarks of the learned professor as he resumed his seat.)

Dr. SCHMIDT said that, until he adopted his present views of magnetism, he had entertained those explained by Dr. Ritchie. Dr. Schmidt then explained some of his views in answer to those of Dr. Ritchie which we have not reported, and the whole of which, therefore, we omit, — with less regret, indeed, from the circumstance, that they would not form a useful portion of a medical report. He asked, however, why Dr. Ritchie said that we, as yet, knew but very little of electricity and magnetism, and yet argued that it was impossible that magnetism should produce any physiological effects. Opportunity, he (Dr. S.) thought, was only wanted to follow out ideas on the subject. He was only desirous of having the merits of the magnet tried as a remedial agent. If Dr. Ritchie would at any time do him the favour of joining him in an examination into all the circumstances of the production and power of his magnets, he would be most happy to adopt Dr. R.'s views, and

publicly acknowledge his error, provided ground were shown to him for the change.

Dr. RITCHIE said that he considered this with one or two very slight exceptions. Dr. Schmidt and himself after all entertained nearly the same opinions. Dr. Schmidt had certainly stated nothing that was not before very well known. He should be happy, at the next meeting, to meet him, to explain and hear explanations, and to afford him the use of all his apparatus at the University; and if he (Dr. S.) could convince him (Dr. R.) in the end that he was wrong upon any one point, he would most readily acknowledge it.

Mr. BIRD stated that he had tried various experiments upon the human body with an electro-magnet which he possessed, but that all his experiments produced the same results, whether the electro-magnet was connected with the battery or not.

The thanks of the Society were then presented, by a general vote, to Dr. Ritchie for his attendance this evening, and for the very lucid, able, and highly satisfactory statement he had made. On a suggestion that "both the experimentalists should be included in the vote," the President observed that there was a rule of the Society which prevented this course being pursued with respect to any of its own members, and that Dr. Schmidt had been admitted a member that night. The Society was then adjourned.

NORTH-LONDON HOSPITAL.

THE first annual report of this establishment has just been issued. The hospital was opened for the reception of patients on the 1st of November 1831, and the books show from that time up to November 1st, 1833, the following list:—In-patients admitted, 1156; out-patients, 1299; casualties relieved, 1664; lying-in women attended at their own habitations, 270; total 3789.

The patients who have died in the hospital during the year amount to 90; in-patients remaining at the date of the report, 123. The hospital now contains 130 beds. A loan of 2500*l.* has supplied the deficiency in the sums required to defray the whole cost of the present building and outfit, which amounted to 7670*l.*, of which sum 5170*l.* were raised by subscriptions. The Committee propose to liquidate the debt and enlarge the hospital by establishing a building fund, a foundation for which has been made by Mr. Henry Philip Hope, of Connaught place; who, in addition to other donations, has placed at the disposal of the Committee the sum of 200*l.* for this purpose.

Although the ordinary expenditure of the first year has been greater than will be in

future required to support the hospital in its present extent, yet the receipts arising from the fees paid by students (devoted by the medical officers to the support of the patients), and the contributions at the Anniversary Dinner in May last, have been such as to leave a small balance on the twelve-months, in the hands of the treasurer. The following are condensed statements of the accounts:—

Receipts and Expenditure from June 1832 to October 31, 1834.

	£	s.	d.
Donations and Collections at Churches	4366	11	6
Profits of a Bazaar in the Regent's Park, in June 1834	502	3	0
Dividend on Consols	1	12	9
Donation for Investment, by W. L. D.	100	0	0
Queen Caroline Fund	1200	0	0
	£ 6170	7	3

	£	s.	d.
Paid to Builders and Architect	5176	3	9
Salaries and Wages	307	15	8
Advertisements, Printing, Stationery, Postage, Portage, Incidental charges, &c.	365	19	8
Investment in 3 per cent. Cons.	100	0	0
Balance in Treasurer's hands	280	8	2
	£ 6170	7	3

Receipts and Expenditure from Oct. 31, 1834, to Oct. 31, 1835.

	£	s.	d.
Balance in hand	280	8	2
Loan at 4½ per cent.	2500	0	0
Fund raised for the projected Eastern Fever Hospital, transferred by Donors	52	10	0
Collection at Church	65	0	0
Bequest of Colonel Sackville ..	31	10	0
A Third of the Profits derived from the Colosseum Fete ..	188	0	0
A second Donation for Investment, by W. L. D.	100	0	0
Dividends on Consols	4	17	11
Donations, Collections, &c.	1991	13	3
Annual Subscriptions	256	3	0
Fees paid by Students for attending the Practice during the Session 1834-35	3130	1	0
	£ 8600	3	4

	£	s.	d.
Balance paid to Builders	2677	17	5
Furniture, Fittings, & Repairs ..	1841	3	0
Pharmaceutical Fittings and Apparatus	69	4	2
Surgical Instruments, Splints, &c.	131	8	0

Advertisements, Printing, Stationery, Case-Books, Postage, Portage, &c. &c.	284	12	0½
Meat, Bread, Milk, Groceries, Rice, Meal, Stores, Vegetables, Cheese, Candles, Soap, &c.	1278	13
Coal and Wood	215	5	11
Wine and Spirits	64	15	10
Beer and Porter	148	7	2½
Patients' extra Diets	33	6	0
Bandages, Linen, &c.	49	7	1
Washing	179	2	5
Incidental charges	84	0	1
Salaries, Wages, &c.	674	14	5
Drugs, Lint, Tow, Plaster, &c.	447	18	4
Spirits of Wine	29	5	9
Leeches	32	0	0
Burial Expenses, Insurance, Water Rates, Gas	28	8	6
Guarantee to R. Liston, Esq.	156	10	0
Interest on Loan	56	5	0
Investment in 3 per cent. Cons.	100	0	0
Balance in Treasurer's hands ..	17	8	3
	£ 8600	3	4

To the Editor of THE LANCET.

SIR,—Dr. Macleod having repeatedly libelled Dr. Cummin, a lecturer at the Aldersgate-Street School of Medicine, by giving circulation to a report that Dr. Cummin was the assistant editor of the *Medical Gazette*, it was resolved by some of the students of the school to inquire of Dr. Cummin, after his lecture on Wednesday last, whether that statement was true. The design was accordingly carried into execution on that occasion, the impression being very strong, that neither the slanderer of the students at their late meeting, nor any person so intimately connected with the slanderer, ought to continue any longer secret in the person of Dr. Cummin, if the libel were true. It is but justice to Dr. Cummin to make known in your Journal, that his reply to the questions put to him on Wednesday was, that he neither was the author of the slanderous article, nor could have prevented its insertion in the periodical in question, nor was connected in any way, directly or indirectly, with the editing, the management, or the production of the *Medical Gazette*. I am, Sir, your obedient servant,

AN ATTENDANT AT THE ALDERSGATE-STREET SCHOOL.

Jan. 27, 1836.

CORRESPONDENTS.

To the Editor.—SIR,—In your report of the proceedings of the Meeting which took place at the Crown and Anchor on Monday evening the 18th of January, a short speech is attributed to "Dr. BLUNDELL." Will you allow me to state, that as I

was not present on that occasion, the address in question was not spoken by me. I have the honour to be, Sir, your obedient servant,

THOMAS LEIGH BLUNDELL.

20, Lombard-street, Jan. 23, 1836.

A Hospital Pupil, Glasgow, must be more explicit before publishing any statement on the subject, we must have the names of the offenders and the aggrieved; the letter must be confidentially authenticated.

However widely the medical gentlemen have differed, they must all have denied the truth of the impressions stated in *Gamma's* letter. The details described therein were not "new," but impossible. We can express no other opinion on the case than that already given; and the treatment can be directed with propriety only after a personal interview with any medical gentleman who may undertake to prescribe for the afflicted patient.

Mr. Matthews.—The wax model was a section of the skull, showing the ganglion oticum, with its branches, and the tympanum, published by Mr. Schloss.

We shall feel much indebted to any of our readers who will take the trouble to inform us, by letter (addressed personally to the Editor), of the names and places of residence of such medical men as they know to occupy the office of Coroner in any part of these kingdoms, whether for towns or counties, and whether living near to, or at a distance from, our correspondents, with the dates (or not) of their appointment.

Does Mr. Brookes desire that his letter should be published? Of course we cannot undertake to call upon the three parties whom Mr. Brookes has named. The bare reference to those parties proves the truth and accuracy of our brief critical notice. If the statements in the book be satisfactory, whence the necessity for the collateral aid? We have examined the work again, and are now ashamed of the lenity of our first notice. If we have acted unjustly, it certainly is not to Mr. Brookes, but to the profession and the public. If Mr. B. is not contented, we shall have much more to say on the subject; but we hope the book is shelved.

The letter respecting the Dorsetshire Medical Association, would be charged as an advertisement at the Stamp Office. A passage from it, however, showing the objects of the Institution, will be inserted in the next week's LANCET.

The particulars of the meetings at St. Thomas's Hospital and the London University have been laid before us. At the one, nine students in thirty-four, and at the other seven students in four hundred, have put their hands to documents declaring that the Apothecaries' Company is the pink of British medical institutions. The St. Thomas's students are said to have declared the same thing in writing at King's College, pro-

vious to their sail down the Strand to the Borough.

The facts stated by *Investigator* shall be published, but it is impossible to find a place for them this week.

It would be better to lay the plan for the "Student's Association," which has been sent to us, before a meeting of the gentlemen who are interested in its adoption or rejection. The sanction of our correspondent may therefore be obtained from the publisher.

The report from the Royal Institution will appear next week.

R. R., Jewin-street.—Time fails us for an epistle. Unless the want is urgent, it would be both economy and good policy to wait.

Mr. Bateman.—1. No farther portion has yet been issued. When it appears, our analysis and comments may be resumed.—2. The means of conclusion have not yet been afforded us by the only party who can supply them.—3. Most probably they will.

Mr. Baxter's case has reached us.

The letters of Mr. H. Prater, Mr. Samuel, Mr. Erett, Dr. Kelsa, Dr. Wm. Ferguson, George F. (part), A Pupil of the Borough Hospitals, A Member of the Royal College of Surgeons (part), Anti-Humbug (part), A King's College Medical Student, A Licentiate of the Apothecaries' Company, and H., are intended for insertion.

We have received a letter from Mr. Meade, the Chairman of the late meeting at the Crown and Anchor Tavern, stating that several untruths appeared respecting him in Dr. Macleod's journal of last week. The space which would be occupied by Mr. Meade's letter in our columns, would be ill-bestowed on the fabricator of Messrs. Longman's periodical; and we therefore hope that Mr. M. will be satisfied with the above statement relative to its contents.

The report from St. George's is necessarily postponed for a week.

Observer requests us to state that his reply to the "direct contradiction" given by Messrs. Crampton, Colles, and Carmichael, to his statement relative to the appointment of Mr. Adams to the Richmond Hospital, will be forwarded in time for publication in the next number of THE LANCET.

A Student, G. St.—One of Mr. Liston's excellent clinical lectures will appear in our next number.

A Surgeon—We have other reports of Dr. Wallace's admirable clinique before us ready for publication.

The statements of Mr. Soper with in reply to Mr. Way, are unavoidably omitted this week.

A Subscriber should endeavour to obtain the information from Dr. A. himself.

ERRATA.—In Dr. Rignold's paper, page 686, line 27, for *lombibuna*, read *lombibuna*; line 28, for *rubricea*, read *rubricea*.

Vol. I.]

LONDON, SATURDAY, FEBRUARY 6, 1836.

[1835-36.]

LECTURES ON DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE X. PECULIAR VARIETIES OF CEREBRAL HEMORRHAGE.

GENTLEMEN,—We have hitherto studied only the ordinary symptoms that accompany hemorrhage of the nervous centres; we have drawn merely a general picture of the most common features of the disease. It is now time to lay before you an account of certain varieties that you will meet with in the course of practice. The nervous symptoms are sometimes complicated with others that do not seem to belong strictly to apoplexy. They are even replaced altogether by phenomena of a different nature. What are those symptoms? In what do they consist? Where are they found? Certain of them arise from accidents occurring in the nervous centres themselves, the rest depend upon disorders in the other systems.

Spasmodic Affections of the Limbs.

The first class of symptoms which we have now to examine, is that depending on some lesion of the nervous centres, or of the membranes by which they are enclosed. They give rise to certain derangements of motility, or of the intellectual faculties, that are not ordinarily seen in cases of cerebral hemorrhage. Thus, in some cases, we observe contraction of one or more muscles of the trunk or extremities. This is evidently not a phenomenon of hemorrhage, whose grand characteristic is the production of paralysis; it depends on an

inflammation more or less intense of the cerebral matter surrounding the apoplectic cell. In other cases the limb is not contracted, but convulsed. We have seen certain examples where, in a short time after the effusion of blood, the limbs and side of the face were agitated by spasms, by convulsive movements coming on at intervals and with various degrees of intensity. These symptoms either may appear in the members affected with paralysis, or, while one side of the body is deprived of motion, the other is the seat of convulsive actions. Upon what do these phenomena, which occasionally manifest themselves as a consequence of cerebral hemorrhage, depend? Not in the effusion of blood certainly, for they are too rare. They occur too seldom to permit their arrangement under the symptoms of effusion. In many cases they are probably connected with irritation or inflammation of the nervous pulp or its membranes.

But are we to conclude on the existence of an inflammatory action in all cases where the spasmodic contractions now alluded to accompany cerebral hemorrhage? Does their manifestation justify the immediate employment of antiphlogistic measures?

Certainly not. Take care how you adopt implicitly such an idea. The most unfortunate consequences may be the result. Let us suppose a case in point:—An individual falls down suddenly, deprived of sensation and motion; he has been struck, in other words, with a violent attack of apoplexy. You bleed him copiously from the arm; the first abstraction of blood seems beneficial; but as the blood continues to flow he becomes agitated; convulsions soon make their appearance, and you are compelled to shut the vein, in order to prevent the continuance of a state which might have an unfortunate termination. This case is not certainly an exceptional one. You will frequently have occasion to meet with it in practice, but can we admit the presence of inflammation to explain the disorders of movement in the cases alluded to? No. The brain is in a condition quite opposite, and the convulsions depend, not on an excess of blood, not on inflammatory irrita-

tion, but on a partial anemia of the cerebral hemispheres.

There are certain other disorders of movement which accompany hemorrhage of the nervous centres, not as regular symptoms, but as extraordinary and rare phenomena; these also draw our notice in their turn. We have rarely had occasion, in only three times, to see patients labouring under the symptoms of cerebral hemorrhage, who presented a peculiar phenomenon of a very extraordinary nature; these individuals were at certain moments seized with an irresistible desire to advance, to run directly forwards, and, again, at certain other instants, they experienced the same irresistible inclination to go backwards. How are we to explain this curious symptom; this strange alternation of two opposite impulses? It is difficult to find a satisfactory reason; however, we may recall to mind, as connected with the subject, the experiments made by M. MAGENDIE to show the influence exercised by lesion of different parts of the brain upon locomotion. You may remember, that when M. MAGENDIE removed the hemispheres of the brain behind the corpora striata, he produced the first strange derangement of motion; and when he destroyed, or took away, the whole of the cerebellum, the animal, instead of advancing, constantly retrograded. Is there anything analogous to be observed in the cases of the patients to whom we have just alluded? Have we found any special alteration in the brain, which would account for the perversion of movement which they exhibited? These are questions which it is impossible to answer in the present state of the science; we have seen only three cases of the kind, and in these three we did not see the autopsy; we are not aware that many other examples exist in the records of medicine; the disorder of movement which consists in a desire to advance or retire by turns, is, in fact, a very rare phenomenon,—at least, in turning over the various works published on disorders of the nervous system, we have been able to discover only a single fact, which we propose to cite in brief detail.

In some cases of hemorrhage of the cerebellum, the effusion of blood has occupied one of the peduncles of that organ. Now, it has been proved by the experiments of M. MAGENDIE, that when one of the peduncles of the cerebellum is cut across, the animal, instead of constantly advancing, or retiring, as when the cerebellum is removed, shows a remarkable tendency to the circular motion; he seems incapable of getting forwards or backwards, but keeps perpetually spinning round on the same centre of motion; the body of a patient, who presented this rare and curious phenomenon during life, has been examined, and the lesion, a coagulum of blood, was found in one of the peduncles of the cerebellum. This is a

coincidence highly worthy of our attention, although it has existed in one single case only; we know of no other; this case was observed and reported by M. SEZARIS. The patient, a man, sixty-eight years of age, had been much given to the use of spirituous liquors; after an excess, he was seized with a desire to turn round and round, and when compelled to keep his bed for two months, he died. The same symptom predominated; the patient, unable to walk, showed the impulse under which he laboured, by constantly turning himself from one side to another in his bed.

These are a few of the anomalous symptoms, if we may use the term, which occasionally present themselves in cases of cerebral hemorrhage; but we may meet with complications that should be noticed. Thus some patients attacked with apoplexy are at the same time agitated by

Violent Delirium.

This is certainly a complication and not a regular symptom of the disease. The delirium attending certain cases of cerebral hemorrhage, depends on the existence of inflammatory irritation in the nervous pulp immediately surrounding the apoplectic cell, or on inflammation of the meninges in its neighbourhood. In other cases, instead of agitation and delirium, we observe a state of

Somnolence

different from that which usually accompanies and characterizes hemorrhage of the brain. The patient is plunged in a deeper degree of coma; he is more insensible than is ordinarily the case, and here we commonly find, as a cause of this exaggerated somnolence, a greater or less degree of serous fluid, distending the ventricles, or shed between the membranes lining the surface of the brain, and thus exercising a general pressure upon the organ. We now pass to an examination of symptoms that depend on

Lesions of some Organ independent of the Brain or its Annexes.

We frequently have occasion to observe inflammation of various organs marching with apoplexy, and of course modifying or complicating the ordinary phenomena of that affection. These disorders may be of an acute or a chronic nature. The former generally present themselves with a physiognomy altogether peculiar: their march is very rapid, and the patient soon dies in a state of great weakness and prostration. This latter circumstance probably depends on the state of compression of the brain, which influences the reaction in distant parts of the body. Again, eschars are very readily formed in persons labouring under cerebral hemorrhage. If the patient have been confined for any length of time to bed, the cutaneous integument is very apt to suffer from gangrene: thus you have two

points to remark in connection with certain complications of apoplexy. 1st. The facility with which inflammation may be developed in several organs, and the great tendency of that inflammation to present itself with adynamic symptoms. 2nd. The facility with which the integuments are struck with gangrene in the parts exposed to pressure. These two points are of great importance in practice. They teach you on the one hand to be on your guard against the secondary affections with which your patient may be attacked, and on the dangerous character of those disorders: while, on the other hand, they direct your attention to a state of the skin which, if neglected, may give rise to disastrous consequences.

The Duration of Apoplexy

is very various. However, it is a general principle, that this disease, except in cases extremely rare, does not kill the patient on the spot. In a few instances death has taken place in a quarter of an hour after the first symptoms of effusion. In other cases, which still are to be considered as excessively grave, the fatal termination does not arrive before the lapse of one, two, four, or even six hours. All these cases are more or less rare. In a great majority the duration of the disease is longer; and, however it may be contrary to popular ideas, you may hold it for certain that sudden death is much more frequently produced by a rupture of one of the great vessels of the heart, or of the latter organ itself, than by apoplexy. Indeed, experience shows, that in several cases of sudden death, we can find nothing to explain the immediate cessation of life. We may invent hypotheses to cover our ignorance, we may have recourse to physiological explanations more or less ingenious, but laying these aside as mere conjectures, we are compelled to avow frankly that in some cases we can find no pathological lesion whatever to account for the sudden manner in which life has terminated.

Progress of Apoplexy.

The march of cerebral hemorrhage is almost as variable as its duration. Frequently the symptoms go on augmenting, and the disease progresses gradually up to the moment of death. In many other cases we do not observe this constant march from the commencement of the attack to its end. There are relapses at different times; the patient is at one period much better than another, and this alternation of amendment and recrudescence may go on for a considerable length of time; this is by no means rare; indeed, we may say that hemorrhage of the nervous centres is one of the diseases most liable to relapse. When the patient has been once attacked, he has generally one, two, or three relapses, the last

terminating fatally, and hence the prognosis is in most instances very unfavourable.

Other Variations in Symptoms.

If you remember what we have said during the study of hemorrhage of the nervous centres, you will be prepared to allow several varieties of this important disease. Some of them depend solely on the seat of the lesion. Hemorrhage of the cerebrum differs from that of the cerebellum: of the cerebellum from that of the spinal marrow. Some varieties are formed by the nature of the accompanying symptoms. Thus we may have apoplexy with loss of consciousness; we may have it with a perfect preservation of the intellectual faculties,—two very different forms, you must allow, of the same affection. Again, other varieties are distinguished, not according to the presence or the absence of some great leading symptom, but according to the intensity of the symptoms in general. This latter is a good practical division, one that has been handed down to us from a distant period. Thus apoplexy has been distinguished into mild, into dangerous, and finally, into apoplexy of a middle character. This is an old distinction, and one that is useful in practice, for it leads at once to an appreciation of the most remarkable disorders. Between the two extremes of “mild” and “dangerous” hemorrhage, may be arranged all the great variety of forms which we have pointed out in the course of the two preceding lectures. Finally, other varieties refer to certain complications attending or succeeding the effusion of blood. Thus some cases are distinguished by marks of inflammation or other disorders in some portion of the nervous pulp. In other cases the seat of the complication is far from the brain, and consists in inflammation &c. of one or more of the great viscera.

TREATMENT OF CEREBRAL HEMORRHAGE.

We have now arrived at an important part of our subject,—the treatment of hemorrhage of the nervous centres. However, our observations on the point shall be concise; many of them are anticipated by what we have already said when speaking of cerebral hyperemia. The chief business of the physician in the treatment of cerebral hemorrhage is to follow and combat the accidents as they present themselves; or the treatment may be considered under another point of view, and regarded as preventive.

Venesection

is certainly the fundamental means on which we should depend. A large quantity of blood should be immediately abstracted from the system; we repeat, a large quantity, because it is important to make a sud-

den and efficacious impression on the circulation by taking away a considerable mass of the circulating fluid. In general we choose a vein for this purpose, and allow the blood to flow freely through a large orifice. The good effects of venesection may be referred to two principal circumstances; the first is, that it manifestly opposes the continuance of the hemorrhage into the nervous centres. The second effect is to remove any congestion of the cerebral substance by which apoplexy is so often attended, and thus give the patient a great chance of recovery from that accident. Again, we obtain no small advantage, by a copious abstraction of blood, from its effect in preventing the inflammation, which, as we have before said, tends to develop itself in the nervous pulp immediately surrounding the apoplectic cell, two or three days after effusion has taken place. Finally, venesection may facilitate the absorption of the coagulum, and thus hasten the patient's recovery by removing the material cause of the secondary accidents. Thus, you see, we can justify the utility of general bleeding in many respects, and you will have occasion to prove the truth of what we have said, when the active exercise of your profession shall call you to apply these principles in practice. Many authors advise the blood to be drawn by opening one of the large veins in the fold of the arm. Others, on the contrary, prefer opening one of the veins in the neck, particularly the external jugular vein; we would recommend you, in all cases, to choose the arm. You can manage this part of the body more easily than any other; you avoid any unpleasant, or even any dangerous constriction of the neck, and you are more sure of obtaining the quantity of blood you desire in a shorter time. Finally, some writers speak of choosing a vein in the foot; but this is an uncertain method of bleeding, and not accompanied with any advantages which can make us prefer it to venesection at one of the veins in the arm. Some of the older authors, and, amongst others, MORGAGNI, recommend us to bleed in the occipital veins, a method by which they say we act more immediately and certainly on the brain, but the practice is now completely abandoned.

Another question that has been discussed is the following; "On which side of the body should we bleed?" should the abstraction of blood be made on the same side of the body at which the loss of motion exists, or should we open a vein on the opposite side? All this seems of very little importance indeed: by bleeding on the side opposite the paralysis, you probably abstract blood from the same side of the body at which the effusion exists, but it is not easy to see how the state of the circulation in the brain is more influenced by this than if we took away the same quantity of fluid from the

other arm: the general effects are certainly more in proportion to the rapid abstraction of blood, and to its quantity, than to the choice of one vein rather than another. We have already drawn your attention to the importance of taking away at once a large quantity of blood; your first bleeding should rarely fall short of a pound, and may be repeated according to circumstances: the English practitioners are in the habit of bleeding very freely; they generally abstract 20, 25, or even 30 ounces of blood at a time, and the effects of this practice seem to justify its adoption. You will find certain contradictions to bleeding freely forced by some writers; thus they say when the face is excessively pale, the countenance sunk, the habit of body feeble and meagre, we should be sparing in the quantity of vital fluid we abstract, and particularly in repeating venesection, but I think we are not to attach any importance to the circumstances just alluded to: it is absolutely necessary to arrest the flow of blood into the substance of the brain, and to dissipate any congestion which may attend the hemorrhage; these two points should dominate all the minor considerations.

Again, it has been asked, "Should we bleed if the attack of apoplexy comes on after a meal, when the stomach is charged with aliments?" Certainly. The presence of alimentary matter in the stomach might perhaps induce you to defer bleeding in cases of a trifling disorder, but in apoplexy, where the existence of the individual is so seriously compromised, we should not hesitate to have recourse at once, and on the spot, to this our fundamental means of treatment.

Having combatted the first effects of cerebral hemorrhage by a copious abstraction of blood from the arm, we must have recourse again and again to the same remedy, according to circumstances: we must keep it in reserve against those symptoms of congestion that manifest themselves at certain periods after effusion has been fully established; we must have recourse to it whenever the appearance of certain phenomena, which have been described in our former lecture, would lead us to conclude that the nervous pulp surrounding the apoplectic coagulum has been irritated by the presence of the lesion, and is about to pass into inflammation; these are so many indications that point out the necessity of again opening a vein: however, let me remark, that you must proceed with caution, and observe what may be called a middle term in the practice of venesection: that when we have to treat a patient who is labouring under the immediate effect of cerebral hemorrhage, where we are called immediately after the attack, we should bleed once largely; we should even repeat venesection to the same extent as the first bleed-

ing did not answer expectations; but after one or two abstractions of blood, practised at a short interval, if the intelligence should still remain obliterated, if the pulse do not rise, if symptoms of reviving consciousness do not manifest themselves, beware how you persevere; the further abstraction of blood becomes dangerous, the loss of a few more ounces may rapidly aggravate all the symptoms; the coma persists and becomes more profound, convulsions appear, the breathing becomes stertorous, and your patient, from whom you have taken the slight chance of existence that remained to him, sinks rapidly from the abuse of a means, which, if managed with precaution would have been his safety.

I have more than once seen cases where the whole treatment consisted in the application of a few leeches behind the ears, or to the temples, with the administration of one or two irritating enemata to act as derivatives on the intestinal canal; yet with this simple medication, pursued for two or three days, the intellectual faculties were restored, the coma was dissipated, and nothing remained of the cerebral hemorrhage but its almost constant attendant, paralysis of the limbs. These cases prove that nature alone is often sufficiently strong to combat with success the accidents of apoplexy, for we cannot attribute any great effect to the loss of blood abstracted by a few leeches. However, we would not conclude from these that sanguineous emissions are to be neglected; we would only draw your attention to the fact, that venesection may be pushed too far, and that repeated abstraction of blood, in cerebral hemorrhage as well as in various other diseases, may give rise to consequences far from being beneficial.

An excellent work (*beau travail*) might be composed on

The Abuse of Sanguineous Emission.

Had any of you the time, he would confer a benefit, not only on our science, but on humanity, by showing how injurious have been the effects of venesection when pushed beyond measure, even in the treatment of inflammatory disorders. He might prove that bleeding, when repeated too frequently, in cases of acute pneumonia, instead of cutting short the disease, has, on the contrary, shortened the existence of the patient, who sinks under the loss of blood injudiciously abstracted. We might pass in review the history of all other affections, and prove the same circumstance. Diseases, whether acute or chronic, have certain periods, certain phases, through which they must pass, and it is in vain that we would arrest the march of nature, or turn her aside from the march she has chosen. The patient, on the other hand, requires a certain degree of force to carry him successively through these several phases; and to ~~maintain~~ strength by a wan-

ton abstraction of the vital fluid, in the onset of disease, is only to leave him without resource at a later period, when it is most imperiously required. Hence, I say, take away a certain quantity of blood in the commencement of inflammation, or of other diseases which require venesection; this is good, this is rational; but if you pass this quantity, you transgress the bounds of a sage moderation, and you injure the patient instead of relieving him. To ascertain this wholesome medium is the difficulty: to decide when we have pushed venesection far enough is a point that requires all our skill, experience, and knowledge; but this is a consequence of the nature of the science we profess. Were it not the case, the practice of medicine would be an easy task, and the healing art accessible without difficulty to the first comer that presented himself.

Arteriotomy.

We have hitherto spoken of abstraction of blood from the nervous system only, but the temporal artery has been frequently opened in cases of cerebral disease, and many writers prefer this method of blood-letting to any other: they think a more powerful impression is made on the system when an artery has been opened. However, this opinion is not supported by a sufficient number of facts to make us abandon the practice of drawing blood from one of the large veins in the arm, a method which we consider preferable in several points of view. An American physician has even gone so far as to open the radial artery, but this is a bold practice, which we would not recommend you to imitate: all the necessary indications may be completely and satisfactorily fulfilled by opening a vein, without any of the inconveniences that obviously arise from arteriotomy.

Bleeding by Leeches.

When a sufficient quantity of blood has been drawn in this manner, we may second the effects of our first one or two bleedings, by applying leeches in greater or less numbers to the temples, behind the ears, to the cervical region, the anus, the inside of the thighs or the vulva in the female: each of these regions has been selected by different practitioners, according to their different ideas, and there are, perhaps, circumstances under which one may be preferable to another. It is of importance that the patient's head should be constantly kept in an elevated position, and you may also follow up the application of leeches &c., by covering the head with cloths dipped in cold water, or with ice.

Revulsives and Emetics.

Some writers have advised the application of a circular ligature round the limbs; it is not easy to see what beneficial effect

can be expected from such a proceeding. It is much more rational to have recourse, as a secondary means of treatment, to revulsives of various kinds; these may be applied in the form of blisters, sinapisms, &c. to various points of the cutaneous integument; some prefer administering them internally: they may then be given by the mouth, or thrown up the rectum in the form of irritating enemata. Some writers, especially the older ones, were in the habit of recommending emetics in cases of cerebral hemorrhage; you will find this, I say, frequently mentioned as an auxiliary in the older works; but must we point out the absurdity of such a practice? Emetics can only be injurious when any determination of blood to the head exists; they are still more dangerous when effusion has actually taken place, and you can easily understand how the muscular efforts that accompany the act of vomiting are more likely to aggravate the patient's condition, than confer a benefit.

Treatment of the Paralysis.

We have now to consider the treatment proper to combat the effects of the hemorrhage of the nervous centres. Paralysis is the most frequent and remarkable of these phenomena. Can we oppose any remedy to the modification of movement? Can we hope to combat the paralysis with success? The greater part of the secondary phenomena, and the paralysis in particular, are nothing but mere symptoms; it is not to them that we must address ourselves, our means of treatment are here consequently unavailing. As long as the cerebral substance is compressed by a coagulum of blood, you can easily conceive that we can do nothing for the paralysis, which is its necessary and immediate consequence. Our first and main object must be to favour the removal of this clot, the cause of all the lesions which manifest themselves in sensation or motion. However, when we have reason to think the coagulum has been absorbed, or at least is nearly removed, we must not remain idle spectators of the helpless condition of our patient; we must do something. For this purpose we may apply stimulating substances along the limbs; we may excite the nerves which supply the members, or the nervous plexuses from which the nerves are given off. In these cases, nuxvomica has been administered internally with a good deal of advantage. When the paralysis is of very old standing, it is reasonable to expect some benefit by stimulating the muscles, the immediate organs of locomotion; they have in some measure forgotten to act; they have been enfeebled by long rest, by a forced inactivity, and require perhaps only some additional stimulus to restore their power, which now rather lies dormant than completely annihilated. This practice then may

be adopted in cases of ancient paralysis, but take care, gentlemen, how you have recourse to it rashly in more recent cases; the use of stimulants will, under such circumstances, be calculated to determine a still greater degree of cerebral congestion, which may give rise to the most fatal results. In individuals labouring under the consequences of cerebral hemorrhage which dates at a period considerably far removed, we often find it highly advantageous to support the strength by the gentle administration of ferruginous preparations; by a light nourishing diet; by occasional use of mild bitters, &c. In this way we support the constitution under the struggle it has to make, and by aiding nature in her efforts to remove the material cause of the disease we obtain a final triumph.

As to the hygienic measures that should be observed during the course of cerebral hemorrhage, they are exactly similar to those proper for congestion of the brain; it is therefore unnecessary to recur to them on the present occasion. We may now ask Do we possess any

Means of preventing the Occurrence of Apoplexy?

Authors have recommended the practice of abstracting a quantity of blood from time to time, in cases where this accident seems likely to occur. It is a good one whenever any of the indications of central hemorrhage present themselves with any degree of clearness; but unless these precursory symptoms exist, it is quite superfluous and unreasonable to abstract blood on the simple supposition that our patient may be attacked with the disease in question. The same remark holds good with respect to the use of the seton and several other means which are ordinarily employed as preventives of apoplexy.

Hypertrophy of the Brain.

We have now passed in review some of the principal maladies of the nervous centres, at least the principal of those maladies which are attended with an organic change of structure in the part. We have successively studied hyperemia of the cerebro-spinal axis, anemia, inflammation, and hemorrhage. We now arrive at a second class, in which no organic lesion is found, in which the disease rather consists in an altered nutrition, in a new arrangement of the molecules, without destruction or disorganization of the nervous mass; this second class likewise comprehends four grand subdivisions, which we distinguish into hypertrophy of the nervous centres, atrophy, *induration*, and softening.

When speaking of encephalitis, we showed how the nervous pulp might, under the influence of different stimulants, present the appearances of hypertrophy or ramollissement; but in the actual state of the science,

we are unable to say whether the immediate cause of these two conditions be inflammation or not; hence we are justified in treating them apart. Indeed, for the interests of the science, we are compelled to treat ramollissement apart from inflammation, for by pursuing an opposite course, we should be compelled to neglect or confound several most important facts. Go to the hospitals, observe diseases of the brain: follow the case of a patient who presents a certain *ensemble* of symptoms, and you will say that he has a ramollissement of the brain, and not an encephalitis. The former is associated with a train of phenomena with which you are familiar; the latter is not yet fixed in your minds, and it is for that reason that we have considered it by itself in the present classification of cerebral maladies.

We shall next take up the second portion of our subject, hypertrophy of the spinal marrow. This is an affection which you should distinguish with great care from hyperemia; however, in many cases, as we shall have presently occasion to see, the substance of the chord is pale and bloodless, at the same time that it is hypertrophied. The increased nutrition may, and often does, coincide with increased vascularity, but in several other cases we find it is in connection with anemia. "What are the anatomical characters of hyperemia of the spinal marrow?" This is a question, the answer to which we must defer until our next meeting.

NORTH-LONDON HOSPITAL.

CLINICAL LECTURES

ON CASES OF

STRICTURE OF THE URETHRA,

Delivered in the Session of 1836,

BY MR. LISTON.

LECTURE I.

GENTLEMEN,—You have had, during the last few months, many opportunities of observing the symptoms, consequences, and treatment, of strictures of the urethra, one of the most troublesome and dangerous diseases which the surgeon has to manage. You have had the opportunity of witnessing the cause, and I may even say the formation, of this disease, and of watching the development of the symptoms attendant upon obstinate contraction of the urinary passage of a most unmanageable form, viz., that following injury of the perineum.

CASE.—A man was admitted, J. D., 35

years of age, who, while going to his work early in the morning, when it was dark, slipped his foot into one of those apertures that are made in the pavement for throwing down coals. In some way or other he struck his perineum on the edge of the opening, and so great a quantity of blood escaped as to make him feel very faint. About seven hours afterwards he applied to the hospital, when, very properly, a catheter was introduced, or attempted to be introduced, but the instrument appears to have got entangled in some laceration, and a quantity of blood oozed out, although the greatest gentleness had been used. When I first saw the patient there was some swelling of the perineum, which became tender on pressure. Leeches and fomentations were applied, and he was discharged some two or three weeks afterwards, apparently very well. He returned, however, on the 25th of September, complaining of very great difficulty in passing urine, he having been dismissed on the 1st of that month. He was taken back as an out-patient. There was evident hardness of the perineum, and very great difficulty was experienced in passing the catheter; in fact he now suffered under a stricture of the very worst and most unmanageable kind.

Now a patient in such a situation, with stricture of this rigid kind, is in constant danger. He is in great risk of urinary abscess, and of extravasation occurring into the cellular tissue. He is, from the least excess, liable to complete retention of urine in the bladder, and if that be not most properly and promptly treated, fatal consequences may ensue, or he may be reduced to such a state that his after life will be so embittered as to be scarcely worth retaining. There is, in fact, no disease in which a person is more apt to be "bungled out of his life," than in retention of urine, whether from strictured urethra or any other cause. But even slight forms of the disease will bring upon the patient considerable suffering, mental and bodily, great irritability of temper, and serious interruptions to the complicated and important functions of the organs attacked, —even impotence, to some extent.

A great variety of disorders of function, and changes of structure, in the neighbouring parts, connected by sympathy or function with the urinary passage, have been supposed to depend on disease in that canal, and to be removable by putting it into a sound condition. There is much truth in the doctrine, though the treatment must not stop short at that point. Many diseases are certainly engendered or kept up by a disordered and irritable urethra, and the removal of that state enables the surgeon to apply his other remedial means with double effect. Many affections of the bladder, of the testes, of the prepuce, of the verge of the anus, can be much more readily

and certainly put to rights by attention to the point in question. There is a man up stairs in No. 3 ward who is labouring under stricture. He passes his water very frequently; there is great swelling and redness of the scrotum and prepuce, and ulceration about his glans penis, which for the present forbid any attempts to introduce instruments. He is passing much puriform matter with his urine, which is discharged with great difficulty, and frequently we shall find in such cases a very bad stricture to be causing all the mischief. The testicle is apt to suffer, often becoming swelled in consequence of irritation in the part; the prepuce thickens and contracts; and persons labouring under stricture have more or less uneasiness about the verge of the anus. There is a certain uncomfortable feeling, and a bearing down, great pain, and often difficulty, in passing the stools, and great exertion is called for on the part of the abdominal muscles to empty the bladder; you find also that the bowel is emptied at the same time, there is an evacuation of flatus, and very often of the more solid contents of the bowels. The patients, from the constant straining, are apt to have a determination of blood to the part, they labour under piles, and hemorrhoidal tumours internally and externally, and, very often, there is considerable falling down of the bowel. Other symptoms arise from irritation of the urethra, and among them many painful affections in the lower limbs. Neuralgic often hinge upon urethral derangement, and general and local treatment alike fail, together or combined, in affording relief, until this is looked to and remedied. I have now under treatment a man under thirty years of age, who had been actively treated during at least eighteen months before I saw him. He complained of violent and almost constant pain in the course of the left sacro-sciatic nerve. He had been cupped many times, as often as four times a week; he had had blisters and sinapisms applied, and he had tried all sorts of drugs internally; indeed he must have had the stomach of an ostrich to have got quit of the mass of horribly poisonous stuff put into it in the shape of medicine, and he had nearly ruined himself by the purchase of expensive and fashionable drugs, without obtaining even temporary respite. From a highly respectable chemist who supplied the patient, I have a list of the remedies used at various times. It comprised delphinia, strychnia, veratria, aconitine, colchicum, Dover's powder, and, lastly, carbonate of iron in immoderate quantities, though he might, under the circumstances, have, I doubt not, swallowed the chain cable and best bower anchor of a first-rate boat, in the form of rust, without being one whit relieved. Such, at least, is my impression. The state of his urinary organs had never been inquired into, or at

any rate attended to. He laboured, and had done so from before the neuralgic attack, under difficulty in passing his water. It came away frequently in a small stream, and with much straining. In the space of fourteen days, and by a few introductions of proper-sized bougies, beginning with a very small one, the pains all but left him, and he is now rubbing in, and it will be with effect, an ointment containing the most valuable of external narcotics, the veratria and aconitine, in the form recommended by Dr. TURNBULL. This is another instance, if any were wanting, to convince you of what I am constantly insisting upon, namely, the necessity of inquiring for, and searching out, the cause of surgical disease, as the first and most effectual means of cure, and doing away with that, if possible, whatever it may be. Pains of a gouty nature in the lower extremities often disappear upon the removal of disease or disorder of the urethra, and many patients have expressed to me their astonishment at the exemption from their usual sufferings consequent upon disorganization and debauch, after their urinary organs had been put into a right condition.

The remedy in such slight cases of stricture is readily applied, though, even there, skill and great caution are essential to the patient's well-being and safety. By rash, harsh, or frequent interference, the disorder of function may be increased instead of being alleviated, and in place of a trifling and easily remediable contraction, perhaps only a slight tenderness of some portion of the mucous lining, with irregular action of the surrounding muscles, a narrow and confined stricture may have its foundation laid, occasioning a contraction so tight, as to admit with difficulty and reluctance any instrument larger than a common probe, and surrounded by a substance almost as unyielding as fibro-cartilage.

Now stricture is produced in consequence of inflammation of a violent character. It does not naturally follow all inflammations, otherwise the great majority of the male population would assuredly labour under this troublesome disease. There are a great many young men who have had gonorrhoea, again and again, without experiencing the least difficulty after the cure has been completed, or, in the after period of life, in making water. Many people are exceedingly liable to gonorrhoea, and if they expose themselves to it much, they may perhaps have suffered under that infection a dozen or twenty times. I have seen patients who have had it as often as that, and still have not laboured under stricture. The inflammation in these cases is not of a violent character; it is attended with a discharge, which gradually subsides; but if the inflammation be in any way excited beyond a certain point, if it be excited in consequence of the discharge being suppressed suddenly

by debauchery, or by the improper use of injections, or if it be excited by (excellent remedies when judiciously and timely employed) the introduction of instruments during the inflammation,—if a bougie, for instance, be introduced during gonorrhœa, which is sometimes the case; and if that bougie be introduced forcibly, the inflammation will run so high, that it will be followed by the deposition of lymph in the cellular tissue, or, perhaps, on the surface of the lining membrane. But the worst cases of stricture are those which arise from external injury. They may occasionally be attributable to internal injury. There is also one case here, by-the-by, which shows remarkably well the cause of stricture. Two very strong reasons are seen, why the man should have suffered from this disease. Two very powerful exciting causes were applied. The man was aged 47, and was admitted on the 17th of December 1834. About six years ago, when rigging a vessel, he fell from a height of about thirty feet, and came astride upon a boom. He complained of severe injury in the loins, which was removed by cupping, but had then no affection of the urinary organs, excepting some hemorrhage from the passage. About four years ago, that was two years after the injury of the perineum, after being over-heated, and drinking a large quantity of cold beer, he was seized with retention of urine. He applied to a surgeon, who forced a large catheter into the bladder, and drew off the urine. This proceeding was also followed by profuse hemorrhage from the urethra. From that time he has complained of pain and difficulty in passing water. Now the cause of the retention no doubt was a stricture, occasioned by the bruise on the perineum, which perhaps did not attract his attention very much, afterwards aggravated by the debauch. While over-heated, he drank a quantity of cold beer, and inflammatory swelling of the thickened part followed; then a fresh injury was inflicted upon the urethra, the mucous tissue was very likely torn up extensively, and this was followed by fresh inflammation, which terminated in one of the most troublesome strictures I have encountered. He had a copious discharge of puriform matter from the urethra, and retention of urine occasionally supervened, but was relieved by fomentations. He had been twice under treatment, and derived considerable benefit from the measures that were then adopted. Upon his admission, some induration was felt along the course of the urethra and perineum. The stream of urine was small, and gave rise to considerable smarting, and sometimes great pain. The urine was opaque, and was discharged, with a great quantity of mucus. A catheter was introduced on two different occasions, and retained for some time, but not so long as

could have been wished, as the patient was irritable, and difficult to be managed. It was an exceedingly unyielding stricture, and there was for some time very little ground gained by the introduction of bougies. We were, you may recollect, under the necessity of leeching the perineum more than once, of correcting the state of his digestive organs, and of allowing long intervals to elapse betwixt the introduction of the catheter. He got into the service of the hospital, but had not long been in it before he was dismissed. He got doing some mischief or other, and was discharged, but not before the introduction of No. 8 catheter had been effected. I believe, when he went away, he made water perfectly well, the mucous discharge having ceased. As had a case as I have ever seen, arose from the laceration of the passage while the patient was yet a boy. I saw him labouring under dreadful difficulty in making water, and the urine was mixed up with an immense quantity of vitiated mucus. Sometimes the irritation was very violent, and the call to make water almost occurred every half hour. I had him brought from the country, and most actively treated. When a boy at school, he was seized with retention of urine in consequence of exposure to cold. The surgeon in the country had no proper instrument with him, and he endeavoured to relieve the patient by pushing in the handle of a spoon, with a small twisted old-fashioned handle, for helping sugar. This operation was followed, not by the evacuation of urine but of blood, and ever after that he had difficulty in passing urine. The stricture became confirmed, very likely fresh causes were applied, and the passage was inflamed again and again. Perhaps he had again and again gonorrhœa. In fact there is no saying what additional causes existed for the stricture. We often find, that very many causes have been in operation, an external bruise, for instance, when it is lucky for the individual if nothing else happens, for sometimes the symphysis pubis is separated, or the bones are broken, or a portion of bone enters the bladder, an injury which is almost always fatal within the first 24 hours; and if the patient escapes from the dangers of effusion of blood in the cellular tissue, and obstinate retention of urine, the foundation of the worst kind of stricture is laid. When I left the infirmary at Edinburgh, I had under treatment a man with very bad stricture, the cure of which was materially retarded by an attack of erysipelas of the face, followed by inflammation of the upper part of the windpipe and the fauces, with a profuse discharge of purulent matter. (Mr. Cooper had a patient who died after an attack of erysipelas from a disease of this kind—a sort of purulent laryngitis—and you may recollect that he showed you

one of my drawings of this appearance.) The patient of whom I last spoke, ascribed his stricture to his having slipped in stepping over a rail, on which he fell astride. I have seen various cases of strictures from blows. I had under treatment at one time a stricture produced by a kick with a heavy shoe, which I thought I never should overcome. The water passed only in drops. I failed again and again to introduce instruments. I got the catheter fixed in the stricture, but by no possibility could I get it through, and I had determined, as in the case of C. M., now in the house, to cut into the perineum, divide the urethra behind the stricture, bring the knife forward, and expose the extremity of the catheter, introduced as a guide, and thus be able to pass the instrument into the bladder, and there keep it. He was placed on the table, and tied up as for lithotomy, when I found the stricture yield a little, and on persevering I succeeded in getting a very small catheter into the bladder, and then, as you are aware, the cure was in my power. So in C. M.'s case, by a little perseverance on the day on which I thought of cutting into the perineum, I accomplished my object, and a very rapid and satisfactory cure resulted. I had a young patient, who, before I took charge of the Edinburgh Hospital, had been operated upon there, in whom the stricture was occasioned by the kick of a horse in the perineum—an odd place, by-the-by, for such an injury, for one cannot very well understand how the horse's hoof could reach the perineum. The scrotum was bruised, the part behind had also suffered. He richly deserved the punishment, for I believe he had put a furze bush under the horse's tail, and was tickling him in that tender region. He was afterwards further punished, for his perineum was cut into without any object being attained; when he came under my treatment, a catheter was passed, and retained for a short time. I sent him home again, but some hours after he was seized with retention of urine, and he was brought to me in great suffering and agony. A catheter was then re-introduced and retained until a profuse discharge took place, when the stricture yielded. The cure was completed, according to the method which I shall detail by-and-by.

Stricture also arises in consequence of the laceration of the passage in extracting stones, or from large stones being forced along by the impulse of the urine. We had a case, some little time ago, of false passage in the urethra, a fistulous aperture, through which the greater part of the urine was discharged, after the extraction of a stone. It appeared, from the history of the case, that the boy had laboured under stricture, from some cause or other. The stone had come down from the bladder, and had stopped behind the stricture. He was ad-

mitted into an hospital; I shall not say where, as it is not my wish to offend any one (many in the profession are uncommonly thin-skinned); the stone was cut out about an inch and a half behind the orifice. He took no great care of himself after that. Bougies were introduced in order to overcome the stricture, but the opening could not be made to close again. He was admitted labouring under retention of urine, and was relieved completely by the employment of fomentations; the stricture was dilated, so that Nos. 5, 6, or 7 catheters were admitted readily. The boy did not submit to treatment very well; he was opposed to such means as would have removed the cause, which was the first object, because the abatement of the stricture was essential to the closing of the false passage. Something more, however, would have been required. But it is very difficult to close up openings which are anterior to the scrotum. I do not know what the circumstances were that rendered an opening necessary, but if it had been possible to bring the stone through the orifice, and by introducing an instrument along the urethra, so as to divide the contraction, without injuring it from without; or, if it had been possible to push the stone back, no such bad consequences might have happened. I caution you against making an opening into the anterior part of the canal, for you will find it almost impossible to get the opening closed up again. Had the stone been thrust into the perineum, which it could have been without any risk, and cut out from thence, there would have been no fistulous aperture. I am not an advocate for dividing the stricture from within by the use of cutting catheters or other contrivances, but in a case where the stricture is near the orifice, almost within sight, I do not think that any injury would result; and certainly an incision into the perineum would be attended with less troublesome consequences than the incision anterior to the scrotum.

Having said so much to you about stricture, it is time that I should describe to you the symptoms. Slight stricture, especially after the parts have been excited, causes a frequent desire to make water, a scattering of the stream, and occasionally a discharge, a sort of gleet. The patient may apply for relief from some uneasiness in the perineum, or swelling of the testicle; when stricture is more confirmed, there can be very little doubt, from the symptoms, as to its existence. Then the water is passed only in a very small stream, indeed, sometimes, only in drops, and with great straining, and strong impulse on the rectum, for the parts sympathize closely, and are acted upon by the same muscles.

When the stricture is pretty well confirmed, the patient often supposing he has wholly emptied the bladder, may find a quantity of

water run off, in a minute or two afterwards, mixed probably with a quantity of viscid mucus. This is easily explained. In stricture, changes take place in the urethra, as well as in the bladder. If the stricture increases, the muscular coat of the bladder becomes very much contracted, and the cavity is diminished in capacity, and its mucous surface is altered, and in the urethra, more especially behind the contracted part, there is a dilatation, as may be seen in many preparations on the table. You find in a recent specimen the mucous coat always exceedingly thick, and loaded with dark-coloured blood. The muscular coat is four or five times thicker than it ought to be. The passage becomes very much dilated, generally speaking, behind the contraction, the necessary result of the stricture becoming tight. Sometimes great quantities of water collect in the pouch thus formed. Sometimes it is like a small bladder, and, not unfrequently, calculous matter collects in it; stones form in the perineum in this way, and it is from this pouch that the water oozes out after the calls to empty the bladder have gone off, and the patient has readjusted his habiliments; and if the patient be in the humbler ranks of life, and cannot constantly change his apparel, he is scarcely fit to be approached, for he smells as rank as a polecat.

The stricture, in the first instance, may involve but a very small part of the canal, presenting only such a contraction as might be produced by tying a firm small cord around the passage. But inflammation recurs, from time to time, from various causes,—from injections, or from some injury of the parts, either from without or from within; or the urine being obstructed may be impelled against the part with great force, and cause inflammation. Fresh depositions of lymph thus take place, and, ultimately, the limited stricture extends until a hard cord can be felt surrounding the passage, and increasing the contraction perhaps to the extent of an inch, or even more. This hardness in the perineum is found to obstruct the catheter, and you can take hold of the cartilaginous mass in guiding the instrument through the unyielding tissue, and the introduction is only accomplished in many cases after a good deal of perseverance and pressure.

If means be not taken to relieve this disease, ulceration is apt to ensue in that part of the canal into which the urine is constantly impelled. If the ulceration be rapid, or sloughing occur, there is a risk of the urine being extensively infiltrated in the cellular tissue; but, generally, if the urine be not completely retained in the bladder, it escapes, though in small quantities, through the urethra; the parts around the urethra become condensed and inflamed; and abscess may come slowly to the sur-

face, which, being opened, evacuates a quantity of well-digested but solid matter. A day or two may elapse before the inflammatory swelling subsides, when the urine begins to run through the cavity of the abscess, mixed with matter of no pleasant odour. Often the greater part of the water will come through this passage, and if the stricture becomes more and more confirmed, the whole of the water may at last pass so. One patient now under treatment here is somewhat in the condition described. C. M., aged 42, was admitted with a fistula in perineo, through which the greater part, if not the whole, of the urine, was passed on admission, in the first instance, and that not very freely. When this is the case, the stricture very often yields in some measure. It is not so much excited, as the water is not impelled with such violence against it. This patient had been long under treatment, and at one time great progress was made towards a cure. But, latterly, through his own carelessness, a great aggravation of the complaint had occurred. It was, for months previous to his presenting himself here, found quite impracticable to reach the bladder, with any sort of instrument. Caustics and cutting instruments from within had been employed, as is usual, without benefit. We occasionally meet with cases in which one abscess forms after another, and the scrotum is perforated by holes,—six, eight, or a dozen papillæ presenting in the scrotum and perineum, the whole of the water coming through them. I have treated several such cases, external injury or mismanagement having caused the passage to close entirely, not, however, without cicatrization of the surrounding tissues. Cases occasionally occur in which not a single drop of water has passed *per vias naturales* for several months. I had one case where nothing passed through the urethra for eighteen months, and I recollect another in which nothing was passed through the urethra for fifteen years. The man positively declared that not a single drop of water had passed through the urethra for that period, though he was not very far advanced in life. How he could so long submit to such inconvenience and suffering I cannot comprehend.

What is necessary to be done under such circumstances? I believe that it is only in these cases,—when you cannot by any possibility introduce the catheter,—that you should be under the necessity (excepting also in cases of extravasation) of making incisions into the perineum. I was, in the two cases to which I have alluded, very much afraid lest I should be obliged to put in practice an operation which is pretty often had recourse to unnecessarily, I suspect, that is, incision of the perineum, and division of the stricture from behind forwards, when the water was still passing

through the urethra, though in a very shabby way; but ultimately in both of them the catheter was, by cautious and persevering efforts, got into the bladder, and a cure was then accomplished without difficulty or delay.

I said that gradual ulceration frequently leads to abscess. Here is a very good specimen of it. Observe a ragged hole opening from the urethra into the cavity. The specimen was obtained from the body of a very old man who died from the effects of extravasation. The ulceration was recent, and here you perceive is the cavity of the abscess. By the progressive ulceration the matter gradually came to the surface.

But where the urine is retained, and the stricture, from the inflammation within, is entirely closed, a different result follows. Retention of urine, I need not tell you, is very alarming, and very difficult for the patient to bear. The symptoms come on very speedily, where stricture is the cause. The bladder, though not so very much thickened, as in this remarkably beautiful specimen, is, almost uniformly, much contracted, and incapable of being dilated to any extent. It will sometimes contain six or eight ounces of urine, and sometimes not above half that quantity. The symptoms of retention, therefore, come on at a very early period, and consequently the danger is very great. In a few hours after the symptoms have commenced, the patient, perhaps, thinks he is relieved, he feels as if water dribbled away from him, he has a sensation of heat in the perineum, and he is speedily afterwards alarmed on finding a large swelling in the scrotum, urine having got into the cellular tissue in consequence of sloughing of the dilated part of the canal; or the cyst in the abscess having given away by the same process; or an abscess by rapid ulceration, perhaps, has been forming, in close connection with the urethra, by the compression of which the urine is prevented from passing along the canal. You see this happens now and then during the progress of gonorrhœa. An abscess forms and impedes completely the passage of the urine, without any contraction existing in the passage. I had once under treatment such a case of gonorrhœa, the abscess being very deeply seated, in which the urine was arrested in its flow for the best part of three weeks. It is not a good practice to introduce instruments in acute inflammation of the passage, but in that case it was necessary, for ten or twelve days before I saw him, to introduce a catheter two or three times a day, to relieve the bladder. There was a sort of chronic abscess formed down by the side of the rectum, and it was only when it became apparent, and was evacuated by incision upon my first visit, that the patient got relief, and had the functions of the parts restored. Now where the patient makes

violent efforts to pass water, the cavity of that abscess, connected with the dilatation behind a tight stricture, is filled with urine, as well as the posterior part of the canal, and the parietes of the abscess give way, so as to permit the escape of the fluid, containing much saline matter, and very acrid, into the cellular tissue. The cyst does not burst, as some writers assert, nor does the urethra; but they either slough or ulcerate. Some patients, with retention, get through by active and judicious management, but a great many are lost, from even slight extravasation of urine. Another very great risk, in all these cases, from such an occurrence, that a fatal termination takes place at a very early period, and without time being given for the destruction of the cellular tissue, the urine seeming to act on the constitution as a poison. It is rapidly effused, and attended by a secretion of putrid sanies, with a sinking of the powers of life, and a speedy termination in death.

I should have mentioned before, that we find stricture occurring at various parts of the passage—strictures from injury. The very worst kinds are generally met with in the posterior part of the canal corresponding to the perineum, in the widest part of the urethra; but the strictures generally met with arise from acute inflammation, produced by the introduction of instruments, or the suppression of discharge. They generally occur in that part of the canal which is anterior to the sinus of the urethra, at three or four inches from the orifice. Strictures occur in the membranous portion of the canal, and they occur also, although not so often, very near the orifice. These are exceedingly unyielding, though *why* I cannot tell you, but contraction of one part often leads to contraction of another. Say that the passage is contracted behind, in the membranous portion, and the water does not come away in a full stream; the canal is never fully dilated. Naturally, one of the narrowest parts of the canal is at about three or four inches from the orifice. Here coarctation takes place, and also at the orifice, which is the tightest of all. The whole canal is, to a certain degree, diminished in caliber, and these parts more than any other. The disease very seldom exists singly. Other parts of the canal are generally affected, besides that which is first observed. In most cases you will be able to pass a catheter so far, say, through an obstruction at three inches from the orifice; but then an obstacle still exists further back. Perhaps the commencement of the membranous portion of the urethra is as badly thickened as the anterior. Before we next meet, I shall think on the subject carefully, and if I have now forgotten any of the symptoms or the circumstances connected with stricture, I shall then make up

for it. I shall then speak of the treatment. You have seen many cases here, but many more cases are met with in private practice which are not admissible into hospitals, the danger is so very slight. Only the worst cases of stricture are admitted here. It is right that you should understand this, and you should be prepared to treat them *scientifically*. But there are a great many very difficult cases, for, indeed, many patients labouring under this disease have been "bungled out of their lives" through ignorance and inattention. This drawing represents mortification of the scrotum from extravasation of urine. Patients do not often survive under such mischief, or until the parts become thus disorganized; some struggle through wonderfully, and if incisions be not made, as they ought to be, very early and very freely, the scrotum or the penis is often left uncovered and unprotected.

I should mention that occasionally the passage ulcerates towards the corpus spongiosum, and the urine is admitted into the vascular network, the penis becoming black in consequence. It is not into the body of the penis, but into the corpus spongiosum, that the infiltration occurs. The outer surface of the glans, as you are aware, communicates freely with the spongy body, is, in fact, a prolongation of that tissue. When the glans becomes black, and sloughs, it is about one of the most alarming and fatal signs which we meet with, and many are alarming enough in the disease. This is not a very common occurrence, but Sir BENJAMIN BRODIE mentions, I think, two or three cases in which he noticed it, and in all, the patients, I believe, perished. I have seen the appearance also more than once, but in one of the instances a fatal termination did not happen. The urine may in this way be admitted at once into the blood, and be returned by the veins into the mass of circulating fluid, and thus you can account for the bad consequences which almost invariably follow, but still a fatal result does not uniformly take place.

CURE OF ULCERS.—Dr. Cramer recommends for the treatment of ulcers, that a piece of lint, imbued with the discharge, should be dipped in an impalpable powder of the nitrate of silver, and then reapplied to the sore. This he repeats every day, or every other day, and by his enforcing a quiet state of the member, he mentions his having succeeded in healing the most obstinate ulcers in a period of six or eight weeks. He has likewise employed the same powder with advantage to the granular conjunctiva.—*Heidelberg. Klinische Annal.*

JERVIS-STREET HOSPITAL, DUBLIN.

CLINICAL REMARKS

BY

DR. WALLACE.

FRACTURES OF THE JAW.

JANUARY 19, 1836.—Ward No. 4.—Here, gentlemen, is a case of fractured jaw in a woman; let us compare it with the one in the man in the ward No. 2: the comparison will be useful. What are the relative situations of the fractures in these two cases? You saw that the man's fracture was situated just at the right side of the symphysis, that it passed between the first and second incisors. And here let me remark, that fractures of the jaw, although they are said to occur at the symphysis, never do take place in that situation, not really in it. This is what you might expect, when you reflect that the symphysis is much stronger than the part of the bone just connected with it, or at the side of it. You remark, that this woman has a fracture on the right side in precisely the same situation as that of the man, but you see she has got a second fracture; the bone is broken on the left side also, immediately in front of its angle. This renders her case far more serious than that of the man. Observe what a difference there is between them. You saw that the man appeared to suffer very little, and there was scarcely any deformity. See how much the fragments are here displaced; remark how this woman appears to suffer, what agonizing pain she seems to experience about the fractured angle, how the least motion of the head annoys her, and how she grasps her occiput with her hand to keep her head steady. She discharges abundantly saliva from the mouth, and is almost quite unable to articulate, whereas the man could speak very distinctly. What is the cause of this great difference in these two cases? I have often observed many of the distressing symptoms which you see in this woman, to arise when the jaw was fractured far back; and I have always supposed them to be owing to the injury of the trunk of the sub-maxillary nerve, which you know enters the bone near its angle, and is, therefore, much exposed to injury in such cases as the present, that is, when a fracture exists near the angle. There is also another reason why the double fracture in this woman should produce much more serious consequences than the single fracture in the man. The depressors of the jaw are almost all attached to the middle fragment, while the elevators are connected with the two posterior portions of the jaw; hence great displace-

ment must arise by the different parts of the jaw being pulled by their muscles in different directions. The middle portion is depressed, and the posterior portions are raised, and this displacement is greatly facilitated by the direction of the fractures, which is parallel to the line of direction in which the depressing muscles act, that is, from above downwards, and from before backwards. But in the man's case, the elevating muscles being connected with both fractured portions, the action of the depressors, which are connected with the large fragment, are greatly moderated, and hence there is little displacement.

Now how have these fractures been produced? How has the fracture in the man been produced? By a fall from a ladder on the chin. How has it been produced in the woman's case? By a blow on the left side of the jaw. You can easily conceive, that the mechanism of the forces which caused the fractures in these two cases near the symphysis was different, that is, the force did not act in the one case, as it did in the other. In the man's case, the tendency of the force was to straighten the jaw by pressing the convexity of the chin inwards and backwards, and the solution of continuity close to the symphysis commenced in the inside of the jaw, and extended outwards. In this woman's case, the force being applied to the side of the jaw, the tendency of its action was to increase the natural curve of the jaw, and the fracture near the symphysis must have commenced externally, and passed inwards, and most probably the second fracture occurred subsequently to the first, but by a continuance of the same force.

What difference of treatment must be adopted in these two cases? You have observed that the man seems to be very comfortable under his injury; and all that has been done has been to retain, by a bandage passed under the chin and over the head, the lower jaw against the upper; bits of cork being previously interposed between the teeth at each side. The same treatment has been adopted, you observe, in this woman's case, where there is a double fracture, but you see it does not answer. You see how much she suffers. Now we shall give her great ease by adopting the proper mode of treating such cases. The plan is to interpose a grooved cork at one side only, that is, at the side that is elevated, and then gently apply a bandage under the base of the jaw, so as to raise as much as possible the depressed side. Now let me explain to you the principles of this practice. Look, first, at the state in which the bones are. You remark that the portion of the jaw interposed between the two fractures is much depressed. This depression is caused, as I have already explained to you, by the contraction of the depressing muscles, and by the weight of the unsupported fragment of

jaw. You also remark what pain is given, whenever I attempt to raise this depressed portion into contact with the upper jaw, or to a level with the other portion. You see she will not allow this to be done; you cannot, in fact, by acting in this manner, either bring or retain the bones in their proper situation, and even if no pain were produced, the mechanism of the parts, and the direction in which the displacing muscles act, would soon render your endeavours unavailing. Well! what should be done? You must, as I have said, depress the raised part, you must bring it down to a level with the broken fragment; and you do this by interposing a cork between the upper jaw and the raised side, proportioning its thickness to the degree of displacement. You thus depress the raised side, and make it meet the depressed side. I shall now put in this cork at the raised side. See what relief it affords; I shall next pass this in at the other side. You remark she cannot bear it; I must remove it. Now I shall apply a bandage, as we did in the man's case. This, then, is the mode of treating these fractures. In the one case, you apply a cork at both sides; in the other, you apply it at one side only, and you see how admirably the difference of treatment is suited to the two cases. I should mention to you, that it will sometimes happen, that it will be useful in cases of double fracture to apply a second cork; for example, in the present instance we might apply a cork between the posterior teeth at the left side, not as it was applied between the upper jaw and the depressed fragment, but between the upper jaw and the posterior and left fragment of the lower, which is, as well as the right side of the jaw, kept raised by the elevator muscles. This would keep this portion of the jaw down to a level with the posterior end of the depressed middle fragment. I generally, however, find that this second cork is not necessary, for there is not in this part so much displacement as anteriorly. The cause of this you will easily comprehend, when you consider the attachment of the depressor muscles.

Let me make another remark to you. You might suppose that as a fractured jaw is subject to constant motion in speaking or deglutition, its reunion would not be easy. The reverse is, however, in general, the case, and I have often been surprised at the rapidity and satisfactory mode in which fractures of this bone unite, even in cases where from the carelessness and garrulity of the patient you might augur the worst. It is really very remarkable how admirably nature often works out her object in these cases: yet, I have sometimes seen these fractures remain ununited, and have then had occasion to verify the remark of Boyer, that it is surprising how little the disunion affects, after a time, either mastication or

enunciation. Dr. Physick, of Philadelphia, succeeded in causing reunion in a case of this kind, by the seton. I have also observed, on some occasions, union to have taken place with deformity. Hence, in saying that these cases turn out well, although little attention be paid to them, I am making only a general remark, and this must not induce you to pay a lax attention to them.

Ward No. 8.—Oh, another fractured jaw! How was this caused? (The house-surgeon replied "that she had been thrown down last night by a carriage in the street, that she was brought into the hospital in a state of insensibility, and that it was supposed a wheel had passed over her head.") Although there is, gentlemen, considerable swelling and tenderness in the fractured side of the jaw, and about the parotid, there does not appear so much injury as would probably have been caused had a wheel passed over the jaw. The fracture may have been produced by a simple fall on the jaw. Let us see where the fracture is: you remark that it is not in the situation of the fractures in either of the other cases: it is a single fracture, and corresponds to the interval of the first and second incisor of the left side: you also remark the nature of the displacement: the left or smaller portion is drawn outwards, and the larger inwards and backwards. There is scarcely any perpendicular displacement; this is owing to there being elevator muscles attached to each fragment. You remark that she has much more pain than the man in Ward No. 2, but less than the woman in No. 4. You see I can easily replace the parts in their proper position, by pulling outwards the left or smaller portion of the jaw, and by pressing backwards the right portion.

You may suppose, from the facility with which the fractures of the jaw in these three cases have been detected, that their diagnosis is always very easy; so it is if care be taken. You are, however, aware, that only a few days since, a man who had been discharged from prison, came to the Dispensary with an injury of his jaw, and when I told him that his jaw was fractured, he replied that he had himself told Surgeon — that his jaw was broke, but that he desired him to go about his business, that there was nothing the matter with his jaw. You see, therefore, that attention is requisite, and upon some occasions considerable attention is necessary, to detect a fracture of the jaw; for it may happen that there is no displacement whatever, and a crepitus may be evident to the patient, when it can scarcely be detected by another person.

HYDRIODATE OF POTASH IN SYPHILIS.

Ward No. 6.—You are, I am sure, gentlemen, attending closely to this man's most

interesting case; see what an alteration in his countenance; he has been in the hospital only a few days: when first admitted, he kept the ward awake all night, as I was informed, by his roaring out with the agonizing pains of his bones, and particularly of his shins. He says he now rests most comfortably: his shins were, on his admission, so uniformly swelled, from the knee to the ankle, that no defined prominences could be felt along the tibia, and the soft parts covering these bones were so tender, that he could not suffer the least pressure to be made on them. You see this is not now the case; there are a number of projections or exostoses, to be felt, and although the whole tibiae are still much larger than natural, they feel vastly smaller than they did four days ago. These changes in the form of his legs have resulted from the subsiding of the great tumefaction of the soft parts; all tenderness seems also to have subsided. You see he allows me to make pressure all along his shin. Again, look at his skin; you remark that the groups of shining, scaly tubercles, which were scattered over the surface of his body, and on his temples, have shrunk to a level with the surrounding skin; and two of those which had ulcerated, one on his back, and the other on his breast, have healed. Now what has caused all these remarkable changes in the space of four days? Two drachms of the hydriodate of potash. He has taken half a drachm of this salt daily for the last four days. This is precisely one of those cases of syphilis in which mercury acts as a poison; and this man was half poisoned by mercury before he applied here. The employment of the hydriodate of potash in such cases as this, is the greatest improvement which has taken place in medical surgery in modern times. This case makes the one hundred and twenty-fourth of secondary syphilis which I have so treated and carefully noted. Two years and a half have now passed since I commenced the investigation, and I have collected as great a body of facts as have ever perhaps been collected, respecting the treatment of any one chronic disease by a particular remedy. I am, I assure you, arranging, whenever I have a moment to spare, these cases, and will commence, before this month is out, to fulfil the promise, which I have long given you, of making them the subject of a series of clinical lectures on syphilis.

DISORGANIZATION OF TISSUES OF THE CALF.

Ward No. 3.—There is a disease, gentlemen, in the upper and back part of the calf of this boy's leg, to which I wish to direct your attention. You remark that there is great and deeply extending hardness in the part; that there is, what the common peo-

ple call, a "flag," that the skin has a slight purplish colour. The leg is bent on the thigh, he cannot straighten it. There is often much pain in this disease, particularly when the person stands or attempts to walk, and unless treated in one particular way, it is remarkably tedious, and often ends in the death of the hardened tissue, which falls out, and leaves a hole so large sometimes, that you could bury an orange in it. We had a similar case in Ward No. 4, a short time ago, in the person of a woman. She had been treated before she came under my care, as this boy has been treated, with poultices, and leeches, and stupes, and was not benefited, nor has this boy been benefited by a similar treatment. This affection yields rapidly to mercury, and, as far as I know, to mercury alone. The woman was materially relieved, just as soon as her gums were affected; and so will this boy be relieved as soon as the slightest action of mercury is perceptible. You see how poor and delicate a looking creature he is: you would say from his appearance that he had a very bad habit. The woman presented the same character of constitution, yet she bore the mercury well, and was extremely benefited by it. I may conjecture, but I do not pretend to say, what the disease is. I have told you its characters, and the manner in which you can cure it.

CASE OF

SMALL-POX COMPLICATED WITH HYSTERIA.

To the Editor of THE LANCET.

SIR,—If you consider the following case merits a place in your truly independent and widely-circulated Journal, I shall feel much obliged by its insertion. I have the honour to be, Sir, your obedient servant,

JOHN J. KELSO, M.D.

Lisburn, Jan. 20, 1836.

CASE.—J. F., *etat.* 19, of a stout make and sanguine temperament, enjoying up to the present attack, for the most part, uninterrupted good health. Dec. 18, 1835, I saw her, and found that three or four days since she commenced ailing, but considering her complaint as only a cold, no treatment was resorted to. She was lying on her right side, in a listless, stupid state, not caring to execute any motion, and apparently unconscious of what was passing around her. Has entirely lost the power of articulation, but appears quite sensible (in the intervals of frequent fits of delirium) of the nature of questions put to her, which she endeavours to respond to by efforts in which the whole

muscles of the trunk of the body, as it were, become roused into action, accompanied with a deep and powerful inspiration, to be instantly succeeded by a loud, protracted, but rather modulated shout. Those efforts at pronunciation are evidently teasing, if not actually painful, as she requires to be frequently interrogated before making them. Has severe headache, as evinced by the frequent application of her hands to the forehead; face flushed; skin hot and dry, and there appear a few specks on the chest, probably the eruption of small-pox. Tongue coated with a brown fur; pulse about 100, not full; stomach irritable, rejecting the ingesta, which is chiefly fluid, as there is considerable thirst; bowels constipated. The catamenia has been absent for these last two months. She was ordered a cooling mixture, with a common laxative powder.

22. The eruption of small-pox fully developed, the pustules being distinct, and rather few in number. Irritability of stomach has disappeared, and the appetite is improving. The thirst is less, pain in head diminished, but the state of lassitude persists, with a disinclination either to make the efforts at speaking, or to move herself in bed. Towards the evening there is a feverish access, and the nights are restless. Bowels preserved relaxed by cooling medicine.

26. The articulation is returning, the words, which are very imperfectly spoken, being wholly unintelligible to me, but not so to her immediate attendants. Complaints of severe pain in the lumbar region, shooting round to either groin, with a sense of heaviness in the hypogastrium. Face still keeps flushed, and the headache is occasionally violent. Tongue remains coated, but the appetite is unusually keen. Pulse about 90, rather weak. There is globus hystericus, and she cries and laughs alternately,—phenomena which set in a few days back. *Habcat emplastr. lyttae nuchæ.*

29. The pronunciation is becoming gradually more distinct and intelligible, the words being uttered at the top of an hysterical cry. There is present some debility, notwithstanding the keenness of her appetite. *Sumat Tinct. Lyttae gtt. xv ter in die. Vesicat. parv. dextr. mammae; hip-baths.*

Jan. 5, 1836. The debility has increased. Bowels have been purged from a dose of the pil. aloet. co., which she had taken. The sense of hearing is remarkably acute, and the nervous system generally in a state of considerable excitement. Nights are still restless. Has been taking bitters, wth carb. of iron, &c., for some time.

14. She is gradually, but rather slowly convalescing; some hysterical symptoms still persisting. The catamenia has not yet been restored. The tonic remedies &c. are to be continued.

Remarks.—The case just detailed I con-

sider as worthy of relation, by its affording interesting instruction, especially on two points. First, it evidences a rare example of the supervention of hysteria on the constitutional disturbance that ushers in variola. The violence of the hysteria may be judged from the fact of the complete suspension of the power of speech for the period of six days, and from its slow but gradual return to its wonted state of perfection, which it has now nearly regained. That the occurrence of this phenomenon was owing to the hysterical affection will hardly be questioned, since the existence of the latter was both then, and subsequently, unequivocally demonstrated by other phenomena that could not be mistaken; such as the wild, loud, and hysterical cry, with which she attempted to speak, the alternate crying and laughing, oftentimes immoderately, the exalted excitement of the nervous system generally, as evinced by a marked acuteness of hearing, amounting even to pain when words were uttered rather louder than usual, and an especial sensitiveness of the whole surface of the body, with globus, &c. But the question here occurs, whether the development of the hysteria is to be attributed to the pyrexia of the small-pox, or to the amenorrhœa, which, as has been seen, had existed for a period of two months. That the hysteria did not at least immediately originate in irregularity of menstruation is pretty evident, from the circumstance of the derangement of the uterine function persisting during even established convalescence. Its development may rather be referred to the fever, the system possibly having previously taken on the predisposition from the above, in conjunction, perhaps, with other causes. But although the vast importance attached to deranged uterine action as an exclusive, or even a chief, origin of hysteria, is justly exploded, it may still be considered as acting, to say the least, not altogether an unimportant part in its excitement as a predisponent cause. Hence its regulation, if possible, in all systems of treatment, should form, as it has formed with all enlightened practitioners, an indication, in every case, of primary moment.

Next, it adds another instance to the too many that are already on record, that vaccinia does not ensure a complete exemption to the system from a subsequent attack of variola. In proof of the genuineness of the variola in this case, notwithstanding the presence of a distinct vaccine indentation on one of her arms, I may simply enude-
 rate the intensity of the febrile commotion that ushered in the eruption, the regularity of the progress of the latter to maturity and decline, coupled with the fact of each vesicle exhibiting the characteristic central depression. Although it must be confessed that in this case the eruption was not very extensive and distinct, cases are not unfre-

quently observed to run their course, where vaccination was never practised with an equal degree of mildness.

It may not here be out of place to state, that for the last year, and better, small-pox has prevailed epidemically, to an alarming extent, in Lisburn, and in the country for many miles around it, attacking indiscriminately the vaccinated and the unvaccinated, the old and the young. It exhibited itself chiefly under the confluent form, and the number of fatal cases were uncommonly large, occurring, principally, as they did, in those who had never undergone vaccination. It was observable, too, that in all the cases which were vaccinated, and were afterwards attacked by variola,—and these were a considerable number,—it ran its course both more mildly and speedily, the mortality being comparatively trifling, the vesicles still presenting their distinguishing characteristics. But from the fact of vaccinia being thus found inefficient, in all cases, as a preventive to infection, the common people have considered the having recourse to vaccination as useless, and the opinion has extended, and is extending, propagated, as it is, in particular places, by some of its officious, if not influential members, that safety alone resides in inoculating with the variolous virus. Thus in some parts inoculation has been practised rather extensively; and although, generally speaking, the result is more favourable, the disease passing through its course more mildly, yet instances of a more fatal termination are by no means rare. Besides, the practice cannot be too much reprehended, as it not only tends to abuse the public mind against what yet must be considered as a valuable substitute, but operates injuriously on society, by the propagation of a dreadful, and we would fain have hoped, a banished scourge. Viewing, however, as I do, vaccinia as an admirable and still efficient security against variolous infection, under particular circumstances, it may not be improper to mention what those circumstances are; and in doing so I only reiterate an opinion, subject, so far as my experience goes, to no exception, not lately advanced, and which has, of late, become rather popular, that when considerable febrile commotion is excited in the system, with inflammation in the course of the absorbent vessels and glands, in the inoculated extremity, and the evolution of pustules, either round the original vaccine one, or on other parts of the body, (phenomena which fully demonstrate that the system has been influenced by the vaccine lymph.) the most implicit reliance may be placed on its adequacy as a preventive mean against all subsequent infection. It were useless to search after any other sufficiently valid test of the genuineness of vaccine lymph, than its demonstrable tangible effects on the living economy.

With regard to the treatment of the case, there is little worthy of remark beyond the fact that, as no remedies of an active nature, for combatting the hysteria, could be had recourse to during the progress of the small-pox, it was left to take for a time its own course. This was the more to be regretted, on account of the melanina appearing when the eruption was about beginning to decline, as this would have been the proper time for resorting to those remedies best calculated to elicit the catamenial discharge, the accomplishment of which would have proved, doubtless, an important preliminary step towards a cure; but the taking advantage of nature's effort, at that time, by any active treatment, would hardly have been justifiable. Subsequently, considerable debility set in which demanded a tonic system of treatment; and as the restoring the healthy tone to the system was considered the best emmenagogue, few remedies pertaining to this class were resorted to. The practice of irritating the mammae, recently so much lauded as an important means of eliciting the menses, through its acting sympathetically on the uterus, proved ineffectual; but at the same time it is right to state, that owing to the debility then present perhaps it had not a fair trial.

RHEUMATISM FOLLOWING GONORRHOEA.

To the Editor.—SIR, my attention having been drawn to a statement published in THE LANCET of Saturday, January 16th, respecting gonorrhoeal rheumatism, I beg to say that I think this disease does not in all cases arise from the administration of copaiba. There is at present a man in the *North-London Hospital* labouring under this disease, and who has been there for the last two or three weeks, and on my questioning him, he strongly denies ever having taken any of the above medicine. The treatment adopted by Dr. Elliotson in this case, consists in the exhibition of hydriodate of potassa, with manifest advantage. The most peculiar symptom in this case is a severe pain in the soles of the feet. The following is a short account of the symptoms peculiar to this form of disease, extracted from some rough notes taken at Dr. Elliotson's lectures at the University, when on the subject of rheumatism. "Rheumatism is very much predisposed to by gonorrhoea. This sort of rheumatism always affects the feet. It may affect the knees and hips also. It is also a very obstinate form. With this rheumatism there are generally attacks of superficial inflammation of one or both eyes. It is not iritis, and it is not purulent, but it is attended by copious watery secretion. Some persons never have gonorrhoea without this secretion."

There have been several other cases of this form of disease in the hospital during the last year, all of which have been successfully treated by the hydriodate of potassa. Should any other cases occur, I shall not fail to make inquiries, the result of which I will forward. I am, Sir, your obedient servant,

J. B. SAMUEL,
Student N. L. H.

Vauxhall, Jan. 23, 1836.

MEDICAL AID FOR THE SICK POOR.

PROPOSAL FOR ITS SUPPLY ON EQUITABLE PRINCIPLES.

To the Editor of THE LANCET.

SIR,—Having been lately requested to sign a protest of the general practitioners in medicine of this part of the country, against the misrepresentations of the Poor-law Commissioners,—which, although in no way interested, except as the advocate of justice and humanity, I had great pleasure in doing; and having for many months past listened to endless discussions, and read an infinity of remonstrances, and letters, and complaints on the subject, I still think that the main points and strength of the case have been overlooked, and therefore should you think this letter of an impartial bystander worth publication, I beg you will give it a place in the first spare corner of THE LANCET.

Every one will admit that our Government must have been actuated by the laudable desire of ensuring proper medical attendance to the sick poor of the country, and it remains to be seen whether their agents, the Poor-law Commissioners, have adopted the proper steps for effecting that national object, or whether they have not, on the contrary, sought to slur over the calls of true humanity, and, as I shall presently show, by practising on the fears of the established medical officer, driven bargains with him, and, on degrading terms, exacted an amount of duty which never can be rendered with the effect sought to be obtained, because in their rage for union and centralization, they have in many instances removed the sick poor as effectually beyond his eye, and out of his reach, as if the object had been to deny them all medical assistance whatever.

It has ever been easy to be charitable at the expense of others, and the game has too often been played of seeking popularity and applause, to the prejudice of justice. When the Poor-law Commissioners therefore claimed credit for economical reform, by advertising for the lowest tenders, and calling up the inexperienced needy adventurer from the schools, in want of a place, to un-

derbid the established practitioner who had long been in charge, they handed over the sick poor to serve the purpose of the former's unprincipled speculation, or held him up in *terrorem* over the latter, with the view of imposing conditions upon him which he never could execute in fairness either to the unfortunate paupers or himself, but which, in order to preserve the practice on which he subsisted, he found himself obliged to submit.

This surely was intimidation and not justice—far less could it come under the denomination either of charity or humanity, and as it must be the aim of every parental government to protect all classes of its subjects, the numerous medical practitioners throughout the land have a right to invoke its protecting shield against their present oppressors, and this can be extended to them effectually, only in the way of a national enactment, providing medical attendance in every parish for all the paupers, whether sick or well, in the list, on equitable terms, at so much annual cost per head, and then the Commissioners, by selecting and appointing the best, instead of advertising for the worst, may exercise, and under proper regulations enforce, that humanity to which they were so falsely laying claim.

As a contract, take it in what way you will, always implies eventual gain to the contractor, every system of tender and underbidding must be bad, and in the long run the sick poor must be the only sufferers. The system I advocate, were it fairly entertained by the legislature, would be national, humane, and just to all parties. It has for ages, under certain modifications, been practised in the army and navy. It was, as I have witnessed, executed with the best effect amongst all communities of negroes throughout the West Indies, and I can conceive no good reason why, *mutatis mutandis*, it may not be brought into operation amongst the pauper population of Great Britain. One mighty advantage would be the simplification of accounts, of regulation, and of duty. All would be comprehended, without confusion or dispute, under one principle of action; and if the reciprocity of compensation and duty be justly poised, the sick poor would be duly cared for, and the medical attendant not degradingly, because not unjustly, rewarded. Any other plan than this must be fraudulent, as laying claim to charity, and that too without effecting the object, at the expense of the medical profession, while it cannot fail to involve the members of this last in perpetual contest with the poor-law authorities; they are seeking to impose, and the other to avoid, impossible duties, and all to the prejudice of the poor. This would be clear and intelligible to every one, and should it appear so to the profession, I hope they will arise, as one man, to seek the protec-

tion which its enactment would afford. I do not here enter into details to prove the foregoing, or to show that the best established practitioner of every parish, from his knowledge of the pauper's character, and the responsibility for his own, must ever be the fittest in the first instance, and should never be employed out of its bounds, or at least beyond his beat, for the sick poor require to be protected against neglect, as much as their doctor against oppression; but I am ready to do so should my statements be disputed.

Having, of late, avoided the topic, and ceased to read upon this tiresome subject (for nothing is so tiresome as the reiterated language of unredressed grievance), I really cannot tell whether the above proposal may not already have been laid before the public through some other channel; if it has, this letter will be superfluous; but if otherwise, its publication in *THE LANCET* may probably, in some degree, serve the cause of the profession. I have the honour to remain, Sir, your most obedient servant,

W. FERGUSSON, M.D.,

Inspector-General of Hospitals, H.P.

Windsor, Jan. 20, 1836.

MEDICAL POOR-LAW CONTRACTS.

LETTER FROM MR. RUMSEY.

To the Editor of *THE LANCET*.

SIR,—I have perused the leading article in *THE LANCET* of Saturday last relative to the mode of making medical contracts in the Poor-Law Unions, and beg, in reply, to assure you that much as I should rejoice to see some decisive step taken to bring the present state of parochial medical attendance under the notice and investigation of Parliament, I should not feel justified in coming forward as you propose, to call a public meeting of the profession in London.

My reasons are as follow:—

1st. In my official capacity, as Secretary to a Committee consisting of eleven members of the *Provincial Medical Association* (residing in eight different counties of England and Wales). I could, of course, do nothing without their joint approbation and direction.

2nd. I am quite uncertain whether their approbation to such a measure would be obtained, or whether they would consider themselves authorized to act in a manner not at all contemplated in their original appointment, which was for a specific object, viz. to report on this matter at the next anniversary of the Association.

3rd. It is also very doubtful whether a public meeting in the metropolis would ascertain the feeling of the great body of

country practitioners, very few of whom could attend, and still fewer could remain long enough to enter fully into the subject, which requires a particularly careful and calm discussion.

My own opinion with regard to the best course to be pursued on the occasion is, that associations of medical practitioners should forthwith be formed in every county or district, similar to those in Berkshire, Buckinghamshire, Sussex, the Wealds of Kent, and East Kent,—that meetings should be held by each association, for collecting evidence relative to the working of the present system; for devising the most effectual means for a remedy; and for taking immediate measures to bring their views before the consideration of Parliament, either by petition, or by direct communication with their local representatives. It might also be desirable for each association to appoint one or two *deputies*, who might meet in London, and who, being fully prepared for the discussion, might agree, *with effect*, on some plan to be submitted to the Legislature.

However, as I am desirous that your recommendation should have full weight, I have written to all my colleagues on the subject, and if anything should transpire from our consultation worthy of your knowledge, I shall not fail, with your permission, speedily to inform you of it.

As the appeal to me was public, perhaps my reply should likewise be so. I have the honour to be, Sir, your very obedient servant,

H. W. RUMSEY.

Chesham, Feb. 1st, 1836.

CONDUCT OF THE APOTHECARY EXAMINERS OF MR. SMITH.

To the Editor of THE LANCET.

SIR,—I trust the interest which you have always shown in the cause of medical students generally, and in the case of a late rejected candidate for the apothecaries' license, especially, will extend to an early insertion of this letter, as it touches very materially upon one point in the report of his case.

It was stated by the Chairman at the meeting at the *Crown and Anchor*, and again reported in your journal, that in the course of the examination of Mr. Smith, the indentures of the candidate were produced by the Secretary, Mr. Watson. I presented myself on the same evening as the gentleman alluded to. The proceedings commenced by each signing his name, testifying that all the certificates he had produced were correct. After this, and previous to the commencement of any one of the examinations, my

indentures were returned to me, and I immediately left the table. Thus, having preceded Mr. Smith, I did not see whether his were returned to him; but from others who have passed the Hall, and, among those, one who presented himself on the same evening, I have ascertained that their indentures were returned after the same manner as mine. Now in my case, as in others, my examiner could not have perused my indentures a second time, unless I had voluntarily produced them, or Mr. Watson or some one else had picked my pocket while my attention was so very anxiously engaged; and in that case one or two circumstances must have taken place: either the candidate or his foster tutor, Mr. Meade, has made an incorrect statement,* or the indentures must have been retained specially for the purpose of their production in the manner described. If the first suggestion which I have thrown out be satisfactorily refuted by Mr. Smith himself, and he certainly ought to notice it, it will warrant the charge that his rejection was *premeditated*, and that animosity was entertained towards him by the examiners, ending in an act of foul injustice. If Mr. Smith vouches for the truth of the statement, the Secretary to the Society of Apothecaries will afford, as a matter of course, an explanation of this most extraordinary affair. I am, Sir, your obedient servant,

INVESTIGATOR.

London, Jan. 28th, 1836.

MEDICAL MAGISTRATES.

SIR,—As the champion of the general practitioner, I address myself to you on a subject which interests our profession. I understand that the Lord Lieutenant of this county refuses, most preposterously, to hear of any application made to him on the part of any member of the medical profession, for an appointment as magistrate. Has his Grace's elevation precluded him from knowing that this class of his Majesty's subjects is as well educated and more generally informed than most others, and that their conduct, their habits, and their means of acquiring a knowledge of mankind, are not excelled by those of any other? Upon what ground, then, does his Grace object to the medical practitioner? We know, for we have had many examples, that any illiterate retail trader whose success in business has enabled him to become possessed of a freehold property of the value of 100*l.* per annum, professing *Tory* principles, has no difficulty of mounting the bench.

* The latter gentleman has been engaged as private tutor sufficiently long to be well aware that the production of the indentures could be only compatible with great irregularity in the customs of the court, and I certainly ought to have commented upon the statement at the meeting.

An old law which excused medical men from serving on juries, and performing the duties of parochial offices &c., and which was then intended as a boon, has of late years been converted into a reproach by the ignorant. The office of coroner was formerly frequently held by the medical practitioner.

I am very happy to see by the late municipal returns that many of the towns have appointed medical men as councillors; and I trust that, ere long, our body will take that station in society, and assume that importance, to which its intelligence and moral character entitle it. I am, Sir, yours &c.

MEDICUS.

London, Jan. 23, 1836.

PETITION FOR REMUNERATION AT CORONERS' INQUESTS.

To the Editor of THE LANCET.

SIR,—I take the earliest opportunity to inform you that at a Committee meeting of the *Berkshire Medical Association*, held this day at the *Reading Dispensary*, the following petition was prepared for presentation to the House of Commons. I am directed to request that Robert Palmer, Esq., will do us the honour to present it, and also to furnish a copy to all the members in the county, with an earnest solicitation of their support. I have the honour to be, Sir, your obedient servant,

GEORGE MAY.

Reading, Feb. 2, 1836.

To the Honourable the Commons, &c.

The Petition of the undersigned Medical Practitioners resident in Reading and its vicinity, and in other towns and villages in the county of Berks,

Humbly sheweth,

That your Petitioners have been at all times willing to further the due administration of justice in their attendance on Coroners' Inquests.

That the duties which thus devolve on your Petitioners are highly important and responsible, requiring the possession of extensive knowledge, and the devotion of much time and anxious labour.

That your Petitioners are advised and believe, that the law in its present state does provide a remuneration for their services at Coroners' Inquests.

That your Petitioners respectfully appeal to your Honourable House, with the temperate but earnest language of complaint and remonstrance, humbly beseeching you to supply a remedy against the injustice which they thus suffer, and to enact the award of such equitable remuneration as in your wisdom may seem meet.

And your Petitioners will ever pray, &c.

ALDERSGATE SCHOOL OF MEDICINE.

LETTER FROM DR. CUMMIN.

To the Editor of THE LANCET.

SIR,—My name having been very unceremoniously introduced into your last number by a writer signing himself "An Attendant at the Aldersgate-street School," you will perhaps allow me to set this person right with respect at least to his principal misstatement.

The fact is this. When I quitted the theatre on Wednesday last, after lecture, found in the museum a student who said he wanted to put a question to me, and hoped would answer it. I assented. Upon which, to my surprise, he began with, "Understanding, Dr. Cummin, that you are part editor of the *Medical Gazette*, in which an article has appeared"—I at once cut short the speaker to demand what right he had to address me in that form; I pointed out to him the impropriety of his conduct, and added that it was highly impertinent in him or anybody else to impute to me the authorship of any article appearing without any signature in the *Medical Gazette*.

Such was the whole amount of what passed; Mr. Skey and Mr. Furley, who were present, can vouch for the truth of what I state. The latter part, consequently, of your anonymous correspondent's letter, beginning with, "It is but just to Dr. Cummin," &c., is totally unfounded—pure and gratuitous fiction. I am, Sir, your obedient servant,

W. CUMMIN.

February 1st, 1836;

24, Great Russell Street, Bloomsbury.

Dr. Cummin having submitted to our perusal the preceding letter, we can guarantee the perfect correctness of the statement which it contains.

F. C. SKEY.

EDWARD FURLEY.

Aldersgate School of Medicine;

February 1st, 1836.

THE LANCET.

London, Saturday, February 6, 1836.

Two or three weeks since we were instructed to believe, by the hirelings of the corruptionists, that the draft of the charter of the new Metropolitan University was in a state of forward preparation, and, more-

over, that the preliminary labour had thus far been executed by the enemies of medical reform. The charter was to be out in a few days, and its machinery was to be set in active motion by the wily fabricators, and the partisans of the two chief medical corporations. Yet there is no charter, and there is no person beyond the precincts of the Privy Council Chamber, who can obtain a glimpse of such a document. Let us hope, then, that discussion, exposition, and a little salutary agitation, have been productive of some advantages to the community. If this matter had been left to be settled quietly in holes and corners by the intriguers, the charter long since would have received the sign manual of the King, and a precious charter in all probability it would have been. Not that the Ministers have no desire to do justice to the public in this transaction, but because it is quite clear, from what has already transpired, that they were not acquainted with, or had not sufficiently investigated, the laws which the new institution was designed to effect.

Anticipating that some such obscurity of the intellect prevailed on this subject in the Cabinet, we insisted on the production of a draft of the intended instrument, and we now unhesitatingly contend that the prerogative of the Crown with respect to charters, is grossly abused, and brought into public odium, when it is exercised secretly, in consummating measures which affect the general interests of the people. If nothing wrong be intended, whence the necessity for concealment? But the mere endeavour to carry on the work secretly is proof, *a priori*, that something wrong is intended. If Charters are to be privately constructed, why also are not Acts of Parliament? In both cases there is an equal reference to the principles of legislation, as well as to the details by which the laws are to be executed.

The monopolists of our colleges must be sorely perplexed on finding that the predictions of their hireling tools have not been

verified, and they may now, perchance, if they be not totally blind, discover, that in the very hesitation of the executive, is to be found one of the best proofs of the honesty of the Ministers. It is now sufficiently evident that the advisers of the Crown have not been entrapped, whatever may have been the number of snares set for their discomfiture and betrayal. At all events, it will be found, ultimately, we apprehend, that the opponents of instituting a liberal University in this metropolis, will not have the misfortune to be the chief labourers in the work. Even if their evil genius have been consulted in the design, their plans, we can assure them, *will not be adopted*, so that neither from their heads nor their hands will any auxiliary aid be solicited or obtained.

Although we were told, again and again, that the charter was near its completion, yet no hint was given of what would be its conditions, and the friends of the new institution were exposed to the incessant torture of conjecturing its contents. There was much of discretion manifested in this studied silence, experience having but too long proved that arrangements in medical government which were suited to the feelings and practices of our two detested medical colleges, would at once be spurned with indignation by nineteen twentieths of the profession. A popular liberal government would hardly trust, in so important an undertaking as that of founding a new University, the ramp of that most intolerant faction, which, even now, by its prejudices and bigoted conduct, is daily throwing an additional burden of degradation on the governing councils of the Colleges of Physicians and Surgeons. Throughout the progress of the discussion on the new project, we have not for a moment doubted the integrity of the CHANCELLOR of the EXCHEQUER and his colleagues. But it occurred to us that they stood in need of some wholesome advice. It was imagined that they would start the new institution with

precipitancy,—that a sinister influence might establish and work out the governing principle, and the dangers were magnified in our view by supposing that the well-meaning founders commanded but a very imperfect knowledge of medical law, and of the multifarious circumstances which are connected with the existing chartered corporations. The contrivers in this instance, on both sides of the question, have appeared to imagine that it is as easy to manufacture and set in motion a new metropolitan University, as to puff out a soap-bubble, and float it in the air. The minds of these persons, however, it is evident, have not been applied to the most intricate or weighty parts of the subject, or, possibly, the most active of the advisers of the CHANCELLOR of the EXCHEQUER have consisted of two descriptions of persons,—one anxious that the institution should be imperfectly founded, in order that it might experience a speedy downfall,—the other, less anxious regarding the general interests of science and the community, than for the success of one or two favourite institutions. Placed between the clashing views of individuals whose minds were thus biased, the Ministers have not had an easy duty to discharge. The delay, therefore, which has occurred in executing it, must induce every unprejudiced person to believe that they would not willingly lend themselves to forward the sinister schemes of either faction. We still hope and believe, therefore, that the advisers of the Crown will go straight forward in their undertaking, fearlessly, boldly; disregarding the threats of enemies on the one hand, and the interested entreaties of friends on the other. A more glorious opportunity for founding a national institution, dedicated to literature and the sciences, never offered itself to a body of enlightened statesmen, and as the enemies of reform have conceded a principle, difficulties there can be none where there is found comprehensiveness and vigour of intellect.

We are presuming, however, that there

is honesty of purpose, that there exists on the part of the executive authority an ardent love for the diffusion of knowledge, and, in the pursuance of that great and divine object, that there shall be manifested a display of contempt and defiance towards every individual who presumes to occupy a position which is detrimental to the hopes and prospects of the majority of the nation. If the new institution be based upon just principles, it will not so much be the University of London as the University of the Empire, whose inviting portals will receive without distinction the sons of genius and intellectual industry. If it be designed to give an impetus to the progress of knowledge, why, we ask for the hundredth time, should its utility be lessened, its splendour be clouded, by the imposition on students belonging to certain schools, of a peremptory curriculum? The system of education should remain as free as the air; and the certificate system, as it is at present carried into operation between the schools and the colleges, ought to be annihilated for ever. What is it, in fact, but a tax which operates prohibitory of honours, of fame, and of fortune, against the natural talents and prospects of the poorer members of society? This question should be answered unrestrainedly by every advocate of the certificate system, and if the answer contain no refutation of the principle for which we contend, let us have an institution which shall be devoted to the interests of the nation, and not dedicated to the sordid interests of a monied aristocracy.

IN THE LANCET of last week, we inserted a note at page 727, signed "An Attendant at the Aldersgate-Street School," in which reference was made to the alleged disclaimer of a Dr. CUMMIN, that he was in any way connected with the trashy thing printed every week, called "The Medical Gazette." A note will be found, on the same subject, in the present Number of THE LANCET, from Dr. W. CUMMIN himself. In this last

production, there is a contradiction of a portion of the statement which was contained in the one first published. But what is to be inferred from the remainder of the epistle? We put the question, in order that it may be answered by the party who is most deeply interested in the affair. Before, however, any reply can reach us from that individual, it is our bounden duty to inform Dr. W. CUMMIN, that it has repeatedly been stated to us that he is the coadjutor of MACLEOD in printing the attacks which systematically appear in "The Medical Gazette" against the general practitioners of this country. Out of mere mercy to Dr. W. CUMMIN, and from a dread of subjecting ourselves to the reproach consequent on giving currency to an incorrect accusation of so serious a character, we have hitherto refrained from coupling the name of CUMMIN with that of MACLEOD in the work of slandering—perseveringly and systematically calumniating,—the general practitioners of medicine in this empire. Every man of honourable feeling would shrink, instinctively, on hearing that it had been rumoured that he was the writer of the articles in, or was in any way connected with, the editorial department of so infamous a work as "The Medical Gazette." Even MACLEOD, it will be recollected, sent, whiningly and cringingly, to the Editor of THE LANCET, protesting that he had ceased to be the hack of the booksellers in Paternoster Row. Even RODERICK MACLEOD hastened to rid his pure character from the imputation of being the fabricator of a journal, in which, at the command of employers attached to the "recognised" hospitals, attempts had so long been made to hold up to derision and scorn the professional character of the great body of English medical practitioners. MACLEOD knew, and had long been made to feel, that he had, on many occasions, contrasted the "eminent names" of writers who had figured in the columns of the subscription journal, with the comparatively "unknown," but not less re-

spectable names, which were attached in the pages of THE LANCET to many of the best medical productions that had ever been printed in the English language. In the eyes of the Editor of "The Medical Gazette" (the poor devil was whipped to his work), a knowledge of the science of medicine and surgery was confined to "hospital" physicians and "hospital" surgeons. Like his friend and colleague BENJAMIN BRODIE, he treated general practitioners as a "subordinate" class of men, and—not stopping there,—with a malignant cowardice never equalled in the annals of literary or controversial turpitude, finding that he was incapable of coping, in arguments and statements of facts, with the advocate—many years the only advocate—of general practitioners, the writer of the editorial articles in "The Medical Gazette" became a moral assassin, and insinuated a charge against the character of the advocate of the general practitioner, which a malignant and cowardly spirit would not allow him to make openly, and under circumstances of just and honourable responsibility. There continued the despicable slanderer, whoever he may have been, behind the shield of, as he hoped, an impenetrable ambush. The disgust and indignation, however, of the maligned majority of the profession, took a direction which prompted RODERICK MACLEOD to assert that he was no longer editor of "The Gazette." In a moment of virtuous regret, or of Scottish prudence, he tried to escape from the responsibility of the connection. Suddenly struck with horror at his position in society, he retreated from the bar of public scorn, with as much precipitancy and rapidity as he flew to the Police Magistrates of Marlborough-street, from the horsewhip of Mr. MACHISTIE. Whether, in denying his connection with "The Medical Gazette," the statement of RODERICK MACLEOD was true or false, it has not been necessary, from that period, to make his conduct and character the subject of more than an occasional curatory remark. Who

ever may have been the writer of "The Gazette," whoever may have been guilty of the baseness and cowardice of attacking the private character of the Editor of *THE LANCET*, because that Journal was strenuous and persevering in support of the rights of thousands of English surgeons against the encroachments of the Colleges, and the insults offered to them by the functionaries of the Hospitals, the slanderer succeeded in destroying his own; at any rate, of causing the bare suspicion that any man could be the author of so much infamy, to be converted into the means of his own professional ruin. When RODERICK MACLEOD ceased to be the Editor of "The Medical Gazette," we know not; but we believe that the most that can be said of him at present is, that he has the opportunity of administering "bread pills" to some of the patients of *St. George's Hospital*. He is *one* of the sufferers in that establishment. His fate is redolent with instructive warning.

But to return to Dr. W. CUMMIN. The contents of his note, we tell him frankly, are of a suspicious description. He has taken a step which requires that he should advance farther, or sink back at once into the abyss of odium in which the report of his being connected with "The Medical Gazette" had thrown him in the minds of the students. There is no escaping from the dilemma but by making an unqualified declaration that he has no official connection with the editorial department of that production. Unless he be in a condition to publish such a disclaimer, he will probably spare himself many years of anxiety and fruitless toil, by at once taking his departure from this metropolis, and returning to his native country. Neither the soil of England, nor the feelings of the bulk of his professional brethren, will be found at all congenial with his professional pursuits and interests. We trust, therefore, that the next communication of Dr. W. CUMMIN will be sufficiently expurgatory of

the stain which still lodges upon his reputation. Already he seems sensible that the bare suspicion of his connection with the editorial office of "The Medical Gazette," demands the substantiation of a contradiction offered under his own name, by the testimony of two witnesses. He has already made a true estimate of what must be the certain consequences of a connection with the pestiferous and odious journal in the pages of which the signs of cowardice, falsehood, and malignity, have been regularly traced by the pen of a concealed low-minded slanderer.

In the notices which have appeared in the journal so frequently named in the course of the foregoing remarks, of the great meeting of medical students held at the *Crown and Anchor*, the consistency of that work, in its love of calumny, is strikingly apparent. Not content with falsifying the conduct of the gentleman whose temperate and admirable behaviour conferred a dignity on the deliberations of that assembly, which could not have been adequately derived from any other source, the maligner of the students, the defender of the unjust conduct of the Apothecaries' Company, the systematic advocate of the abuses of our hospitals, and the corruption of our corporations,—this contemptible slanderer of the bulk of the English medical profession, must necessarily display his viperous poison in making an attack upon Mr. LISTON, only because that distinguished surgeon was present at the meeting, and, by his presence there, showed that he sympathized with the insulted students, and was desirous that their privileges should be placed upon a just and secure footing. In taking part with the students, Mr. LISTON has committed a heinous offence, and he must therefore be made the subject of a certain portion of vituperation. Accordingly, amongst the imputations which are thrown out against the purity of that gentleman's motives in attending the meeting, is one which charges

him with having been actuated by a fellow feeling with one of the aggrieved parties. "Was there," says the slanderer, "any kindred grievances to be complained of? Had there been a recent rejection, a double one, of a candidate in Lincoln's-inn-fields, to irritate the feelings of the "celebrated surgeon" of the North, and all at once to drive him into the ranks of "medical reform?" In the outpouring of his envy and malignity, the hired scribe has forgotten that the meeting did not concern a "recent rejection" in Lincoln's-inn-fields, but one at Rhubarb-hall. And from whom did he obtain his information relative to the "rejection" at the College of Surgeons? Why does he conceal the facts? *Why?* Because a simple statement of them would overwhelm his employers with disgrace. True, a student was lately rejected at the College of Surgeons, after two pretended examinations. And under what circumstances? The young gentleman had been upwards of six years in the profession, and his time had been thus bestowed;—

He was five years the private pupil of a distinguished hospital-surgeon in Edinburgh.

He had been nine months dresser in the Royal Infirmary of Edinburgh.

During nine months he was the clinical clerk of the surgeons of the Royal Infirmary.

During eighteen months he was physician's clerk in the same institution.

He regularly attended all the medical classes in Edinburgh, and constantly dissected during long periods in Edinburgh and London.

This gentleman was rejected. Because he was not qualified? No. But, as we believe, and probably as the profession will believe, because he had been the private pupil of Mr. LISTON, and thus the persecuted student was made the medium of attacking the character and reputation of the teacher. The pre-eminent qualifications of the candidate are well known. No

doubt can be entertained of his perfect capability to undergo a fair and impartial examination. Nay, we can prove that one of the Examiners at the College of Surgeons, who was present on the occasion in question, has since declared that the young gentleman "had fairly mastered his examination." Yet he was subjected to the pain and mortification of a rejection. If the examiner who was the author of the cruelty, be exulting in his success, we tell him that the termination of his triumph will be the infliction of a lasting disgrace on his character, if he be not instrumental in procuring for the rejected student a public examination before an impartial public tribunal. SUCH A SCRUTINY IS NOW CLAIMED BY THE CANDIDATE, AND WE ARE AUTHORIZED TO MAKE THE DEMAND PUBLIC. The candidate is ready, willing, and solicitous of proving that he has been the victim of injustice, and all eyes will now be directed towards the parties who are stigmatized with being his persecutors. Had the young gentleman been a private pupil of any one of the surgeons either of *St. Bartholomew's Hospital*, *St. Thomas's Hospital*, or *Guy's Hospital*, had he been clinical clerk to either of those surgeons, or had he produced an enormous roll of "certificates" from the surgeons of either of those hospitals, who can or will believe that he would have been rejected? Had he been placed under the circumstances just stated, some eight or ten very simple and ordinary questions would have been asked, and there the scrutiny would have terminated; but in the case of this young gentleman, a thrust was to be made at Mr. LISTON, whose appearance in the metropolis has disturbed the nerves of the whole of our "consulting" surgeons, with the exception, probably, of Sir ASTLEY COOPER and Mr. WARDROP. The fame of Mr. LISTON has already extended throughout Europe, as an operator and a pathologist, and, placed as he was, at the moment of his arrival in this metropolis, by his previously-established fame, in one of

the most prominent places in the first rank of his profession, no art, no contrivance, no misrepresentation, of which the monopolists can be the authors or the inventors, can have the effect of checking the course of his brilliant and successful career. On the contrary, the attack which has been directed against him in the person of his pupil, is an acknowledgment of his reputation and power. It is a concession which the force of genius has extorted from prejudiced and tainted minds, and were it not for evidence of this undoubted and unquestionable character, we might be incapable of judging to what extent or to what purposes the minds of the hospital surgeons of this metropolis had been excited by the honourable appointment of Mr. LISTON to the office of surgeon in the hospital of the "University of London."

In publishing the letter of Mr. RUMSEY, (page 747) we have only to remark that his plan would be perfectly unexceptionable were there time for carrying it into execution. We hope, therefore, even yet, that either himself, Mr. YEATMAN, or some other gentleman who has devoted his attention to the subject, will act upon the suggestion which was submitted to the profession in the last number of THE LANCET. It is quite certain that there is not now sufficient time to form county associations, whose opinions could be brought to bear with sufficient effect on the decisions of Parliament. If the meeting were convened in the metropolis, Mr. RUMSEY would find that many hundreds of medical practitioners would be present. It is a question in which the entire medical body takes a deep interest.

The disciples of HAHNEMAN are becoming as numerous in this metropolis as, and not more so than, those of the late wild-headed EDWARD IRVING, and, apparently, from the same cause, that is to say, the

author of the scheme obtains the sanction of his dupes to some of his nonsensical hypotheses, through first seducing their assent to some common-place principles which all admit to be incontrovertible. Whatever is new in the homœopathic system evidently is not true; and whatever is true, may be found in medical writings from the days of HIPPOCRATES to those of SYDENHAM, or from the time of SYDENHAM to that of CULLEN.

Since writing the above remarks we have received the following statements from one of our reporters. We beg those members of the profession who may think the matter worth a moment's consideration, to remember that the "new" light is not that of homœopathy simply. The proper name for the mania is HAHNEMANISM.

The discussion at two of the metropolitan medical societies at their last meetings have ended with remarks on the subject of Hahnemanism, Dr. Uwins bringing it forward in the Westminster, and Mr. KINGDON in the London Medical Society. Both those gentlemen seemed to think that it would be well for the profession to inquire into the merits of the new doctrine, particularly as "a number of influential merchants and others in the City of London had become advocates of the system. One of them had lately experienced some relief in a cutaneous affection, from adopting the treatment of a German doctor, and had wholly dispensed with the attendance of the surgeon to the family, because that gentleman declined to treat the children on the homœopathic principle!" Mr. KINGDON related other cases of a similar kind. He certainly considered, he said, that it would be proper, from the influence the system had obtained over the minds of many very intelligent men in this metropolis, to prove its merits. We have heard that "the new system" is a subject of common talk "on 'Change." Dr. Uwins states that he was convinced that Dr. QUIN, one of the Hahnemanists, was not likely to be led away by imagination or charlatanic views. He was also in consultation with Dr. DARLING a short time since, when that gentleman ordered three minims of the liquor ammoniæ acetatis in a mixture for a child, asserting at the time that he had found it exert more diaphoretic power in such doses than in larger.

It was also stated by a Member of the London Medical Society that several of his patients had placed themselves under Hahnemanists, and that he knew two physicians of eminence who, after being unsuccessful in the treatment of several cases, recom-

mended their patients to try the homoeopathic system. Considerable amusement was afforded by the statements of several members who considered the system "fudge." But several treated the subject very seriously.

A Manual of Experiments Illustrative of Chemical Science, systematically arranged, &c. By JOHN MURRAY, F.S.A., F.L.S., F.H.S., F.G.S., &c. 3rd Edit. London, Highley, 1836.

THE author of this little work is a kind of admirable Crichton in his way; there is no article of the encyclopædia that he has not written upon. Appended to the volume before us are notices of not less than fifteen treatises by the same author on subjects relating to chemistry, natural history, experimental philosophy, medicine, navigation, theology, and the inferior mechanical arts!

The *opuscule* itself is an epitomized epitome of chemistry, a selection of the plums from the pudding, a means by which, without the pains of thinking, any idle fellow may attain a sufficient modicum of practical chemistry to astonish young ladies and little boys. Every nanum, happy in the possession of a son with an uncommon genius for the explosion of squibs and crackers, and the ignition of phosphorus, cannot do better than present him with this important volume.

NEW OPERATION TABLE.—Those who are familiar with the scenes of confusion, and know the want of system, which daily prevail in the majority of the operating Theatres of the Metropolitan Hospitals, will feel much gratified by inspecting an apparatus, which has been contrived by Dr. VEITCH, a model of which is now at the Admiralty. In conducting surgical operations, we generally observe either a most ostentatious and ill-timed display of instruments, or an affectation of simplicity of means for accomplishing the intended purposes, so that when any unforeseen accident occurs during an operation, the requisite instruments are not at hand. The ingenious contrivances of Dr. VEITCH obviate all those difficulties, combining in a small space not only a Table which is well adapted for all surgical operations, but having underneath the table, and invisible to the patient, a set of compartments sufficient to

contain every kind of surgical instrument. The table is so contrived that the head of the patient can be elevated to any angle, and its length may be altered according to the height of the patient. The compartments are each marked with their particular contents, so that any assistant can at once supply the operating surgeon with whatever instrument he may require. Although Dr. VEITCH, who is an experienced Navy-Surgeon, has designed this admirable table for the use of surgeons of the Navy and Army, yet it is equally applicable to all public Hospitals, and may be most advantageously possessed by all medical gentlemen in extensive general practice.

HOSPITAL SAMARITAN SOCIETY.

"There has existed for many years at the *London Hospital*, Whitechapel, an association of extreme utility, most highly creditable to the projectors, styled the *Samaritan Society*. Its object is the relief of circumstances of distress in persons presenting themselves at the hospital, which cannot be provided by the Institution itself. For instance; domestics who have been obliged, by sickness or accident, to quit their places, when discharged from the hospital, are frequently without the means of support until other places can be procured. Many patients are so destitute as to require partial clothing before they can leave the Institution. Many are natives of distant parts, and, without assistance, would be unable to reach their parishes. Innumerable inducements exist for the formation of a society of the like nature, in connection with the *North-London Hospital*. Time, however, has not been afforded to organize a plan, though a subscription for the purpose was set on foot soon after the opening of the hospital, the disbursement of which has been judiciously attended to by the Matron (Mrs. Hunt), to whom, until the Society is formed, it is respectfully requested that contributions (most acceptable, however small the amount) may be forwarded." We add, our most cordial recommendation of the object, to the humane.

ROYAL INSTITUTION.

Friday, January 22, 1836.

SILICIFICATION OF PLANTS.

THIS was the first meeting, for this season, of the members in conversation. We observed amongst the visitors many of the most distinguished *literati* and *illuminati* of the day. Dr., or rather Mr. Faraday (for we understand scruples of conscience interfere with the full acceptance of the Oxford

diploma by this gentleman), selected for the subject of this evening's lecture, the changes effected in fossil plants, which process he, in common with Dr. McCulloch, has called the *silicification* of plants.

Silex or *silica*, or, in common parlance, *flint*, as the professor said, is one of the most common of substances; it abounds in sand, in clay, in crystal, and in various earths; it also circulates in, and is secreted by, living plants, as, for example, the grasses. The properties of this substance are very suitable to so general a constituent of nature; it is insipid, inodorous, and resists the action of ordinary reagents. It also resists, to a greater degree than any other compound substance, the influence of heat. Mr. Faraday has never succeeded in reducing it to a gaseous form, and is disposed to think the experiment quoted by Dr. McCulloch as fallacious. As Dr. McCulloch succeeded in only one instance in sublimating the silica, probably the presence of calcareous matters might account for the deposition on the surface of the receiver. Silica may be reduced to a very fine powder, and the lecturer exhibited a quantity in a state of extremely minute division. It is, as already intimated, a compound body, consisting of an element called *silicon*, and oxygen. This silicon is a brown metalline body, not acted upon by water.—a circumstance in which it differs from other bases of earths. Silica, with the exception of *calc*, is the most general constituent of nature; it constitutes almost the entire of flint, agate, calcedony, amethyst, and each crystal. Flint is discovered in great abundance in the fissures of the chalky strata, being distributed in laminae, which lie occasionally parallel to those of the chalk, and occasionally dissect them at various angles, cutting up the chalk into rude squares, rhomboids, and other mathematical forms. Nodules of silica, in the form of agate, are found in the middle of other stones, where it exhibits a beautifully crystalline disposition. In calcedony, a form of *silex* familiar to many, the soft character of the outline shows the substance to have been once plastic. One character is peculiar to silica, that of forming glass when in union with a common alkali; when thus united, it is soluble in water, and it may be precipitated in the form of gelatine, by the addition of an acid. This gelatine contracts in dimension as it solidifies. The proper subject of the lecture was the silicification of plants, or that delicate and unexplained process by which the original matter is removed, and supplanted by siliceous deposit. This species of *substitution* has nothing similar to it amongst any of the phenomena of nature; it is so particularly delicate, that the botanic character of the plant is perfectly preserved, all the vessels, fibres, &c., being in form and colour an exact transcript of the original structure. The most skilful manipulation

could not macerate, or, in any other way illustrate, the organic vegetable derangement, without injuring the parts to an infinitely greater degree. Several examples are extant of fossilized woods, both of the endogenous and exogenous classes. These are preserved in all stages of growth, from the germ to the mature tree, and in all degrees of decay, even to the most fragile touchwood. What is remarkable, is the conservation, not only of the actual solid, but of the *area* of the vessels, which are filled up with white, or semi-transparent agate. In the decayed woods, the deficient parts are also represented by the same kind of agate. Dr. Turner has formed an hypothesis for the solution of this interesting process. He supposes these fossils to be formed in such situations as are exposed to the action of silica, dissolved in the alkalized streams of water, which are sometimes met with. Many considerations are opposed to this supposition. These fossils are always produced deep under the surface of the earth, away from the influence of air and water; the theory of infiltration will not account for the fossilization of such very tender and perishable parts as the seminal leaves of a plant. The infiltration of these plants would, as far as our present knowledge of physics intimates, require many years for its completion,—a circumstance inconsistent with the accurate preservation of evanescent structures. Mr. Faraday is of opinion, that we have no knowledge whatsoever of the nature of this process. He thinks our only mode of inquiry must be confined to an examination of silica, in order to an exposure of some of its occult properties. A careful search also may develop some specimen of fossilization, where nature has been impeded in her proceedings, and her nostrum betrayed, the change being exhibited as it were *in transitu*. The instances of recent fossilization, which have as yet been produced from various places, are mere incrustations of calcareous or even of siliceous matter, where there has been no preservation of organic forms, none of that beautiful and incomprehensible *substitution*, which, while it excites our admiration, baffles our curiosity.

Several splendid specimens of fossilized wood were kindly furnished for the occasion by Mr. Brown, the celebrated naturalist, and Sir Francis Chantrey, the distinguished sculptor.

LONDON INFIRMARY FOR DISEASES OF THE SKIN.

(From a Correspondent.)—A public meeting of the friends of the above-named institution, in aid of its funds, was held on Monday evening last at the Committee Room, 51, Great Ormond Street, J. C. Carpus Esq., F.R.S., in the chair. The venerable

chairman opened the business of the meeting with an able address, explaining the objects of the institution, and earnestly inviting its friends to come forward promptly in its aid, almost the whole of the expenditure, since its revival, having been hitherto defrayed by the medical officers. He stated his expectations, that if well supported by the public, it might, ere long, equal in public utility the great hospital of *St. Louis* in Paris,—and mentioned the researches which had been lately made by Dr. Litchfield, and some of his colleagues, on the itch insect, the existence of which had been fully demonstrated by him.

The secretary, Mr. BRENT, then read a report on the state of the charity, which had been the means of relieving a great number of patients, in many of whose cases a complete cure had been effected. He stated that he had great hopes of public support in behalf of the infirmary, and that the attention he had received in his canvass in the immediate neighbourhood, and the interest its re-establishment had excited there, had greatly exceeded his expectations. He read letters which had been addressed to him from the Duchess of Kent and the King of the Belgians, who have been graciously pleased to extend to it their patronage, and also one from Sir John Conroy, announcing his assent to become a vice-president, agreeably to the request of the Committee.

A number of gentlemen added their names to the list of subscribers, and it was determined that the present meeting should be only preparatory to one on a much larger scale, to be held shortly at the *Thatched-House Tavern*, or some other public room, at which the president, or one of the vice-presidents, should be invited to take the chair.

NORTH-LONDON HOSPITAL.

ERYSIPELAS OF THE HEAD.—REMARKABLE EFFECTS OF THE EXTRACT OF BELLADONNA.

MARY PECKS, aged 32, was admitted under the care of Mr. LISTON, on the 21st of January, labouring under severe erysipelas of the head and face. The patient was admitted into the hospital on the 30th of October, last year, for a similar attack, affecting the same parts; she was then very successfully treated with tartarized antimony, incisions, and fomentations. The attack was probably not more severe than the present one, in the first instance, but it had been allowed to proceed for four days without the administration of any remedy. The convalescence was rendered rather tedious, from collections of matter forming in various parts of the

scalp. She was, however, discharged, quite well, on the 22nd of Jan. 1835, and remained in good health until the evening of the 20th of Jan. 1836, when having left the house very thinly clad, she suffered considerably from the cold. During the same night she was seized with rigors, which were succeeded by heat, pain, and tingling of the head and face: on the following morning her face was so much swollen that she could not see. On being brought to the hospital on the afternoon of the 21st, her whole face and scalp were enormously puffed, and very tense; her eyes were completely closed, the pulse 110, the tongue covered with a thick yellow fur, bowels open from medicine. She was wild and restless, and her hearing appeared to be morbidly sensible; she answered questions put to her, in a vague and hurried manner. Fomentations were applied, and a quarter of a grain of tartarized antimony in some saline mixture was given every hour.

22nd. Has passed a restless night, complains of the pain being more smarting; pulse 160; tongue still furred but moist. She was now ordered a mixture containing one grain of the extract of belladonna in sixteen ounces of water, of which two tablespoonfuls were given every three hours. The eyelids to be freely punctured, and to continue the fomentations. A ring of the nitrate of silver was drawn around the neck.

23. Very much improved, has passed a good night; the swelling and redness are greatly diminished, the surface appearing wrinkled; pulse 96; tongue still furred; bowels open. The patient says she is very much better. A small quantity of pus, which had collected over the right parietal bone, was evacuated.

24. Rapidly improving; swelling and redness nearly gone; pulse 96; bowels not open; to have a dose of house-medicine. Convalescent; discontinue the mixture.

In going round Mr. LISTON remarked that this was one of the most satisfactory and successful cures of erysipelas he had ever seen, the disease entirely, though not suddenly, disappearing in the course of a very few days. He was inclined to attribute this to the treatment, both local and general, which had been adopted, but more particularly to the administration of belladonna. This the students might be aware, was given on the homœopathic principle, the doses only being somewhat increased. They had all probably seen the good effects of the aconite, and some of the other remedies employed by the advocates of homœopathy.

DISLOCATION OF THE HUMERUS ON THE DORSUM SCAPULÆ.

This rather unusual accident lately occurred at this hospital, to a woman, who stated that she had fallen on the point of

the right shoulder. The humerus was dislocated on to the dorsum of the scapula. The following symptoms presented themselves:—A hollow underneath the acromion, and a large firm tumour, resembling a small orange, on the dorsum scapulae, beneath the spine of the bone, and which moved on rotating the humerus. The arm fell nearly perpendicularly, the elbow pretty close to the side. Mr. MORTON, the house-surgeon reduced the dislocation, by an assistant fixing the scapula and grasping it with both hands. Extension was then made by Mr. M., from the hand with the arm held out at right angles with the body. The head of the bone returned with a very audible snap. The arm was then slung, and fomentations were applied to the joint.

I should feel very greatly obliged by your noticing the above defect. I am, Sir, yours obediently,

ROBERT DRUITT.

King's College, Feb. 3rd.

. The letter we believe was printed as written.

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications to Mr. WAKLEY may be addressed to him at his residence, 35, BEDFORD SQUARE.

To the Editor.—SIR,—Having been absent for some weeks in the country, my attention has only been lately directed to a paragraph in your journal, referring to the note of mine which you did me the favour to insert. You may remember that the note in question related to the numbers of the pupils in attendance at the new anatomical school in Kinnerton-street. I stated that there were 42 *bona-fide* pupils, independently of others to whom the lecturers had given tickets. It appears that you have received several letters impugning this statement, and implying that the number of *bona-fide* pupils is not so great as I represented. Now, Sir, I repeat, upon my word of honour, that what I stated is strictly correct, and that the number of gentlemen who have actually paid their money for their tickets does amount to forty-two. Besides these gentlemen, twenty-three others are in attendance, making in all sixty-five. As my accuracy has been called in question, you will, I am sure, permit me thus publicly to repeat my assertions, and again to refer to the books which lie on the museum table, as evidence of the correctness of my statements. I am, Sir, your obedient servant,

JAMES EVETT.

Kinnerton-street, Jan. 27, 1836.

ERRATUM.—To the Editor.—SIR,—I have observed an error of the press in my letter which appeared in the last number of your journal. The last few lines of the second sentence ought to have been as follows:—Because they have not like himself been *seduced into attendance there*, and have not gratified by an “*exorbitant fee*” the fraudulent extortionacy of its “*governors or functionaries*.” The words between inverted commas are, as nearly as I can now recollect, those used in the letter to which mine was written as an answer.

In a notice of “Andral's Clinique” a short time since, we stated that the price of Dr. Spillan's translation, published by Benshaw, scarcely exceeded that of the original work. The following correction of this observation should have been made in the ensuing number: The French edition is published at forty francs, and is sold in London at forty shillings; the Brussels edition is sold in London at thirty shillings; Dr. Spillan's translation, when complete, will sell at twenty-five shillings, being five shillings less than the foreign edition.

A Non-Professional.—The prevalence of such an “opinion” is news to us. As a matter of form, perhaps, the custom is abating. Its uses are numerous.

One of the Meeting.—The proposal would be right enough, but the parties would, unfortunately, have to struggle against the law by its adoption.

A Medical Apprentice.—Conformity with the custom ought not to be rendered compulsory, and then, whenever voluntary compliance is yielded, the terms of a proper agreement would unquestionably be obeyed. Doubtless a change will be made in the law.

We have found it impossible to insert this week the letter of Mr. Prater, and in order to give the whole of the St. George's Hospital proceedings at once, we must again defer our report from the board-room of that institution.

We will insert the letters of A Suffolk Practitioner, Mr. Beddingfield, and K.

The letter of Mr. Carmichael appeared at page 714 of our number for January 30. The very earliest opportunity was taken for giving it insertion.

We are requested to point attention to an advertisement on the cover of this week's LANCET announcing the first meeting of the

Medical Association projected at the last meeting of the Crown and Anchor Tavern. The fullest opportunity, we are assured, will be afforded on this occasion for making proposals relative to the rules and regulations of the association, to the great body of students who are expected to attend.

Mr. JAMES BAKER (whose letter was not received until a very late hour) wishes us to draw attention to an advertisement on the cover of THE LANCET, containing some particulars of a petition which he has prepared to be presented to the House of Commons, praying for the enactment of a law which shall award a just proportion of remuneration to medical men for devoting their time and services in the elucidation of facts at coroners' inquests.

Mr. SOPWITH, in a reply to the letter of Mr. Way, "most distinctly states that Mr. Way did not, at their first interview, *disclaim* any authority as a member of the Committee for the course he was pursuing, but that on Mr. Sopwith's refusal to comply with his request being clearly given, Mr. Way *did use the threat* stated in Mr. Sopwith's last letter, and," Mr. Sopwith adds, "in a tone of voice which was evidently intended to convey more meaning than the words ex-

pressed. To show Mr. Way," Mr. Sopwith proceeds, "that neither the prospect of exclusion from all future medical meetings, nor the denial of professional aid when needed, would induce me to forget the courtesy due from one gentleman to another, I did bow and thank Mr. Way for the trouble he had taken in calling upon me, but that gentleman was too far led away by his feelings of chagrin at my cool refusal, to distinguish between the motive which induced me actually to thank him, and that expression of thanks which is meant to convey a sense of obligation for some real favour conferred. That Mr. Way was much surprised at my referring to his conduct before the whole of his professional brethren, I can readily believe, for, forgetting he had overstepped the line of prudence in his capacity of committee-man, and scarcely expecting that a practitioner of only two months standing in the place, would presume to request an explanation of his conduct before the association, it was very natural for him to be both surprised and annoyed at being called upon unexpectedly to exonerate the body he in part represented, from all participation in his proceedings, and to acknowledge that he had acted upon his own responsibility alone. With such an explanation the members of the Association were of course satisfied, having nothing to do with Mr. Way's private motives or actions as unconnected with them."

Mr. Sopwith's letter is dated Jan. 20th, but we have not before been able to secure room for any portion of it, a circumstance which has caused us regret.

The insertion of several reports and communications is unavoidably postponed for a week.

A Constant Reader of THE LANCET is informed, that he is entitled by law to make the claim in question, but there is no law which enables him to support it.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XI.

HYPERTROPHY OF THE NERVOUS CENTRES.

GENTLEMEN,—We have now to enter upon the study of a class of nervous diseases different from those which have hitherto occupied our attention. We have to lay before you the history of hypertrophy of the cerebro-spinal axis, of its atrophy, of ramollissement, and, finally, of induration; after having completed the history of these four lesions, we shall occupy ourselves with lesions of secretion.

Let us commence with hypertrophy of the nervous centres. This lesion may be seated in any one point of the cerebro-spinal axis, in the cerebrum, in the cerebellum, the medulla oblongata, or any portion of the spinal chord; however, we shall take for our type hypertrophy of the cerebral hemispheres, and describe the anatomical characters of that lesion, observed in this part of the nervous system, as applicable to the whole.

Hypertrophy of the hemispheres of the cerebrum is distinguished by the following

Anatomical Characters.

The nervous substance is firm and dense, and opposes unusual resistance to traction; its colour is, in general, more pale than common, and the hypertrophied tissue does not contain any considerable quantity of blood. DANCÉ was one of the first who wrote upon this subject: you will find an excellent

memoir of his on the history of hypertrophy of the brain in the *Repertoire d'Anatomie*, published by M. BRESCHET, vol. 5, where the pathological anatomy of this disease is described with great minuteness and fidelity. The nervous tissue, as we have just said, seems to contain less blood than natural, and when you divide the cerebral substance into slices, you observe but few of those small reddish points which are ordinarily disseminated through the nervous mass when in a normal condition. Thus hypertrophy may exist without hyperæmia. It is not an excess of blood which forces the nervous molecules to occupy a greater space than is natural, but the increased bulk depends on an augmentation in the number of those molecules themselves.

When you divide the substance of the brain, the cut gives a dry even surface, which does not present that humid aspect natural to the brain. The same appearance is observed externally; the superficies of the brain is in like manner dry, and it would seem that the normal exudation of fluid which takes place from the arachnoid and pia mater, has been either diminished or suspended. The convolutions are flattened, and approximate together; there does not seem to exist any space between: the latter circumstance is readily explained by the pressure exercised in consequence of hypertrophy. The membranes are closely applied to the cerebral surface, and seem as if they were too tight for the organ which they envelop. The ventricles are, as it were, effaced, and we observe no tendency whatever to effusion within their cavities. The nervous mass, developed beyond measure, seems to occupy the place left, by all the compressible parts yielding to make room for it.

We may now follow the lesion which we have just briefly described, through the different portions of the cerebro-spinal axis. Examples of hypertrophy have been observed in the cerebral hemispheres, in the cerebellum, in the spinal marrow. We propose to study the lesion in each of these portions of the nervous system, apart; and 1st for

Hypertrophy of the Cerebral Hemispheres.

The lesion may occupy the whole mass of the hemispheres, or it may be partial, occupying

but a small portion of the nervous tissue. We shall put on one side the latter species, to consider it at the end of our lecture, and occupy ourselves exclusively at present with general hypertrophy of the hemispheres of the brain. When the augmentation of volume thus comprises the totality of the cerebral mass, two cases may present themselves, which it is important to distinguish, depending on the relative proportions of the hypertrophied nervous substance, and the osseous case in which it is enclosed and supported.

In the first of these two cases, at the same time that the brain, in becoming hypertrophied, tends to occupy a greater space, the osseous parietes surrounding it are equally developed, and we may form an exact estimation of the size of the brain from the magnitude of the cranium. In the second case the brain is hypertrophied, as in the former, but the osseous cavity does not show any tendency to develop itself; the dimensions of the skull are normal, while the relative size of the brain is greatly increased. It is necessary to distinguish carefully these two cases; for, in the first, we may have no accidents which betray the abnormal augmentation of volume in the brain; the skull being developed in the same proportion as the cerebral mass, we can have no compression, and the case may go on for a great length of time, or even to the end, without any of the functions being troubled in a notable manner.

In the second case, which observation has shown to be much more frequent than the first, the osseous parietes do not follow the exaggerated volume of the nervous tissue; hence the brain is necessarily subjected to an habitual compression, and various accidents may ensue; instead of the symptoms of compression, we may have those of irritation or congestion, and their numerous accompanying phenomena, all depending on the greater or less degree of disproportion between the containing and contained parts, between the cranium and brain. So much for the pathological anatomy of hypertrophy of the cerebral hemispheres. You see how it gives a key to many of the symptoms of this affection, and you will not fail to observe the utility of the arrangement we are accustomed to follow in this and our other courses, in which a description of the morbid appearances preceding the history of the disease, and its symptoms, leads you naturally to anticipate a great number of points connected with it, or at least prepares you to understand more perfectly the history of its march, phenomena, and terminations.

Can we ascend to a knowledge of

The Causes which favour Hypertrophy of the Cerebral Hemispheres?

We are compelled to acknowledge that

the causes of the lesion now under consideration are completely, absolutely, unknown. Congestion of the brain has been mentioned as one of the exciting causes of hypertrophy; this may be the case, but we are not in a condition to prove it; in theory, we might admit that the frequent repetition of hyperemia is calculated to produce an hypertrophy of the cerebral substance, but, on the one hand, remember how paleness is one of the anatomical characters of this alteration; while, on the other hand, we have not observed any trace of hypertrophy in a great number of individuals who for a long time had been subject to cerebral congestion. It has also been affirmed, that long-continued and energetic action of the brain, particularly exercise of the intellectual faculties, may give rise to the development of hypertrophy of the cerebral hemispheres. Some writers assert, that on examining the heads of intellectual persons, of individuals remarkable for some great intellectual faculty which they possess in a high degree, the organ of the brain corresponding to this faculty or power exhibits an excess of development, a true species of hypertrophy. This may be the case; it is even probable; but truth compels us to say that it has not yet been demonstrated. We have the more difficulty in admitting the rapid development of any cerebral organ in connection with its activity, as physiology teaches us that nutrition goes on much more slowly in the nervous pulp than in the osseous or muscular tissues, and that we cannot in any way establish an analogy between what takes place in this latter system, as a consequence of long-continued exercise, and the development of the brain, or any portion of the brain, in persons accustomed to laborious mental occupations.

Hypertrophy of the nervous centres is not a disease common to all

Periods of Life.

Thus we are not as yet acquainted with a single case of this lesion observed in an individual who has passed the age of 35. All the cases recorded in the annals of the science, refer to persons below the age just mentioned: it has been seen at from 30 to 20 years, and even at a much earlier period of life; in one case recorded, the patient was a child five years of age. Let us now study

The Symptoms

which accompany hypertrophy of the cerebral hemispheres. In the first place we have to remark that this lesion is sometimes unaccompanied by any symptom whatever; this happens when the osseous parietes are developed at the same time, and equally, with the brain. Here compression does not exist; we have no irritation, no cause of congestion, and the abnormal development of the brain does not produce any notable trouble in the economy.

A remarkable case of this kind has been communicated to us by M. SCOUTETTEN; you will find it in the *Archives Générales de Médecine*, t. 7, p. 31. It was that of a child five years old, whose head had acquired a degree of magnitude equal to that of an adult. This augmentation of the skull had taken place gradually: however, the intellectual faculties were not at all troubled; the child did not differ from others of the same age: there was no modification of sensibility or motility worth mentioning. This child died from acute inflammation of the bowels. After death the head was examined; the substance of the brain was found considerably exaggerated, especially in the nervous mass situated above the ventricles, and the parietes of the skull, a little thinner than usual, were developed to a size corresponding with the increased bulk of the brain. Here then is a case where the lesion of which we treat was not announced by any symptom.

Lesions of Intelligence from Hypertrophy.

Whenever hypertrophy of the nervous centres is not accompanied by a proportionate development of the cranium, we have a series of accidents produced that may reasonably be referred to irritation or compression of the nervous substance. These accidents may be distinguished into lesions of intelligence, of sensation, and of motion. When the hypertrophy is established in a gradual and slow manner, the intellectual faculties become dull and obtuse. In all the cases which are cited by authors, and in those I have had occasion to observe myself, this diminution of the intelligence existed. Several patients were reduced to a perfect state of idiocy: others had not lost their intelligence, but preserved it in a weakened form, and fell from time to time into a transitory state of imbecility. In other cases we find a perversion of the intelligence: the patient becomes delirious, or sinks into alienation of the mind, and mania. Thus you see how variously the intellectual faculties may be modified or perverted in cases of hypertrophy of the brain, when the skull does not keep pace with the development of the nervous substance. The troubles of intelligence just enumerated may be prolonged with different degrees of intensity, or they may terminate, more rapidly, in delirium, followed by coma and the death of the individual. This is what we have to remark in connection with the intelligence, and the phenomena which it may exhibit. Now for sensibility; what accidents do we observe in connection with the sensibility?

Is Sensibility Modified in Cases of Cerebral Hypertrophy?

Yes. Observation shows that in most cases the modification of sensibility manifests itself by an habitual headache: this, becom-

ing exasperated at certain intervals, and attacking the patient most violently under the form of intermittent cephalalgia, is sometimes a symptom of cerebral hypertrophy. In the first case mentioned by DANCER, it was the predominant symptom: we can easily understand how this modification of the sensibility shows itself in headache. The brain is more or less compressed in an osseous case too small to contain it, and must therefore necessarily suffer in proportion to the degree of violence it has to undergo. Several patients experience vertigo, giddiness, &c., as if affected with simple congestion of the brain, and the sensibility in general is modified. In some cases the loss of sensibility is gradual and slow; but in others, after having remained a certain time intact, it is suddenly abolished: this latter circumstance is remarkable, and we would briefly direct your attention to it. Here is a sudden loss of sensibility produced by a chronic alteration of the brain. How do we explain this? Why should the sensation remain perfect up to a certain moment, and then suddenly disappear? It is not easy to find a reason for this phenomenon, although we have frequently occasion to remark the same thing in other organs, where a chronic disease may exist for a considerable time without producing some one of the principal symptoms which it ought from its nature to develop. Yet at a period when we least expect it, without any change in the march of the disease, or in the condition of the patient, this symptom, so long in abeyance, suddenly makes its appearance.

Lesions of Motility.

The disorders observed in connection with the faculty of motion are various, and may be specially comprised under the following heads. In many cases we find convulsions, either appearing with little intensity, or coming on at certain intervals. This modification of motility is chiefly seen in children and infants, for it is a general principle, abundantly confirmed by experience, that whenever the nervous centres are troubled in persons of a tender age, this lesion manifests itself in the form of convulsions. In some cases we observe nothing but simple convulsive movements, repeated from time to time: in others the convulsions assume a more grave form, and present themselves with all the characters of epilepsy, terminating in the patient's death: it is a fact now incontestable, that epilepsy may depend on hypertrophy of the brain. We have had occasion to examine a few cases of this kind, and the only lesion which existed,—but it was one that was most evident, impossible to be overlooked,—was an hypertrophy of the hemispheres of the brain. Here then you have examples of excitation of the locomotive powers in connection with cerebral hypertrophy. In other cases we observe

phenomena of quite an opposite nature: certain patients are affected with a gradual diminution of motility. This weakness of the limbs becomes more and more decided, and at length terminates in complete and general paralysis. It has also been observed that the loss of movement suddenly comes on, in a few cases, after a violent access of convulsions. In all we have now said, you see confirmed a principle that we laid down in the lecture introductory to the present course. You here see that lesions identical in nature,—for we have treated all along of hypertrophy—identical in its seat,—for we have as yet spoken of the cerebral hemispheres only,—may produce not only various, but even opposite symptoms. You see how difficult it is to arrive at the real cause of disease when the phenomena upon which we have to found our judgment are so diversified and contradictory. Finally, you will observe, that these sources of difficulty, common in a certain respect to all the systems, present themselves more frequently and with more obstinacy, if we may use the term, in the study of diseases of the nervous system.

Respiration, Digestion, and Circulation.

The functions of organic life also present some modifications in cases of hypertrophy of the cerebral hemispheres. but in general we may lay it down as a principle that they are not affected. The respiratory functions are not compromised unless the disease has produced a profound impression on the motility; it then becomes embarrassed and difficult, merely because the mechanical agents which dilate and contract the chest, have lost their power of acting. The digestion is not affected during the course of the disease. As to the circulation, it very rarely presents any modifications worthy of notice; in most cases the pulse beats with its ordinary degree of frequency; in one case only do we remember to have observed a disturbance of this function. The pulse is here more accelerated than natural, but as the case is solitary, it must be regarded as exceptional, and we conclude for the circulation as we have done for the respiration, that it is not implicated amongst the disorders of hypertrophy of the brain. Whenever any excess of frequency is observed, it probably depends upon some complication of the disease, not on the cerebral lesion itself. In all the cases we have seen, except the one already mentioned, there was complete apyrexia; indeed the pulse has on the contrary a tendency sometimes to fall below the natural standard. In one case the number of pulsations was seen so low as forty-five in the minute; but this also must be considered as exceptional, or perhaps it was the natural standard of the pulse in the individual who formed the subject of observation.

The different symptoms which depend on hypertrophy of the nervous centres, group themselves together in such a manner as to give a certain march to the disease, and distinguish it into two distinct forms or periods. In the first, it presents itself with all the characteristics of a chronic affection. Then follows the second period. The disease is now acute, it marches rapidly, and the patient succumbs. In almost all the cases which we have observed ourselves, or found recorded in authors, this succession of periods exists. The malady commences in a chronic form, and after having pursued its course for a certain length of time, it terminates with symptoms of an acute nature. During

The Chronic Period

we see appear successively all the phenomena that have been already noticed, except delirium; such as various troubles of the intelligence, headache, convulsive motions, and, finally, epilepsy. These different symptoms may manifest themselves simultaneously in the same patient, or exist singly, in an isolated manner. When this chronic stage has passed through a variable period of time, the acute stage commences, and then we find various symptoms, different forms of disease. In some cases, the predominant symptom is a violent access of convulsions, in the midst of which the patient dies.

The Acute Period.

In other cases, acute hypertrophy of the cerebral hemispheres gives rise to a set of phenomena that are closely allied to cerebral congestion. These may simulate various diseases of the nervous system, and, in particular, cause disturbances very characteristic of acute hydrocephalus. I had occasion to observe at the *Maison Royale de Santé* a case which fully establishes the truth of this latter observation; the patient was brought into the establishment with delirium, and other signs of inflammation within the cavity of the cranium; he fell rapidly into coma, and was agitated by some convulsive motions; the breathing became embarrassed and stertorous, and the patient died. Before death, we had regarded the case as one of acute hydrocephalus, but on the autopsy what did we find? No trace of meningitis; no effusion whatever of serous fluid into the ventricles. On the contrary, the brain presented all the characters which we have described as constituting hypertrophy of the nervous substance. This case was a very remarkable one. The symptoms had the strongest resemblance to those which ordinarily attend acute hydrocephalus, and might have deceived any physician.

Varieties of Cerebral Hypertrophy.

In a disease where the cases that have

been observed are rare, it is useful to draw your attention to particular observations. Thus, we cannot conclude this part of our subject, without noticing the case published by DANCE, in which the patient died as suddenly as if he had been struck by a violent attack of apoplexy, although the disease had not passed beyond its chronic period. The individual, who had laboured for some time under a violent headache, went to one of the warm-baths in the hospital; he remained about three quarters of an hour in the bath, and on coming out was seized with a fainting fit; this continued for a quarter of an hour, but consciousness never returned. At the expiration of that short period the patient was no more.

Treatment of Cerebral Hypertrophy.

We have now concluded a brief sketch of the history of hypertrophy of the cerebral hemispheres; what shall we say of its treatment? It is obvious that we possess no special means of combating the material cause of the disease, the abnormal development of the nervous pulp; our efforts must, therefore, be confined simply to palliate the different symptoms as they present themselves; and the means to be employed for this end are so simple, they follow so naturally from the description we have given of the accidents attending hypertrophy, that we think it superfluous to insist on them at present. We shall, therefore, pass at once to the study of

Partial Hypertrophy of the Brain.

The lesion which now occupies our attention, when confined, as it sometimes is, to a particular region of the brain, may occupy either the deep-seated or the superficial parts. In the deep-seated parts its occurrence is much more rare; however, we have seen examples of this species of hypertrophy. We can affirm with certainty that we have seen cases in which the augmentation of the nervous tissue was confined to the corpora striata; to the corpora ammonis, or the optic thalami; hence we are compelled to admit, on the evidence of our own senses, the existence of partial hypertrophy in the deep-seated portions of the cerebral hemispheres. Now for hypertrophy of the circumference of the brain.

Were I to attempt to lay before you a complete history of partial development of the cerebral organs, we should find ourselves at once involved in the grand question of the doctrine of Gall; for his theory rests entirely on the relation which exists between the development of certain moral or intellectual faculties, and the corresponding hypertrophy of certain portions of the brain which he regards as the special organs of these faculties or propensities; it is impossible for us to enter upon this interesting debate; it belongs rather to physiology than

to pathology. All we can say at present is, that as it touches certain parts of pathology, we shall take an opportunity of recurring to it when speaking of mental alienation.

Hypertrophy of the Cerebellum, and its Influence on the Genitals.

We have said that hypertrophy of the nervous pulp may exist in certain portions of the cerebro-spinal axis besides the cerebellum; examples have been seen in the cerebellum. When this part of the nervous centre is hypertrophied, the disease presents itself with the anatomical characters which have been assigned to hypertrophy of the cerebral hemispheres. It is unnecessary to repeat their description here; it may occur without any appearance of development in the cranium, or the hypertrophy may, in other cases, be attended by a corresponding augmentation in the diameters of the osseous cavity which encloses the cerebellum. Here, again, a highly interesting question presents itself. What influence does this exaggerated nutrition of the cerebellum exercise on the generative organs? Do we find the natural impulse of reproduction elevated with that development of the organ to which some physiologists attribute it? We cannot now enter into an examination of this question, which would be foreign to our purpose; however, we cannot avoid mentioning one or two particulars that seem to throw light on the connection existing between the cerebellum as an organ, and the impulse to reproduction as a function. In the year 1828, M. FELIX VOISIN paid a visit to the galleys of Toulon, with the express object of determining whether certain predominant faculties are accompanied by certain external signs, the indications of development in certain portions of the brain; he chose, as a test of this doctrine, the reproductive impulse; he examined and measured the heads of 372 individuals confined in the galleys, proposing to select those who had been confined for the crime of rape; the number of these individuals amounted to twenty-two. M. VOISIN, without any other indication than that which he drew from an examination of the occipital region, pointed out twenty-two amongst the 372 as the persons condemned for the crime just mentioned. On comparing his list with the returns of the prison, he found that of the twenty-two so selected by him, thirteen had really been confined for rape, or attempt upon female chastity; a great many of the remaining individuals were marked as convicts of bad morals, men whose propensities in a certain way required the strictest watch over them.*

Here is a curious coincidence of facts,

* These curious particulars may be found in the Journal of the Phrenological Society of Paris, No. 1, 1835.—ED. L.

and, remark, that if M. VOISIN did not discover all the individuals confined for the crime of rape, this is no valid objection against the proposition which he wished to establish, because many men are led to the commission of this crime, not from the imperious dictates of nature, not to satisfy an actual animal want or desire, but under the influence of imagination, revenge, and various other motives of a similar kind.

In some cases of hypertrophy of the cerebellum, this organ seems to encroach on the nutritious materials of its osseous parietes, which it takes to itself to appropriate to its development. Here a portion of the skull is absent, and the nervous substance forms a hernia externally, projecting more or less beyond the walls of the cranium. M. LALLEMAND cites an example of hernia of the cerebellum, although he does not say specifically that the nervous substance was hypertrophied. Another case, published by Dr. BENNET, may be found in the *Gazette Medicale* for 1834, No. 42, p. 667. This is a very curious example, and deserves to be cited at some length:—The subject of this observation was born in the year 1815, and at the time of birth presented no abnormal appearance; however, about four weeks after birth, a small tumour was noticed near the right mastoid process, projecting about half an inch beyond the surface of the bone. The tumour remained nearly in the same condition for two years, when Mr. BENNET, then a student in medicine, attempted to remove it; but the first incision was scarcely practised, when a medullary substance escaped, and the child sank into a state of insensibility. The wound was closed at once, and the infant recovered after a lapse of six or eight weeks; a second tumour now appeared on the opposite side, and both commenced to grow by degrees, until at length they were limited by one large base; at the age of six years the united tumour was as large as a hen's egg; it was now evident that a portion of the cerebellum projected through an opening in the cranial parietes. Whenever a slight pressure was exercised on the projecting mass, the child immediately lost consciousness, and on recovering, complained as if she had been struck roughly on the head. Up to this period she enjoyed perfect health; the intellectual and other faculties were developed in a regular manner. There was no modification whatever of the sensibility or of motility; however, another phenomenon was observed; at the age of eleven, the first symptoms of venereal passion showed themselves. The girl was seized with a furious desire for the male sex, and all the efforts of her mother were unable to prevent her from giving herself up to the most unrestrained libertinage. When confined to the house, the imperious desire by which she was tormented, declared itself in abandoned

movements and excessive masturbation. This state of passion continued unabated up to the age of seventeen, when she died suddenly, in consequence of having carried a heavy weight on the head. The examination of the tumour after death showed that a portion of the cerebellum, enormously developed, had projected through a deficiency in the osseous case of the cranium. Here, then, we have a manifest proof of the influence which hypertrophy of the cerebellum may exercise on the genital organs.

These are the principal facts that we know in connection with the subject now before us; but a great deal yet remains to be done before we can clear up the mysterious question of the relation between our faculties and certain portions of the brain and their development. There is, then, a splendid field open for observation and experiment; you might collect materials for a curious history, if you were to take all the cerebella you meet with, weigh and measure them accurately, and thus endeavour to ascertain what relation may exist between different conditions of this organ, and the feelings, habits, or propensities of the individuals from whom they were taken.

Hypertrophy of the Spinal Marrow

is the next subject for our examination: it may be either general or partial; the latter form has not been frequently observed. In one case that we saw, the lesion was confined to the cervical portion of the chord, which had acquired so considerable a degree of bulk as to fill completely the cavity of the vertebral canal. M. OLIVIER affirms, that when the spinal marrow is compressed at any one point, it acquires an increased volume immediately above the seat of compression. This is a curious fact. Does the medullary substance in these cases really take on an increased nutrition, and present the phenomena of an artery above the point of ligature?

Hypertrophy of the spinal marrow may be general, and then we observe two sorts or species: in the first, the chord has been found more voluminous in children who are born with various malformations of the body, and deficiency in the brain; there is a want of balance in the development of the cerebro-spinal axis, and the chord seems to have assumed to itself the deficiency of nutrition in the brain. A case of the first description has been published by M. LAZENNET, in the *Archives Générales de Médecine*, t. 5. The disease is congenital in these cases, and, as we have remarked, the hypertrophy of the chord is a supplement to the atrophy of the brain. In the second species we do not find any malformation of the brain, but the spinal chord, enlarged throughout its whole extent, as LAZENNET has observed, and firm in substance, fills the vertebral canal, and is exactly applied against its osseous parietes;

*The Symptoms of Hypertrophy of the
Spinal Marrow*

are not, in general, marked with any degree of clearness; on the side of the intellectual faculties nothing has been observed; in one case, where the augmentation of volume was confined to the cervical region, the patient, an infant, was subject to epileptic fits; however, we cannot say if this lesion were the cause of the disease or not, although the former is probably the fact. The absence of any striking symptoms depends perhaps on the circumstance that the chord, in this respect unlike the brain, has sufficient room to increase in its osseous case, without suffering compression, and does not give rise to any trouble of the great functions, unless congestion adds its influence to the operation of the original disease.

DISEASE OF THE URINARY ORGANS.

Delivered in the Session of 1836,

BY MR. LISTON.

LECTURE II.

Abscess with Stricture.—State of the Bladder.

GENTLEMEN,—The last time I had the pleasure of meeting you here, I endeavoured to explain to you, and to make you understand, the symptoms of stricture of the urethra, and some of the consequences arising from that disease, and I illustrated these remarks by reference to cases under treatment; I detailed to you the pathological changes which occur, the alterations that take place in the urethra itself, the manner in which the contraction is formed, the state of the passage, both anteriorly to the stricture and behind it. I explained how abscess formed behind the stricture, coming on sometimes very slowly, and ultimately bursting, with very great relief to the patient, a considerable part of the water, after a few days, being discharged through the opening, either in the perineum or in the scrotum,—some-
where thereabouts. Occasionally the abscess bursts into the rectum, giving rise to very unpleasant symptoms, and complicating the case considerably. This occurrence in general follows after severe injury of the perineum. I have seen it happen in two or three patients who had been bruised severely about the pelvic region from banks

of earth, for instance, falling upon them, though occasionally abscess forms far back in the canal in consequence of stricture, and bursts into the rectum, the greater part of the water being discharged through that channel. I stated to you also the changes that take place as regards the bladder. The balance in such case is lost, or, as the phrase is, there is a want of consent between the expelling and the retaining powers of that viscus, which becomes contracted, diminished very much in size, and its coats are remarkably thickened, in consequence of the resistance that is offered by the narrowing of the passage. I pointed out to you some specimens in which the muscular coat of the bladder was remarkably thickened, in which, in fact, the parietes resembled more those of the left side of the heart, than those of the bladder in its normal state. The mucous coat undergoes some alteration, and becomes more thickened and vascular, the mucous coat, occasionally, being found to protrude between the meshes of the muscular coat. Pouches are thus formed which often attain a very large size. I have in my collection some preparations, which, however, are rather bulky, and not convenient to remove, with several pouches so large as to be capable of containing a small orange. These pouches sometimes attain even a larger size, and seem to resemble almost another bladder. When the opening of the pouch is narrowed, the fluid is first evacuated (whether by the catheter or by the natural efforts) from the bladder itself, after which it comes away from the emptying of those sacs. Those appendages occasionally contain a considerable accumulation of viscid and acrid mucus, and there is no doubt that the abscesses connected with the bladder, which occasionally burst above the pubis, sometimes have their origin in this protrusion of the mucous coat through the muscular parietes.

But the mischief is not confined to the urethra and bladder only, for you find that in cases of stricture, sooner or later, the ureters and the kidneys suffer. You find, more especially when the patients have laboured under retention several times, that the ureters are immensely enlarged, and present a very wide caliber, almost resembling the small intestines; their parietes also are thickened; the pelvis of the kidney is enlarged, in consequence of the sort of valvular arrangement of the opening from the ureter into the bladder being obliterated. If a patient suffers frequently under retention, the ureters and the pelvis of the kidneys are dilated, the secreting substance of the kidney itself becomes disorganized, diminishes in bulk, is softened, and, in some cases, almost entirely disappears, presenting merely a sort of bag, formed by the enlargement of its pelvis,

with very little secreting substance at all.* In cases of retention of urine, you can easily satisfy yourselves, from the symptoms, that the kidneys are more or less affected. When retention has existed for a considerable time, the bladder becomes distended, to a certain extent, and then the secretions are suspended in a great measure; but after the bladder is relieved (the pressure probably being taken from the secreting substance of the kidney), the secretion is re-established with great vigour, and the bladder is filled, in the course of an hour or two, to as great an extent as in the first instance. When the kidneys and ureters, more especially the kidneys, are disorganized, from this or from any other cause, the patient may be relieved for a time, the symptoms may be palliated, but his ultimate recovery cannot be expected. He is then in a very precarious condition.

The Treatment of Stricture

demand your closest attention. It is a disease the management of which requires a great deal of skill and dexterity. I do not speak of the strictures which are usually met with—slight contractions of the passage, the mere spasmodic contraction, which is attendant upon thickening and irritability of the mucous lining of the canal, accom-

panied or not by a discharge, and, perhaps, with some uneasy symptoms about the parts. That is very easily got rid of by the occasional introduction of a proper instrument. There are before you a great variety of

Instruments used to Dilate and Examine the Urethral Passage.

All sorts of flexible and soft instruments are employed for the management of these diseases; but great objections may be offered to the majority of them. They are apt, unless very cautiously and properly used, to turn up, and bend, in the canal. They come out in a form like a hook, by being pressed against the stricture. They turn, as it were, upon themselves; or, again, if their points are entangled in the stricture, and efforts are made to press them on by turning and twisting them about, they come out like a cork-screw, well bathed in blood. You can never depend upon getting a bougie of this sort through a stricture of the urethra possessing any degree of tightness and elasticity. You are apt to do a great deal of harm with them. If you do insist on employing such tools for ascertaining the existence of a contraction, or for exploring its nature, seat, and extent, they must be used with very great caution indeed. It has been proposed to examine the passage with silver balls of different sizes mounted on wires, but these are scarcely ever employed now. The best instrument for the purpose, I believe, is a metallic bougie, such as I now show you, and you require to have them of different sizes, from below this size to considerably above it. Those, I think, are the best which are made of solid and firm metal, and plated over. You may have them of silver, if you will, but they answer the purpose perfectly well if their surface be smooth. You know exactly where the point of an instrument such as this is, resting. You can direct it in any way you think proper, by a slight movement of the hand. Pressure makes the point obey your will, and you can overcome every difficulty with the greatest facility. But in most cases, in trifling strictures, there is no obstacle. A great deal has been said about the lacunæ of the urethra entangling and obstructing the passage of the bougie. A very small flexible instrument may be so arrested. The contraction of the muscles may, occasionally, also, prevent, for a little time, the

* Mr. Liston exhibited at the commencement of the following lecture a very remarkable and beautiful specimen, illustrative of this pathological change in the bladder; it was obtained from the body of very young patient, under three years of age. This child, very delicate, was somehow seized with retention of urine, labouring under it unrelieved for several days. At last a catheter was used. It was found necessary to continue the introduction of the instrument twice a day for many weeks, the power of expelling the contents of the bladder having been lost. The patient was sent to the Hospital, under the supposition that he laboured under calculus vesicæ. No stone could be detected. All means were employed to palliate the symptoms; but the child, labouring under mesenteric disease, greatly emaciated, at length succumbed. The bladder is capacious; the surface rough and fasciculated. In the posterior fundus is an opening with rounded edges, of the size of a half-crown piece, leading to a cavity formed by a protrusion of the mucous coat, and capable of containing at least 5 or 6 ounces of fluid. The ureters are amazingly enlarged, and thickened in their coats, they resemble the small gut of a child; and the pelves of both kidneys, especially the right, are immensely expanded, the cortical and secreting part of the gland being spread out and attenuated.—*Rep. L.*

Introduction of the Instrument.

but by using an instrument of proper form and size, and by slightly diverting the attention of the patient, these difficulties are, in general, easily got over. I have frequently seen, where there has been slight obstruction from this latter cause, that by

turning the patient's attention in another direction, by diverting him by some trifling observation, or manoeuvre, the instrument has passed in immediately without any difficulty whatever. The muscles surrounding the bulb of the urethra, and the membranous portion, are those muscles which, by irregular and spasmodic action, may offer opposition, but by a little perseverance all these obstacles are to be got over. These muscles are sometimes thrown into powerful, and, in a measure, involuntary action, in consequence of the instrument coming in contact with the disordered and excitable portion of the lining membrane; the further progress of the bougie is thus opposed and prevented unless unjustifiable pressure is made and continued. Upon the pressure, which should be on all occasions gentle, being relaxed, the bougie is forthwith extruded; this is sometimes followed by the escape of a small quantity of blood, which shows the degree of tenderness of the mucous lining, and congestion of its vessels. The instrument is to be passed, if the patient be in the erect position, with the convex portion towards the abdomen. It is allowed to fall in by its own weight, by a *tour-de-main*, as it is called. You bring the convexity upwards, and then by depressing it very gently, you get over every obstacle. You may find, perhaps in the membranous portion a little resistance and grasping, a slight tightness of the passage from the action of the muscular apparatus supporting and surrounding it. That is very speedily overcome by gentle perseverance.

Object of the Introduction.

The introduction of an instrument thus gently, affords relief to the patient by diminishing the irritability of the passage, and, if there be any thickening, by promoting the absorption of that thickening. You are aware that the application of mechanical or chemical stimuli, from time to time, to any surface which is naturally irritable, or which has become so from disease, exhausts and diminishes the excitability or the irritability of the part. You introduce the instrument with that view, and allow all the effect of the introduction to pass over before you attempt to introduce it again. You perhaps introduce the instrument when the patient applies to you, allowing four or five or six days to elapse before you attempt it again, and upon the second occasion you will probably get the instrument through the contraction with greater ease; there is, perhaps, less irritability, you withdraw it again, and you are enabled to pass one of two or three sizes larger; and in this way you steal a march on the disease, and the patient in a few days is relieved from all his unpleasant symptoms, both as regards the urethra itself, the parts surrounding it, and those parts, also, which have sympathized with it.

Now, in cases of this kind,—slight and trifling strictures, as I have called them,—there is no use in any other mode of proceeding,—no necessity for having recourse to caustic, which was at one time very extensively used, and used in cases of all kinds—in real and in supposed strictures. People were made to believe, when they applied on account of any uneasiness in this quarter, that they had stricture, and a course of

Caustic Bougies

was then entered upon. A great many people were humbugged in that way, and, as I said before, were even “baugled out of their lives” in the end. DARAN was amongst the first, I believe, who thought of these bougies. The soft bougies are made of wax and resin, or ingredients of that kind, spread upon slips of cloth, and rolled up with a machine; and into this composition Armenian bole, red precipitate, and things of that sort, were wont to be incorporated, in order that the instrument might have a more powerful effect on the contraction of the passage, from whatever cause that contraction arose. DARAN thought there was a sort of wart or caruncle in the passage, and he introduced these escharotic substances, in order that they might act upon, and dry up, or corrode, the warty excrescences. Mr. JOHN HUNTER took up this subject, and he substituted for the escharotics in use, the nitrate of silver, which, however, he did not use very extensively. He, again, was succeeded by Sir EVERARD HOME, who made a very good job of it. He long enjoyed a great practice in this line, and he made a point of treating almost every stricture in this manner. Mr. HUNTER used his caustic to the anterior and the straighter part of the urethra, by means of such an instrument as I now show you, by means of what was called a “porte caustic,”—a canula, with a wire sliding in it, and a sort of contrivance for containing the caustic at its further end. Sir EVERARD HOME, again, fitted the caustic into plaster bougies, such as you here see. Here are a lot of bougies [*exhibiting an immense number*], for I began to study when the caustic bougies were in great vogue, and with these I provided myself, although I cannot say that I ever used them very frequently. The caustic is inserted into the end of the bougie. Copious directions were given as to how it is to be put in safely, and so on. It seems that the position of the stricture was first ascertained by a soft wax bougie, whether white or black is of little consequence, and then a mark was made on the caustic bougie, corresponding with that on the other; the caustic or “armed” one, as it is denominated, was then slipped down, and held in contact with what opposed it, for a minute or less, according to the determination of the patient or the operator.

This practice has been again revived by DUCAMP, LALLEMAND, and others. What I here, again, show you, are some of the instruments which have been invented lately for the purpose. They consist of a straight or a bent canula, with *porte caustics*, which are to be passed through the stricture, so that the caustic may be applied to one side or the other. There are little cavities in which the caustic is put. One part of the apparatus is carried down to the obstacle, and that part is pushed through it. The caustic is thus applied to whatever side of the canal is *supposed* to be most diseased. Here are others, for taking an impression of the part previously. This is just a return to the old-fashioned absurdity of measuring to ascertain the site of the stricture,—getting a mould of it, and then pretending to burn it out,—a capital way of picking people's pockets you may depend upon it. This caustic did, undoubtedly, sometimes do good, because when nitrate of silver is applied it will diminish the irritability of the part, and sometimes the patients passed their water easier, and the bougie slipped more readily through the stricture afterwards. The remedy was all very well when employed in this way, lightly and seldom, so as to diminish the irritability of the canal; but when it was applied with a view to drive a mine through the part, to destroy the living stricture, why then it did a great deal of harm. I don't mean to read all the books to you which I have here, but I have brought them in order to let you see the sort of practice that was pursued when I began to study. Here is

*One of Sir Everard Home's Caustic
Bougie Cases,*

for an example, and if no great good was done to the patient by this practice, depend upon it it was very advantageous to the practitioner. The case is one of many of which the book is made up. The patient, a gentleman, had had a clap when sixteen years of age; the inflammation was very severe, and lasted nine or ten months; then a gleet came on; he used astringent injections; the discharge stopped, and the urine was voided with difficulty. The gentleman then applied to Sir EVERARD HOME, who examined the urethra with a bougie, and applied the caustic. Up to a certain time the caustic was applied fifty-one times; then, again, from October 1796 to October 1797, it was applied one hundred and ten times; then the patient went into the country, and had it applied thirty-eight times. This is related in a book which Sir BENJAMIN BRODIE recommends as a very valuable and excellent work! I do not know whether he recommends the practice now or not. He used at one time to talk in commendation of it, if I mistake not, but in his own book he passes over the subject rather

lightly; in fact he seems to give it the go-by. The caustic was then applied, from the 5th of January to the 26th of August, one hundred and two times. In another year it was applied one hundred and forty-eight times,—a pretty source of revenue at a guinea a time, I should think. From November to the end of June forty times. In all four hundred and eighty-nine times in this one case! But there are some other cases equally good, if not better. This patient continued free for some time from any relapse, but he was still under the necessity of passing a bougie *daily* into the urethra, and leaving it in the canal for half an hour at a time, to keep the canal in a state of freedom. Now who will be bold enough to call this a cure? Why, after all the four hundred and eighty-nine applications of caustic, he was under the necessity of using a bougie from day to day! A pretty account this, from the surgeon's own mouth, of the success of the practice which he recommends. Yet for years such proceedings were lauded, and nothing would go down but treatment by caustic bougies.

But this has given way to another piece of nonsense, I can call it nothing else,—the cutting of the strictures from within, the using of

Cutting Catheters,

which are not a whit better, or more safe, than the caustic, depend upon it. This practice has been recommended by various surgeons, and I now put before you the various apparatus of those different people. Here, in the first place, is that of AMUSSAT: it is composed of a straight silver bougie, in two parts, joined by a screw. This is passed through the stricture first. (You know very well, that when we can get an instrument like this through the stricture, we consider the cure to be all but complete.) Then the canula, with cutting edges at its extremity, is pushed over, the penis being grasped and pulled forwards, so as to put the urethral canal upon the stretch. The instrument is constructed to cut the internal parts, in the same way as a stricture in the rectum has sometimes been cut when it is unyielding. It is no bad notion, but still it may prove injurious, and it is a practice which is not required. This instrument I had from AMUSSAT himself, and is one which I saw him use. Here, again, is another contrivance of the kind, which is called a "jacketed stilet." It is a catheter, with a *socket*, which can be made to protrude at its point. It is a very dangerous sort of tool. Indeed I do not know who would choose to have this introduced into his urethra. It must be a highly dangerous proceeding in the hands of any one, however dexterous he may be. Here is another of these machines. This small catheter is to be passed, with the wire in it; the catheter is then withdrawn, the

wire being left; the wire is then carried through the centre of this cutting instrument, and is intended to serve as a guide to it. It would be all very well if you had any means of fixing the farther end of this wire. If you could but put your fingers in any way into the bladder, and lay hold of the wire, then the conductor would be perfect, and you could push the double lancet down, and divide the parts safely enough. There are other machines of the same fashion; here is one of LALLEMAND's, and I think it is safer than most of the others. A little lancet is protruded, and the stricture is cut, either by pushing the instrument forward, or in withdrawing it,—all very pretty things to look at, and very useful to the instrument-makers, who of course approve of them; but not so to the patient, as he finds, in the end, by sad experience.

Now in slight cases of stricture, none of these plans by caustic or by cutting can by any possibility be required; and in bad cases no good can result from them. If you could succeed in boring a hole with caustic through a contraction,—and you might do so, were you to use the kali purum, the infernal stone, as it has been called, and which has even been recommended by some innovators and schemers, you would not benefit the patient,—you would certainly leave the patient after great suffering, in a worse state than you found him. Great and imminent dangers arise from the use of any caustic. There is risk of hemorrhage, of rigors, of false passages, and I cannot tell you what else.

But even if you could succeed in passing through the obstacle, you would leave a large internal sore behind, and what are you to expect from the cicatrization of that? Why a worse contraction than existed before. The same observation might be applied to the employment of the cutting instruments. No good can result in a very tight stricture, by dabbling at the near end or commencement of the contraction, with any of them. You would no doubt make a breach of surface in the membrane lining the passage, but you would not succeed in getting through such strictures, as you see in these specimens or drawings,—such as those which patients in the hospital labour under—strictures involving an inch or more of the urethra. You produce, perhaps, a solution of continuity in the inner surface of the canal, and you must have a cicatrization and contraction, in consequence, in that part. Moreover, your patient will very soon labour under a worse stricture, one more tight, confirmed, and unyielding, than you first found him with. I am astonished that some of the clever people who have turned their attention to this subject should not have thought of employing a “punch,” as it is called, on the end of the catheter, and taking a bit out of the canal, as clean as a

whistle, scooping it out as you would the eye of a potato. It might be called the “terebated catheter.” We shall have something of the kind invented, no doubt, and made a fuss about. Some of you may take the hint and publish a book on the subject. The name is at your service, and you might get a good deal by it.

Now these bougies for burning and cutting you are certainly not warranted in employing in ordinary cases of stricture, and in cases of tight stricture, and all cases of stricture involving a considerable portion of the canal, they cannot possibly be applied with any advantage whatever. What are you to do then? I would have you proceed in the way you have seen cases managed in this hospital. Some of them have, I am sure, been turned out cured after a very short process. I would have you attempt to get an instrument through the contraction, and if you succeed in your object, however small the instrument may be, you will ultimately have but little difficulty in overcoming the disease. I am talking of bad strictures now, such as I showed you preparations of the other day; such contractions as you see in some of the preparations in museums in which punctures above the pubes, and punctures in different parts of the bladder, have been resorted to. I have none such in my collection. You are, however, to try to pass an instrument, and if you succeed, as I have said, in getting one through, however small the instrument may be, the cure is completely within your grasp. A great deal of care and caution is necessary in the introduction of instruments in such cases. Sometimes you may be foiled in passing an instrument in the first instance, but if any water come through at all, if the bladder be capable of relieving itself in any way, you are not to be disappointed; at least, if you have gone about it gently, in general no bad effect can result. You will attempt the introduction at another time, and perhaps succeed at last in getting one through, and there you would retain it.

Proper Catheters.—Mode of Use.

The instruments which I should recommend to you in tight and bad stricture, are catheters, such as I now hold in my hand, pretty firm and well tempered, which will not bend and yield readily. You may use them of any curve you please, the less bent the better. These are good old-fashioned catheters with large metal rings, by which you have quite a sufficient hold. They are far to be preferred to the new-fangled tools with wooden handles, well furrowed, in using which you lose the advantage of that delicacy of touch by which alone you can guide the point of the instrument certainly and safely to its destination. I must say I do not fancy any instrument whatever with a rough handle, and far less sounds, staffs, and ca-

eters, which are intended to be passed into deep hidden parts, and the safe conduct of which depends upon the motions of the fingers, regulated by the feelings communicated through their nerves. In looking over the stores of instrument makers, one would be led to suppose that the different cutting and boring machines had been contrived by some very nervous and shaky gentleman who was obliged to hold on like grim death, lest his finger and instrument in his excessive agitation should part company. You must begin with a small one. You will pass it down, and probably get it through the first contraction, by which you will find it firmly embraced. You may overcome the resistance thus occasioned, and find perhaps that there is a second contraction farther on. You cannot with any very great safety pass forward the catheter, because you are uncertain whether the resistance is offered by the grasping of the first stricture, or whether it is owing to the opposition of the second one. You retain the catheter for a little while. If you are anxious, and it is an object to get the catheter into the bladder at that time, you may withdraw the first instrument, and then try one of half the size. That will not be held by the first stricture, and you will then probably get it readily through the second, and lodge it in the bladder. But you will recollect that there is a dilatation always behind the stricture, and you must be exceedingly cautious in passing it through the prostatic portion of the urethra. The ducts are always increased in size, and if you do not take care, the catheter may get entangled in one of these, and if you persevere in pressing it forward, you may do a mighty deal of harm. You should pass your finger into the rectum as a guide, not with a view of changing the position of the point of the instrument; that you cannot do; but with the intention of enabling you to ascertain exactly what direction it is taking. You withdraw the catheter a little, and pass it on again, if there be a resistance, until you succeed in lodging it in the cavity. The passing of the water of course affords evidence that all is right.

Now, as I said before, you may find it impossible to pass the instrument in the first instance, but you are to try it again and again, and at last you ought to succeed. If any water comes away at all through the urethra, although it may be in a very shabby way,—by mere drops,—you ought to succeed in getting the instrument into the bladder. I have, in two or three cases, where water was passing away, been very much afraid, lest I should be called upon to cut into the urethra behind the stricture. You may be called upon to do so in cases where you have been foiled in passing the instrument through the urethra. But I think that

When there is Complete Retention, there is less difficulty in passing a Catheter

than when the bladder is capable of relieving itself, because then there is a straining of the bladder. The urethra behind is considerably distended and enlarged, and there is less difficulty in finding the canal behind the stricture, than there is when there is no retention of urine. I should say, that sometimes, even where no water has passed at all, for a long period, through the natural canal, you may succeed in getting the catheter through. I have had to treat some very bad cases at one time and another. I mentioned to you a case the other day, that of Martin, who stated that he had passed no water for some time before he came here. Mr. Hay, one of the very many diligent pupils at this school, had seen the patient a considerable time before he came in, and Mr. HAY's account agrees exactly with my impression, that the patient had not for a considerable time passed any water at all through the urethra, but yet you saw that by perseverance the catheter was at last got into the bladder. I have before me the notes of a somewhat similar case, written by the patient himself, in which he says, that in the latter end of 1826 he had a stricture. He went to a warm climate, and a short time after his arrival he got stricture so badly, that he could not make water at all, and it was drawn off regularly. In the year 1829 he placed himself under the care of a practitioner in this city (London), and to all appearance got well. He returned to India again, but became so bad in 1835, that none of the medical men could pass the smallest bougie, and his water came away merely by drops, with the most excruciating agony, the desire to urinate coming on every ten minutes. From the external opening of the urethra to the entrance into the bladder, the parts, he says, were swollen enormously. He was told that he laboured under disease of the prostate. Indeed, it is astonishing how many practitioners fall into the blunder of supposing that young men are labouring under that affection, for it is only in old age that the sort of hypertrophy, or enlargement of the prostate, takes place. There is no disease of the prostate gland in young men; the obstacle is generally situated further forward. He was sent home, and was so ill on his voyage, that for the last nineteen days in August, he states that he could not make a single drop of water, and superadded to the retention of urine was suppression of urine. The functions of the kidneys must have been suspended, otherwise serious local mischief would have taken place, and that other bad consequences did not occur is astonishing. A swelling formed behind the scrotum, and burst; an abscess had formed in the perineum, and he was relieved. Upon his arrival in this country he applied to medical men in his neighbour-

hood, but they could not pass any bougie, and for two months before he came to me, not a single drop of water had passed through the urethra. He could not retain water; it was running from him at all times, and occasionally violent spasms came on, of the most excruciating kind; there was violent straining of the bladder, and of the muscles that are concerned in emptying it. In that case a catheter was got through the first stricture with no very great difficulty. I could not succeed in passing it to the bladder at first, but I assured him that every thing would go on well, and begged of him to retain it in half an hour; I returned and withdrew it, and at the same time took the liberty of passing one, a little less in size, through the second contraction, into the bladder. This catheter was retained for forty-eight hours. That was taken out, and one of about double the size was introduced. The day after, a full-sized catheter was passed into the bladder without difficulty. It was withdrawn, and he was allowed to rest. In two days the catheter was reintroduced readily. Since then it has been passed four or five times, with an interval of five or six days, and having regained his health and strength, he now walks about and amuses himself, having completely recovered all the functions of the parts; the openings have nearly healed up, and he will soon be perfectly well. As regards the fistulous tracts and openings in the perineum and scrotum, the removal of their cause (the obstruction of the passage in the great majority of cases), suffices for their cure—they gradually cease to give exit to urine; it passes slowly, then in drops, as the stream through the natural passage improves, and, finally, both that and the purulent secretion cease entirely; the hardness gradually disappears. It may be now and then necessary to dilate the openings a little, to foment, and enjoin rest, if, after the introduction of a bougie, pain or swelling should supervene. In some few cases, when perhaps the whole of the urine has found an exit for months through a false passage, and when that does not close after the urethra is put into good order, you may be called upon to employ means to promote and hasten the closure of the sinus. In those cases, in which a communication has been formed with the bowel, also, further proceedings are called for than a "course of bougies." You may have to retain a catheter for some time, though, occasionally, ulceration is produced or kept up by a foreign body in the urethra. The means most effectual, and by much more to be depended upon than real or supposed caustics, is the application of a heated wire, and that is almost the only use in surgery,—those false passages about the male or female organs,—in which, so far as I apprehend, the actual cautery can be justifiably employed. We can, when some

would have recourse to its use, attain our object more speedily and effectually by less painful and much less appalling methods. Here, however, the extent of the cauterization can be more certainly regulated, and the contraction which follows is more complete than that which follows any potential cautery. If a repetition of the application is called for, a sufficient interval must be allowed to elapse betwixt the operations. The contraction must be allowed to go as far as it will do after one touch of the wire, before it is repeated. As yet we have had no trouble with those cases of fistula in perineo which you have seen treated in this hospital, and these have not been few since it has been opened for the reception of patients.

(To be concluded.)

LECTURE ON THE HISTORY OF HYGIENE.

Delivered in his Course on Hygiene, at the Lecture Room, 8, Grafton Street, Fitzroy Square,

By WILLIAM FARR, Esq.

Travels of Hippocrates.—Philosophy of Life and Death.—Defects in the Ancient Medical Classics.—Climate of Greece.—Epidemics.—Cases reported by Hippocrates.—Errors of Diseases; real Signification of this Doctrine.—Diseases have a determined Duration.—Diseases terminate naturally in Recovery.—Philosophy of Diet.—Relation between Diet and Exercise.—First Signs of Excess in Food.—Adaptation of Diet to the Seasons.—Influence of Climate on Man, physiological and pathological.—Changes of Climate advantageous.—Influence of Social Institutions.—Proofs that the Hygienic Department of Medicine, cultivated with so much care by Hippocrates, may exercise more Influence on the Health of Mankind than Drugs.

GENTLEMEN,—The architecture of the Greeks, their poetry, history, and philosophy, have been understood in this country, and are regarded with reverence by their equal and natural judges; but how do we regard the medicine of the Greeks? Are we as well acquainted with the works of Hippocrates as the artist is with the creations of Grecian sculpture? We know his name; the cyclopedists trace many fantastic doctrines to his works; a quotation now and then crosses our path; but what is our present conception of the essential principles he taught? His words are on some of our

lips, but is the philosophical physician's spirit therefore in our hearts? Among many he appears to be in very low esteem. A member of the Council of the College of Surgeons, in his evidence before Parliament, said,—“I believe that neither Hippocrates, Galen, nor Celsus, would obtain our diploma: they would all be turned back in five minutes by either the College of Surgeons or the Apothecaries' Company.” Dunces, you know, are sometimes kept up half an hour in Lincoln's-Inn-fields; but the insufficiency of Hippocrates would be apparent in five minutes. He would inevitably be “turned back.” This was spoken by a gentleman of “infinite jest;” yet it is probably sober truth, and shows how great men may be treated with contempt where their greatness is forgotten. A good English translation of the works of Hippocrates a better knowledge of Greece, and a higher tone of thinking, will, no doubt, in the end place the medicine of the Greeks in the same advantageous position as their other arts.

In inviting you to examine with me the doctrines of Hippocrates, in whose mind the hygiene of civilization first assumed a consistent form, it is not from any desire to enforce them by a superstitious regard to antiquity or authority; but in the hope of being able, after familiarizing our minds with great and accurate thoughts, to apply with greater success to the investigation of Nature.

HIPPOCRATES, born in Cos, a small island on the luxuriant coast of Asia Minor, was the second of that name, and inherited all the accumulated wisdom of an ancient family of the Asclepiade. His career commenced 460 years before the birth of JESUS CHRIST. He travelled through several states of Greece, spending his time chiefly in Athens, Thessaly, Thrace, and the island of Thasos; he visited many of the neighbouring people, and after attaining great glory in that country and among his disciples, retired to Cos, to devote himself to his writings. In this island, or at Larissa, he died, aged eighty-three years. It was the time of the Peloponnesian war,—the age of PERICLES and SOCRATES.

HIPPOCRATES was not the author of all the works now printed under his name; he wrote but few himself; others were committed to writing and extended by his followers, or they were the productions of his family. I proceed to develop his views of hygiene from the more authentic documents, as they form a more enlarged system of health than has ever been conceived by any other man. In general I have followed the admirable Coray in the translations, but if I have in any cases mistaken the sense, I shall thank any one who may be a good Hellenist to put me right.

HIPPOCRATES, as the basis of his philosophy, lays down that life and organization,

and health and death, are but states of matter; that the birth of one body is the death of another; that the composition of one is the decomposition of something pre-existing, and that matter is eternal in its properties. No body is destroyed, or can become what it was not before, or can be formed from nothing. To be produced, and to be destroyed, to be born and to die, are the same thing,—combination and decomposition, changes of form. Men think that what springs from invisibility into light is created, that what passes from light to darkness, perishes; but we must believe the evidence of our own eyes rather than unevincenced opinions. All things human undergo metamorphoses, increase and decline to their maximum and minimum, as the sun and moon, as light and darkness. In its changes, everything, great or small, fulfils its fate, willingly or unwillingly, by divine necessity.

In examining the doctrines of HIPPOCRATES, we must never forget—although the anticipations of his genius sometimes tempt us to forget—that he was the first who devoted himself exclusively to the study of physiology, and to the cultivation of medicine. The nature of man, his organization, his relation to the external world, and the causes and remedies of his multitudinous diseases, when first opened to investigation, revealed questions enough to overwhelm the mind with confusion. Should we, then, he astonished to find errors in the Hippocratic writings,—particularly on anatomy, and on subjects which the prejudices of the Greeks and the want of instruments prevented him from examining? His discriminating genius is discoverable in the direction of his mind to objects within reach, and of most pressing interest to humanity; the imperfection and uncertainty of his principles resulted from the want of instruments for measuring phenomena. He had no barometer, no thermometer, no hygrometer, so that all his observations on temperature and moisture are indeterminate; he did not employ enumeration to measure the duration of life and disease, the proportion of sickness, the various forms of disease, and the deaths in all ages and under all circumstances; yet in a great many instances he has predicted what calculation will prove to be correct; he has measured the evil in his mind, and foretold the remedy.

Every form of malady and death may happen to men of all races, of all ages, and at all seasons,—but the relative proportion occurring in these various circumstances is very different. Greece is situated between the 36° and 40° of N. latitude; it is traversed by the Isothermal line, 18½°, centigrade; more than nine months in the year the temperature is higher than that of spring in England. Placed on the tropical border of the temperate zone, surrounded by the

Mediterranean, bathed by the hot winds of Africa saturated over the sea, chilled by the north-east winds of the continent, or refreshed by the life-giving west, Greece, from its multitudinous shores to its lofty mountains, some of which rise 7000 feet, presents all the fruits of the tropics, intermingled with the corn and flocks of England. Many districts have no direct outlet to the sea, and the shores are marshy, which, with the heat of autumn, produces the fevers of the tropics. In January, the pulmonary affections of England prevail. Out of 15,191 diseases occurring among the English troops in the Ionian islands (1816-1821), 5721 were common, remittent, or intermittent fevers; and it was observed that while the fevers of the troops were remittent, those of the natives were intermittent. The same class of diseases, and the same difference, were observed by the French in the Morca, during their last expedition.

In the books of Epidemics (ἐπὶ upon *δημοῖς* the people) HIPPOCRATES attempted, and in part realized, the great undertaking of presenting all the diseases of a people in connection with the natural phenomena of the seasons. The constitutions of the years are determined; the winds, the heat and cold, the moisture and dryness, and the order of their succession; then the reigning morbid constitution, the mortality and the duration of diseases, the ages, sexes, and occupations most afflicted; while illustrative individual cases follow.

The term *epidemic* now designates one widely prevailing form of malady. Epidemic, in its present sense, is the *reigning disease* of Hippocrates, to which he did not confine his attention, but took into consideration, and described, all the contemporaneous types of sickness. In the late descriptions of epidemic cholera, you will find that statistical writers in England, Germany, and France, have restricted themselves almost exclusively to reporting the deaths from cholera,—and sometimes the cases. Now the total deaths or cases out of the living at each age, and the deaths from the epidemic, compared with the deaths from other causes, were the most essential and interesting elements of the problem which they sought to solve,—elements which they overlooked, and which HIPPOCRATES especially regarded.

In reporting cases, his choice was influenced by the character of the disease they were intended to represent. He neither reported merely fatal cases, as is too often done by the French pathologists, nor did he confine his relations to cures—the rock on which we often split in England. BOYLE somewhere censures HIPPOCRATES for narrating so many unfavourable cases, but this scientific candour was an element of the great observer's immortality.

From the manner in which his observa-

tions were recorded, it was easy to ascertain the periodical changes and the course of a disease. He did not reckon by days of the month, as is done in the present day, but by days of the disease, dating from the onset; he does not say on the 3rd, the 8th, &c., of the month, but on the 3rd, the 8th, &c., of the disease, such a change took place; or the malady terminated. One of the shortest cases will make this clear:—

Eighth Patient.—A young man, who slept in the market-place of Liars (Athens), was seized with fever from fatigue, labour, and unusual walking. 1st day. Stools bilious, thin, abundant; urine thin, dark-coloured; no sleep; thirst. 2nd day. General exacerbation; purging frequent, excessive; no sleep. The mind agitated; perspired a little. 3rd day. *Malaise*; thirst; loathing; great restlessness; despair; disturbance of mind. The extremities livid and cold. Præcordia swollen, softish. 4th day. Had not slept; growing worse. 7th day. Died. Aged 20.

By forming a table of such cases—perhaps without doing this—it would be easy to perceive whether the crises occurred on any particular day, or in any definite time. The crises of some fevers, it is said, happened on the fifth or sixth day; in others, no crisis took place before the 20th, 40th, or 80th day; some never came to a crisis. Fevers, in which life is destroyed or saved, terminated in the same number of days. Relative to the crisis, some days are called “remarkable” (ἐπεσσοὺς), which was translated into Latin by *impar* (odd, unequal); but means, according to good Hellenists, *unequalled, superior*. The chief critical days were the 4th, 7th, 11th, 14th, 17th, 20th.

Diseases were divided into three stages. In the first the crude morbid elements existed, in the second the *morbid product* was formed, in the third it was expelled, and this coincided with the termination of the morbid revolution. The crisis was synonymous with termination, whether by recovery or death; but it was sometimes applied to a single symptom.

HIPPOCRATES appears to have been misunderstood with regard to the doctrine of critical days; for instance, CELSUS mistakes and combats that doctrine on erroneous grounds. Some appear to think that HIPPOCRATES imagined that diseases came to their crisis, or, in other words, terminated, *only* on the critical days; how incorrectly, the following forty-one cases, recorded in the first and third books of “Epidemics,” will make manifest.

Here the crises are distributed very unequally, because they are few, and they are not confined to the critical days. It could, consequently, only be meant to affirm that, on the average, fevers ended *more frequently* on these than on other days; and this may be more obvious in the intermittent diseases of the Mediterranean than in this country.

TABLE 1.—*Crises of 41 Cases of Disease, recorded by HIPPOCRATES in the first and third Books of "Epidemics," showing the days on or before which they terminated by either Death or Recovery.*

Day.	Crises.	Day.	Crises.
2	1	17	3
3	1	20	3
4	3	21	1
5	4	24	2
6	3	27	1
7	3	34	2
10	1	40	3
11	3	80	3
14	2	120	2

But there is another sense in which the Hippocratic doctrine may be understood. He may have divided acute diseases into periods, in order to predicate when the majority of crises occurred, although the observations were not numerous. And this sense is supported in the book of "Crises," where it is said that the mildest fevers terminate on or before (*πρὸθεν*) the 4th day; the most deadly destroy on or before the 4th day. So the first access (*φόβος*) ends. The second extends to the 7th, the 3rd to the 11th, &c. I therefore think we may admit that acute diseases were divided into weekly periods, and that these were subdivided into intervals of four and three days, as half a week could not be expressed in entire days (*δλαις ἡμέραις*). The foregoing forty-one cases, thus arranged, would justify us in saying concisely, that the crises took place on or before the 7th day, and that the diseases in question were judged by the 20th, as ten cases ended in the second period (*πρὸθεν*), and only thirteen out of forty-one remained at the end of the third week.

TABLE 2.—*Weekly and Half-weekly Crises of the preceding 41 Cases; 24 of which were by Death, 17 by Recovery.*

Week.	Between Days.	Half weekly Crises.	Weekly Crises.
1	{ 0—4 4—7 7—11 11—14 14—17 17—21 21—24 24—27 34 }	{ 5 10 4 2 3 4 2 1 1 }	15
2			6
3			7
4			3
5			2

The eight remaining cases terminated on or before the 40th, 80th, or 120th day.

Whatever the Hippocratic doctrine may be, it is certain that in this country, in France, and in Germany, few diseases terminate on particular days, or at one period; but I shall be able to show you, that the termination or crisis of several, and probably of every disease, takes place according to a determined law, which may be at any time deduced, when the observations are sufficiently exact and numerous. Dr. LATHAM has reported 297 cases of typhus fever, to refute the Hippocratic notion of critical periods,—to show that the crisis of that disease is irregular, and subject to no law. When properly arranged, they prove exactly the reverse:—

TABLE 3.—*Crises of 297 Cases of Fever reported by Dr. LATHAM; who does not state how many died or recovered.*

Day.	Crises.	Day.	Crises.	Day.	Crises.
5	2	24	10	42	4
6	3	25	6	43	2
8	3	26	4	44	3
9	6	27	7	45	1
10	3	28	8	46	4
11	12	29	4	47	1
12	13	30	11	48	1
13	12	31	11	49	8
14	8	32	6	50	1
15	9	33	8	51	1
16	14	34	6	53	2
17	12	35	5	55	2
18	16	36	1	56	1
19	8	37	—	57	2
20	9	38	3	59	1
21	8	39	5	60	1
22	7	40	8	62	1
23	9	41	3	65	1

In looking over this table, it may be supposed that the 11th, 12th, 13th, 18th, 24th, 30th, 31st, and 49th, were critical days, as the great number of cases terminated on those days; but this irregularity is owing to the small number of facts being divided into a great many sections. If the cases were more numerous they would terminate regularly, as in Table 4; where longer spaces of time are employed:—

TABLE 4.—*Showing the Weekly Crises of 296 Cases of Fever.*

Week.	Crises.

Mean duration 3½ weeks.	

HIPPOCRATES WAS well aware that the majority of patients recover from disease; that the majority of fevers, inflammations, and other severe maladies, seldom destroy more than a fraction of those attacked, when left to pursue their unobstructed course. In Corfu, where the annual deaths were 274 per 1000, only 23 died out of 1000 attacks from disease of all kinds, sufficiently severe to send the soldier to the hospital. I never saw this calculation made for England; but I think it furnishes an approximation to the general truth. The patients were treated, and the deaths were no doubt considerably diminished by medicine; but without any treatment, if 42 out of 43 had not survived, the great majority would have recovered. The natures of diseases are the best physicians (*Nature quæritur in ipso*): wherefore HIPPOCRATES scrupulously observed their natural evolution, all the changes, and the increased excretions which accompanied their progress to health; and where *unfavourable accidents occurred*, and threatened the extinction of life, he opposed them, by endeavouring to induce the natural crises,—to bring cases, precipitated by something into a fatal route, back to the *natural* course of those ending in recovery.

The Hippocratic doctrines of diet present a philosophical outline of that department of hygiene. A writer on the diet of man, it is observed, should be acquainted with the nature of the whole body, its organs, and the subordination of its powers; should be acquainted with the qualities of all food and drink in the natural and in the prepared states; should know the way to dilute strong things, and to make the weak stronger, by art, as occasion may arise. Nor is this enough; for a man cannot be healthy unless he works as well as eats. Food and labour are opposite forces, which, when in accord one with the other, constitute health; for health is perfect when the elements of the body exist in due quantity, power, and composition (*crasis*). Labour consumes the principles supplied by food; therefore it behoves us to determine the force of labour, both natural and violent,—such as gives, and such as takes away flesh; also the relation of labour to the quantity of food, to the constitution of men, to the size and age of the body; to the seasons, the winds, the site of the country in which they live; to the prevalent type and to all the causes of disease. He who could discover an exact measure of the relation between labour and food, would detect the secret of human health. But this is impossible: they cannot be made symmetrical; yet, as when one is a little defective, the other force runs into excess, there are means of detecting the excess of either, before the slowly-accumulating disease bursts into a flame.

In the application of hygiene it is of the utmost importance to be able to distinguish

the first aberrations from health: these are *leminously treated*, probably from observation in the gymnasia. The first signs of disease from *repletion* are, 1. A stuffing in the nose after dinner, with a secretion of mucus and saliva on the following morning; heaviness of the eyes, paleness, and loss of appetite. 2. Long and agreeable sleep, sleep in the day, followed subsequently by troubled dreams. 3. Lassitude; pains of the whole body, or of parts of the body. Heaviness and headache; the eyelids dropping after dinner, and convulsed in sleep, heat, and sometimes costiveness. 5. Flatulence, voiding the aliment soon after eating, which seems to yield relief, but is soon followed by heat, and diarrhoea, or dysentery. 6. Crude, but not acid eructations; scanty stools compared with the food, yet really copious, with no internal pain. 7. Pallor and acid eructations shortly after eating. 8. Acid eructations on the following day. 9. Profuse perspiration in the first sleep, suffocation, heat, vomiting. 10. Liquid stools, without pain; wasting. 11. The food passing away undigested, but not putrid; wasting. 12. Watery putrid stools, without other inconvenience. 13. A dry, and in process of time, a bitter mouth, confined bowels, hard dry stools, ending in stercoraceous vomiting. — *Exercise is excessive* where headaches and shivering come on after the morning walks. Some shiver in the gymnasium, from the time they strip till they begin their exercise, and on cooling, their teeth chatter; they are sleepy, and when awoke they feel giddy; their eyes are heavy; malignant fever supervenes. Labour has exceeded food.

The regulations respecting seasons hold still in Greece, and require little modification in England. In WINTER eat once a day; lunch very moderately. The food should be dry, rich, heating. Do not go through a gymnastic training in winter; the trees which have not wintered bear no fruit, nor are they healthy. Warm the body with labour, to promote perspiration. Day is short, night long, and this teaches us that labour should be neither long nor excessive.

— SPRING. When Arcturus arises, when the south winds blow, and the swallow comes, food, drink, and labour, should be more varied, milder, and lighter. As about the equinox (March) the days are lengthened, the nights shortened, the season is warm and dry, diet should be nutritious and rich. The trees, devoid of reason, provide themselves in this season with increase and shadow, against summer; so should rational man prepare a healthy accession of flesh. In SUMMER the food should be softer and more sparing; drinks mild and diluted; luncheon moderate, and the siesta brief; excess in meat or drinks as slight as possible. Sexual intercourse should not be indulged. Tepid bathing may be used. Avoid the sun, and

the cold morning and evening vapours, exhaling from rivers, lakes, and snows. At the summer solstice take no dry, hot, rich things. **Autumn**.—From the equinox (September) guard against extremes of heat and cold by thick clothing; walk out on warm days; use tepid ablutions; warm and dry food.

Many of the aphorisms are useful general guides in diet, such as, "Beware of sudden changes in living;" "The hungry should not work;" "Those who feed fast and suddenly, may be suddenly reduced;" "Those who waste slowly, are restored slowly;" "The more that unsound bodies are fed, the more they are injured;" "There is more danger in living on a weak and strict, than on a rather full, diet;" "A high state of gymnastic training is dangerous."

The atmospheric origin of some diseases was recognised by HIPPOCRATES: the nature of man cannot always resist the power of the universe; and certain conditions, constitutions, and climates, impress a peculiar form, not only on disease, but on the entire organization and character of the human family. These are treated of in the book of "Winds, Waters, and Places," presenting a physiological view of the principal races of men observed by him in Asia and Europe, developing their innate energies, such as they were fashioned by the earth, and subject to the diseases induced by the external elements. This book is a perfect model of physiological delineation. PHIDIAS, or ZEUXIS, never sculptured the human figure more divinely, or painted with more expression, than HIPPOCRATES has here traced the Asiatic and European character.

The influence of the earth on its human inhabitants, is expressed somehow in this manner:—You will almost always find the forms of men and the nature of a place, corresponding; for where the soil is rich, and soft, and wet, and of uniform temperature, the people are gross, lymphatic, of relaxed joints, intolerant of toil, and cowardly; indolent and sleepy; they are neither keen nor subtle, but dull in the arts. On the contrary, where a region is bare, rough, unsheltered by nature, oppressed by the cold of winter, and burnt by the summer's sun, the men will be found spare, robust, of well-expressed form, vigorous, and swarthy; they will be capable of toil, and wakeful; their manners will be pertinacious and continuations; they will be easily roused to anger; fiercer than mild; exceedingly acute and dexterous in the arts; expert in war. For whatever springs from the earth, savours and participates of its nature.

To great changes in the weather, and sudden irregular successions of heat and cold, moisture and dryness, HIPPOCRATES attributed great power; he considered them the most common causes of disease, and often states that slow alterations of habit,

diet, and temperature, are alone perfectly safe. In the mild, equable climate of Asia, every thing grew in greater size and beauty than in Greece; human manners were more benign and refined; at the same time the inhabitants were rendered timid, effeminate, indolent, and unwarlike. The atmosphere around them lay tranquil, and was insensibly changed; hence the soul was never shaken, the body never tossed about, and tried by changeful vicissitude, which probably exasperates passion, and excites heat, and intellect more than repose. For changes always rouse the mind of man, and permit it not to rest.

When the organization is thrown into motion by the external forces of nature, and then suddenly abandoned to its own resources, an effort of *self-action* is made, which gives and concentrates independent power; and thus Nature bears her children, as on eagles' wings, into the higher regions of exertion, and educates them till they can triumph over their element, and ride upon its storms. Excitement of the mind, and of animal heat, which have many analogies with each other, is equally favoured by changes of temperature. We may conceive that in a cold atmosphere a great supply of internal heat is demanded, and when the atmosphere becomes warm, the supply will be superabundant; and this principle of reaction not only applies to calorification, but to the muscular, the nervous, and all other organic functions. In the political changes, the stormy years, of the Peloponnesian war, Greece produced many of its immortal works. Man is ever seeking an equilibrium, but that is repose and death. When the equilibrium is most disturbed, he is most active. Variations in the intensity of external agents serve not only to augment the sum of power, but they temper the body, and fit it to live through a greater range of circumstances; they improve its means of *self-adjustment*—a point which requires deep consideration in education. Medical men, when consulted relative to the regimen of children, and even of adults, are too apt to recommend exclusively warmth, regular diet, and exercise, proscribing all extremes. This may prevent tender children now and then from taking cold, but, on the whole, more is lost than gained by it. Let us never forget that all men are often hurried from one extreme to another by necessity, and that this sort of oscillation preserves or accumulates vital force.

There is a limit to the utility of change. It may be excessive. HIPPOCRATES was speaking of the climate of Asia Minor and Western Asia compared with Greece, crowned indeed with snow-covered mountains, but situate in a latitude where the general range of changes only extended from the temperature at which corn would grow to that at which the grape, or orange, or olive, would

ripen. In countries not known to the Greeks, in Pekin and Petersburg, excessive change is little more favourable to life than the uniformity of the habitable parts of the frigid zone or the tropics.

One general principle limits another; the climate may be good, but the government may be bad; or the race may be feeble. So HIPPOCRATES further attributes the unenergetic character of the Asiatics to their laws. The greater part of Asia is, he says, governed by (despotic) kings; and where men are despotized, are not in their own power, and do not live under their own laws, they are not very curious in preparing for war; nay, they rather take care to appear unwarlike; for, to them the chances are unequal. They are driven to fight, to toil, to seek death, for their lord, while their children, wives, and friends, are left behind; nay, if they bear themselves valiantly, and are successful in battle, the advantages accrue to their lord, and augment his resources, while to them nothing is meted but dangers and death. Their lands, too, are liable to devastation, or to be made desert by the enemy and by the cessation of labour, so that brave men are prevented by the laws from exercising their courage. The influence of government is further proved by this: wherever the Greeks, or barbarians in Asia, live under their own laws, fight for themselves, and reap the fruit of their own labours, they are neither cowardly nor indolent. It may be added that experience has since shown that they for a time could become both, in the stirring atmosphere of Greece, under a despot. Thus has our great author laid bare the very nerve and withering arm of despotism. Independence enlarges, and gives energy to, all the faculties; it is the vital breath of the mind; it gives health to a nation; and we shall have occasion to show that life is not only less valuable, but, on the whole, shorter in Austria and other countries, where paternal governments enforce hygienic laws, but deprive their subjects of liberty, not allowing them to bring up children *for themselves*, than in England, where the government has attempted so little towards raising the population to its present pitch of vitality by direct enactments.

In fine, all modifying agents act less on the individuals existing than on those forming, and Europeans differ from each other more in size, form, and faculties, than the Asiatics, because—"Phures corruptiones contingunt in seminis coactione quum tempera sequenter variant, quum si eadem sunt et similia."

HIPPOCRATES has described all the forms of sickness, and the signification of every sign, with an unapproachable exactness. He would have estimated the pathological discoveries of BAILLIE, MECKEL, LAENNEC, LOUIS, and CARSWELL, at their real value,

but the day for them was not then come. Bleeding, and strong purgatives, and other active remedies, he did not spare to employ, as occasion required, but HIPPOCRATES never forgot that drugs were subordinate agents in the preservation and restoration of health. He looked to climate, diet, and exercise, as causes for the prevention and cure of disease; and only considered drugs as useful auxiliaries. His practice in fevers has been called inert. What would calomel, and leeches, and bleeding, have done? The experiment has been tried in the Mediterranean. HENNEN says that the *proportion of deaths among the Russian, French, and English troops in the Ionian islands was nearly the same, although the English met the fevers of the country with mercury and the lancet "in all the activity and all the orthodoxy of the schools."* When the French army, 14,000 strong, was in the Morea, 1000 men were lost chiefly by fever in the course of nine months; *gastro-enterite* was recognised,—leeches were there—but the patients died exhausted after their use, as the troops were exposed to miasmata. Where the hygiene of an army is judiciously regulated, the soldier may be kept in health and vigour; but allow an ignorant general to encamp on a marsh, let filth stagnate, fatigue excessively the men, crowd them in low damp rooms, and, despite drugs, they will fall as unripe and blasted fruit, not by the sword but by the fever. The French and English troops at home,—not trained to the field from childhood as the Spartans were,—are very skilfully and efficiently supplied with drugs, yet their mortality in peace is much greater than that of people generally of the same age, because they violate the laws of hygiene.

Now, an army is only a part of the community; and the same facts hold of the inhabitants of a city or a small village. A medical man always saves many lives and much time in sickness; but in a neighbourhood, or in families where he can command all the resources of hygiene, his practice must be much more successful among adults, and rescue twice as many children from inevitable death, as a mere druggist who prescribes most adroitly. Officers of dispensaries and hospitals will bear this out. "But," some may say or think, "we live by drugs; the present public will pay nothing for our sanitary precepts; they know more of large green, purple, and red glass globes, than of the physiology of health; they think more of Morison's murdering pills, or St. John Long's caustic liniments, than of minute precepts about the air and food by which they live and breathe. Besides, why study hygiene, when, by promoting the general health, it would diminish the number of patients?" Gentlemen, I know that you—I know that our generous profession—will not, for a moment, harbour sentiments

base. We exist, as a body, to promote the public health, and if the persistence of our craft is at variance with the public good, in the name of God let it be abolished,—let us betake ourselves to something else. Happily our interests are the interests of the community: in proportion to the health and strength and knowledge of England, it has flourished, and will flourish, and in its prosperity or reverses we shall participate. In patriotism, also, HIPPOCRATES was our pattern. He pointed out the sources of health and improvement to mankind. He remained to the last, true to the fortunes of the small island on which he was born; he refused to go to the court of Persia, because he preferred serving Greece, and his disinterested exertions during pestilence obtained for him a place in the Prytaneum of Athens.

HOPITAL DES ENFANS MALADES, PARIS.

RESEARCHES INTO THE DISEASES OF CHILDREN,

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND PATHOLOGY.

TUBERCULAR MENINGITIS *

Child ten years old; symptoms of tubercular peritonitis; headache, returning with irregular access, and sometimes accompanied by bilious vomiting; dullness; morosity; after three months, constant headache, bilious vomiting; numbness of the limbs, delirium, coma, general convulsions; death at the end of seven days; tubercles found in the meninges, lungs, bronchial glands, and peritoneum.

CASE 3.—Clemence Fournier, an orphan, ten years of age, was attacked at the age of seven with confluent small-pox, of which she still carries the marks; for the last three months she has complained of pains in the head and abdomen. Admitted into the hospital on the 14th June, 1835. She did not present anything more than the symptoms of tubercular peritonitis, and some uncertain signs of pulmonary consumption; up to the end of June we did not observe any notable change in her condition, beyond a sadness and depression of spirits that seemed quite disproportionate to the patient's sufferings, and two or three attacks of headache, without any other trouble of the cerebral functions. During the last few days of the month the moral and physical depression became more and more severe, with intense headache, and slowness of the pulse. *Leeches behind the ears.*

July 5. The headache has disappeared,

but the patient is dull; she keeps the eyelids constantly closed; when roused from the sleepy state in which she lies, she answers correctly; no convulsion or paralysis of the limbs, but the muscular force is excessively depressed; pulse irregular, 96; the diarrhoea which existed for several days has given place to obstinate constipation. In the evening, return of the headache, which the patient describes as having its seat in both temples.

6. During the night and the morning, violent delirium and agitation, rendering it necessary to employ the strait-waistcoat; at the visit, however, she answers all questions addressed to her, and puts out the tongue when required; she complains much of headache and feebleness of sight in the left eye, whose cornea is perfectly transparent, and the pupil neither contracted nor dilated. On the other hand, the surface of the right eye is bathed in a puriform liquid. The sensibility of the skin is obtuse at both sides of the body, and the muscular force greatly diminished; the patient is unable to grasp an object firmly in either hand; the head is thrown backwards, and she utters an acute cry whenever we attempt to bring it to the natural position; there is no evidence of pain occupying the dorsal or lumbar regions; the patient can sit upright without difficulty: the pulse is moderately strong, 96, as yesterday; the diarrhoea has now returned, and evacuations are sometimes involuntary. During the day, low delirium; the child is unable to recognise her relations.

7. Coma; she does not answer when spoken to; the eyelids are closed; the pupils largely dilated; the limbs are in a state of resolution, and when lifted up are seized with a trembling motion; the muscles of the neck, on the contrary, present a tetanic degree of rigidity, and render the head quite immovable; pulse 100; no stool; urine excreted involuntarily. Six leeches, three to the right temple, and three behind the right ear; a blister to each leg.

At three o'clock p.m. the patient was seized with general convulsions, which persisted for about an hour, and then terminated in death.

Body examined thirty-eight hours after Death.—Temperature of the Atmosphere, 20° R. (77° Fahrenheit).

External Habit.—Body lean; cadaveric rigidity very well marked; abdominal parietes of a greenish colour.

Cranium and Vertebral Canal.—The brain and spinal marrow had been removed from their cavities with their membranes, and left on the table of the dead-room for at least six hours before their examination by M. Jadelot in presence of the pupils. The dura mater does not present anything remarkable. The arachnoid at its free sur-

* Continued from LANCET, No. 645, page 575.

face is moist, and conserves its normal transparency; the pia mater is infiltrated with a great quantity of serosity. In its tissue we remark a great number of tubercular granulations, offering the same physical characters as in the cases already reported. On the anterior part of both hemispheres, to the extent of about a square inch on the right side, and half an inch on the left side, the pia mater is infiltrated with a yellowish substance having the consistence of chalk. This substance penetrates with the membrane into some of the anfractuosités, and here it is impossible to separate the pia mater, especially on the right side, without removing with it a portion of the cerebral pulp. Between two convolutions of the convexity, we find a tubercle, not larger than a good-sized pea; the cerebral mass is almost reduced to the consistence of jelly; but as this softening is not accompanied by any change of colour, and is general, it probably depends on putrefaction. The spinal marrow is equally softened. It does not contain any trace of tubercles.

Thorax.—Both lungs contain a great number of milary tubercles; the bronchial glands are tumented, and transformed into tubercular masses.

Abdomen.—The epiploon, thickened and studded with tubercles, adheres to the anterior wall of the abdomen, and to the convolutions of the intestinal tube, which are also united by false membranes that contain small white tubercular deposits. The sub-peritoneal cellular tissue of the intestines, the mesentery, the liver and the spleen,—all these parts contain numerous tubercles. The interior of the intestinal canal was not examined.

TUBERCULAR MENINGITIS TERMINATING IN ACUTE HYDROCEPHALUS.

Child eight years old; antecedent measles; depression of spirits, and dulness; headache and fever, returning by irregular accessions during three months; the symptoms of acute hydrocephalus; death; granulations in the pia mater; effusion of turbid serum into the lateral ventricles; softening of the white central parts; pulmonary tubercles.

CASE 4.—A young girl, eight years of age, habitually of good health, of lymphatic temperament, contracted the measles near the end of April. During the three months following the disappearance of this exanthema, which was very irregular in its march, the patient frequently complained of pain in the head; she became sad, dull, and was attacked from time to time by accessions of irregular fever. Towards the middle of July, the headache and fever became constant, with pain in the abdomen and constipation; a few leeches were applied to the arms, and mustard poultices to the extremities. The symptoms were dissipated by these remedies, and the child seemed to have recovered her original gayety and health. On

the 4th of August, however, without any known cause, she was seized with vomiting, followed by intense headache, fever, and delirium; in the night of the 5th, she sank into a state of deep stupor; on the following morning, being transported to the hospital, she presented the following symptoms:—

Dorsal decubitus: alternation of paleness and redness of the face; complete loss of consciousness; the coma is from time to time interrupted by low cries; the globes of the eye are constantly agitated by convulsive movements; the pupils dilated and immoveable; the faculty of vision completely destroyed; there is trismus, grinding of the teeth at intervals; foamy saliva, tinged with blood, issues from the mouth. The superior and inferior members are slightly rigid; the sensibility obtuse at the right and left sides of the body, equally; no nausea or vomiting since yesterday; the child passed two or three involuntary stools during the night, after the administration of a purgative; the abdomen is retracted and indolent; the skin is dry, flaccid, and rough on the limbs; the heat moderate; pulse small and irregular, 132; the respiration accelerated, 52 in the minute, and often accompanied by dilatation of the nostrils. The chest gives a normal sound under both clavicles: on auscultating the patient we hear nothing but some mucous rale. *Twelve grains of Calomel, in four doses; a large blister to the head, and sinapisms to the lower extremities.*

At two o'clock p.m. the cries had entirely ceased; the face is now pale, and covered with a cold sweat; the trismus is very violent; the eyeballs immoveable, and directed outwards; the sensibility and motility present the same disorders as before mentioned. The stools are involuntary; pulse 130. In the evening the coma gradually became more deep, and the child died at one o'clock after midnight.

Body examined fifteen hours after death.

External habit.—Body thin; a few phlyctenae on the scalp, produced by the blister; no rigidity of the body.

Skull.—The cranium is well formed: its parietes are rather thinned than developed; the dura mater is in its normal state; the longitudinal sinus encloses a dark coagulum of blood; the great cavity of the arachnoid membrane contains about an ounce of serum; under the layer of this membrane that covers the cerebral hemispheres, we observe a multitude of points of a yellow-whitish colour, some isolated, others confluent, and forming by their union small irregular plates, following the vascular trunks. On passing the pulp of the index finger along the surface of the arachnoid, we feel a slight resistance at the points corresponding with these little masses. On detaching the arachnoid and pia mater from

the brain, we can distinguish clearly these granulations, situate in this last membrane, and presenting a cartilaginous degree of consistency. They are more numerous at the right side than at the left, both on the convexity of the hemispheres and at the base; and are particularly confluent at the fissure of Sylvius on the right side. They are manifestly distinct, both in colour, form, and seat, from the glands of Pacchioni. A gelatino-albuminous substance exists at the base of the brain, near the decussation of the optic nerves: the lateral ventricles are distended by three or four ounces of turbid serum; the posterior cornu on the left side, and the pes hippocampi on the right side, present a ramollissement of a creamy appearance; the cortical substance of the hemispheres is slightly coloured, and the white substance pretty well injected; the cerebellum and pons varolii are healthy. The spinal marrow was not examined.

Neck and Chest.—The cervical ganglia, epiglottis, larynx, and trachea, do not present any alteration; the bronchial glands are transformed into tubercular masses; the serous membrane of the thorax is not adherent at any point between the lungs and thoracic wall; the right lung is studded with tubercles; some, like gray demitransparent granulations, others presenting a dull point in their centre; others, finally, of a yellowish white colour. We do not observe any cavity; the pulmonary parenchyma appears healthy in the intervals of the tubercles; the left lung also contains a great number of miliary tubercles, most of which lie immediately below the pleura. The pericardium, heart, and thoracic duct, are healthy.

Abdomen.—Small tubercles are disseminated throughout the peritoneal lining of the intestines, the liver, and the spleen; the parenchyma of this latter viscus is studded with them like the lungs. The pancreas and kidneys are free from all alteration. The mesenteric ganglia are not developed; only two or three are changed into tubercular matter. The gastro-intestinal mucous membrane is healthy.

In the first of the two cases just reported, the chronic stage, which so frequently characterizes tubercular meningitis, and its passage from the chronic to the acute form, are well marked. If we look to the cause under which scrofulous inflammation of the cerebral membranes was developed in the present case, we find nothing to which we can attribute it but the antecedent small-pox, though it is very doubtful how far this disease may influence the deposit of tubercular matter in any organ. The symptoms of the chronic stage, which lasted three months at least (and perhaps longer), were merely headache, and

that depression of the spirits and moral character which so often attends and points out the commencement of cerebral disease in children. In the present case, however, the diagnosis must have been difficult, for the child suffered at the same time under chronic inflammation of a similar nature in the abdominal cavity; hence the frequent pain in the abdomen, diarrhoea, &c., to which the headache and torpidity might reasonably have been referred, and to which they would certainly have been attributed by M. BROUSSAIS and his followers. The symptoms of chronic meningitis continued for a fortnight after the child's entrance into the hospital, when those of the acute stage suddenly declared themselves. What were they? Bilious vomiting, exasperation of the headache, falling of the pulse, and constipation, we insist strongly on these symptoms. Although, taken separately (abstraction made of the headache), they seem to have no connection with cerebral disease, yet, when united in the same subject, they are a certain index of inflammation of the meninges or the brain in cases where some prodrome has existed, as in the present case; and even when no premonitory phenomena has been observed, they afford the strongest presumption of the existence of meningitis. We have not yet had time to make an analysis of the cases we possess of meningo-cepbalitis, in order to determine the value of bilious vomiting as a symptom of the development of this disease; but we can affirm that it exists in a vast majority of cases, and is a most valuable sign. In the case we now speak of, it may be said, "The vomiting took place in a child affected with peritonitis, and was, therefore, of no value as a symptom of cerebral disease; inflammations of the abdominal cavity frequently produce vomiting in children, and may have been the cause in the case of Clemence Fournier." This reasoning is specious; we have often heard it employed, but its refutation does not require any great effort. The vomiting, if it existed alone, would certainly rather indicate abdominal disease than inflammation of the brain, but it must be considered in connection with other symptoms. Why did the pulse, at the same time, fall in frequency, and the diarrhoea give way to obstinate constipation, if the vomiting depended on an increase of the abdominal inflammation? It is impossible to connect these latter symp-

toms with peritonitis; they are, on the contrary, well-known phenomena of meningitis, and show that the vomiting must here, as in a vast number of other cases, be attributed to sympathy with the brain. It is unnecessary to follow this case through the other symptoms; the only one we would remark is the violent delirium with which the child was attacked on the night of the 6th. It is strange enough, but certainly true, that inflammation of the cerebral membranes seldom gives rise to severe delirium in children, and in a great many cases the intellectual faculties remain undisturbed during the whole course of the disease; in the present case the delirium was not attended with any febrile access; the skin was cool, and the pulse only 96.

The second case presents several traits of resemblance with the former one; here also we find a prodrome extending from the month of April to August (three months), and consisting in headache, with irregular accessions of fever. The passage from the chronic to the acute stage was also marked in the same manner, by bilious vomiting and exasperation of the headache. As to the other two symptoms, constipation and slowness of the pulse, it was impossible to determine whether they existed or not, as the child was not brought to the hospital until forty-eight hours after the acute attack, when she was in a state of coma. The other symptoms followed each other in rapid succession, without presenting anything worthy of notice; on the 6th the pulse mounted to 132. We merely mention this, because some systematic writers describe the last state of acute hydrocephalus as characterized by slow pulse; this is certainly an error. In a great majority of cases the pulse rises, towards the end of this disease, to 120, 130, 140, or even 150; it is always above 100; we would also direct attention to the absence of contraction of the limbs, although the fornix, and a portion of the lateral ventricles, were remarkably softened. Meningo-cephalitis rarely is fatal in so short a time as in the case now under consideration. The disease commenced on the 4th, and the child died in a state of coma at midnight on the 6th. In most cases the disease lasts from seven, eight, or ten, to twenty-one days. M. GUERSENT tells us that he has only observed a single case where it exceeded thirty days.

P. H. GREEN.

ON

FRACTURES OF THE PATELLA.

WITH PROPOSALS FOR A

NEW PLAN OF TREATMENT.

To the Editor of THE LANCET.

SIR,—I send the subjoined observations for insertion in your journal, if the proposal by which they are accompanied be worthy of attention.

Fractures of the patella must be considered as rather serious accidents, when we reflect on the rarity of their osseous union. From the retraction of the upper fragment of the bone, in transverse fractures, by the powerful muscles connected with it, and from the difficulty of keeping the broken surfaces in steady apposition by the ordinary means employed, the union is generally by ligament. The length of the uniting medium varies from half an inch to three or four inches, but, if it be more than half an inch, the patient can never walk securely.

Although such fractures are generally united by ligaments, yet the possibility of osseous union is now placed beyond doubt, by the number of instances recorded, and, it is owing to the inadequate means of treatment that osseous union is not more frequently effected. It is highly probable that, if we could scrupulously fulfil the indications of cure by proper modes of treatment, there is no fracture which, in ordinary circumstances, would not unite by bone, not excepting even fractures of the neck of the femur within the capsule. Deficient vascularity, I suspect, is not the true *rationale* of non-union in such cases. There are still some who seem to think that the organization of the patella is different from that of all the other parts of the osseous system, and that therefore, when broken, it must unite as regularly by ligament, as do the other bones by bony matter. It would be somewhat strange were the result of their practice in any one case to belie their theory.

Sir C. Bell is of opinion that the cause of the fracture exercises a material influence on its union. "In the common case," he says, "of fracture of the patella by the sudden action of the quadriceps extensor, the pieces are separated without that degree of violence which is necessary to produce reunion by bone. But, when the patella is broken by a blow or a kick, there is not only less retraction, but the injury, the bloody effusion, the tumefaction, and the rigidity of the parts, resemble that which attends the fracture of any other bone, and the fragments unite by bone." If he had merely said that, in fractures from direct violence, there is less retraction than in those

from muscular contraction, and that the former more frequently unite by bone than the latter, he would have been more correct. It is not from the greater violence which the bone sustains in fractures from blows, but from the capsule to which it is attached being less torn than when the fractures result from muscular contraction, that it more frequently unites by bone.

The chief points to be attended to in the treatment of fractures of the patella, as in all other fractures, are, 1st, To keep the fractured surfaces in apposition, and, 2ndly, To prevent motion between them. The means generally employed, I am inclined to think, are not adequate to fulfil these indications. The great objection that may be urged against them is, the undue degree of pressure which they exercise, either on the whole circumference of the limb, in the vicinity of the fracture, and thereby impeding the circulation below, or, by being confined to a point endangering the superintention of sloughing. The latter circumstance is a strong objection to Mr. Moggidge's ingeniously contrived apparatus. Mr. Moggidge, however, by this apparatus, obviated an objection which applies to all the other plans of treatment, viz., the circular compression, and consequent obstruction to the circulation in the limb.

In Sir Astley Cooper's plan (which is the one now generally employed), a belt is buckled round the thigh, immediately above the patella, and from each side of it a narrow strap passes down over the sole of the foot; but when this apparatus is put on lightly, which it must be when there is much retraction, it causes great swelling of the limb, and much uneasiness to the patient. Mr. Anesbury has improved on this plan, but his apparatus is so complex and expensive, as to preclude its use in the ordinary cases occurring in private practice.

The plan which I now propose is both simple and easily applied. It consists of a wooden splint, reaching about seven inches above and below the knee joint, and from four to five inches in breadth. To the lower part of it is attached, transversely, a narrow piece of wood, extending about two inches beyond either side of it, giving it the appearance of a cross. This transverse piece should be so placed, that its upper edge, when the splint is applied, will be opposite the spine or tubercle of the tibia. The limb being bandaged from the toes up to the middle of the thigh, the splint, padded with tow or cotton, is applied posteriorly, and fixed by several turns of a roller. The fractured surfaces are then approximated, and another bandage, two inches broad, is passed two or three times round the thigh, above knee, and then carried obliquely above the upper fragment of the patella, and downwards, underneath one of the transverse processes of the splint. It is then brought round it, and carried

upwards in the same direction, and made to turn round the thigh, at the point from which it started. The above manipulation is performed round the other transverse process, and repeated on each side successively, until the bandage, which ought to be several yards long, is expended. The position of the limb and trunk is then attended to, as in the other modes of treatment.

In applying the splint, we must take care (as already stated) to have the upper edge of the transverse piece of it placed opposite the spine of the tibia; otherwise the bandage which is last applied, is apt to slip over the patella. If we attend to this point, however, we can produce considerable traction downwards, and keep the fractured surfaces approximated, without danger of the bandage slipping, and with very little uneasiness to the patient.

I have had but one opportunity, as yet, of trying this method; but, from its success in that case, I feel warranted in recommending it to the notice of the profession. I am, Sir, your obedient servant,

K.

London, February 1, 1836.

APPLICATIONS AND EXAMINATIONS FOR A MEDICAL DEGREE,

AT EDINBURGH, ST. ANDREW'S, AND
GLASGOW.

To the Editor of THE LANCET.

SIR,—I am induced, more particularly by the statements in your last two numbers relative to the conduct of the Examiners of Apothecaries' Hall on a late occasion, to enter into the following personal details, for which, however, an apology to the public may be necessary.

Some years ago I offered myself as a candidate for the "Summi in Medicinâ Honores," as their dispensers call them, of the University of Edinburgh. Before any examination was begun, it was objected that my Paris certificate was insufficient for its object, viz. to count as *one* year out of the four required for the course of study. Now as the certificates, if I remember rightly, are sent in some months (*certainly some weeks*) previous to the day of examination, it is the business of the professors to see that they are sufficient, or to return them, and acquaint the student or candidate with that fact. This, however, was not done in my case; but, I presume, considering the omission to be their own (for I was not aware that I had not studied long enough), the Examiners probably were desirous at least of *appearing* to "make up for it," and accordingly I was admitted to examination.

The examiners were, Professors Alison, Graham, Monro, Duncan jun., Home, and Hope; and if I may be allowed to express an opinion of their *merits*, I may state that I have placed them pretty nearly in the order in which they should stand. After about two hours' examination, and ten minutes' deliberation among themselves, Dr. Alison presented to me my certificates, stating that the Examiners were not satisfied with them, and, consequently, that he should either recommend me to study for another month or two, or (what would be better) come up for examination in the following year. As I had reason to believe that the shortness of time occupied in my studies, and the circumstance that I had shown some disrespect, though perfectly unintentional,* towards one or two of the examiners, operated in some degree in producing this decision, I resolved to appeal to another tribunal; and, accordingly, I was soon on my way to St. Andrew's,—St. Andrew's! not, as formerly, the mercenary St. Andrew's, but St. Andrew's the *reformed*,—the St. Andrew's which then professed to examine into the *moral* character of the candidates, and to require from him some knowledge of the Greek. Alas! "*Dum loquimur, fugerit invida ætas*,"—everything changes in this world; and so sudden a change from the basest kind of prostitution to consummate virtue, would lead us to believe that miracles have not ceased.

But respecting the reasons which influenced the Edinburgh professors in recommending to me a second examination, more remains to be said. Dr. Hope, as is customary, I believe, wrote to ask me if the thesis which I had sent in, was intended for publication. I replied, no, not in Latin, but in an extended English form. Dr. Hope, as well as Dr. Duncan, and, probably, all the professors, were aware that I had long been engaged in making some inquiries into the blood; and I have little doubt that the intention which I expressed not to publish the Latin, but to extend the thesis, and publish it in English, might be considered as presumptuous in a student who had not yet passed an examination.

While coinciding with Gibbon in the opinion that an author is generally the best judge of the merits and defects of his own work, I also consider that a man is generally the best judge of his own qualifications and conduct in the case in question. Why, then, is his opinion of himself or his book

so seldom esteemed by the public? Not because he may judge incorrectly, but because he has not candour enough to acknowledge the defects. This may be the case with myself.

But did I answer all the questions put to me at the examination? Certainly not. Replies to some of them seemed as impossible as an answer to the question put to a student by the Society of Apothecaries,* viz., "How many *protoxides* of mercury are there?" I answered, I think, nearly two-thirds of them, but to give my adversaries fair play, let me allow that I answered only one-half. But when it was found that I did not intend to publish my thesis in Latin, it was not even examined, as I have good reason to know. I had *written* this Latin document myself. It was merely *corrected* by a master previous to being placed in the hands of the professors. I naturally enough, therefore, depended greatly on this "for passing;" for the corrections being made not in sentences, but in individual words, I could pretty fairly consider myself in the light of its author, in language as well as in matter. It extended to fifty pages; but this labour went for nothing, though, as I subsequently found that the thesis *always* weighs as nought, I must not here censure the examiners. However, as it had not been twice written, and the corrections were occasionally visible, this circumstance also may have been considered disrespectful, though quite unintentional on my part.†

Knowing that I had studied the profession most attentively, both by reading and by practice, for many years, I did not go for *six months* (as the custom was) into a grinder's shop, to have my mind "filed," as Shakspeare calls it, to the usual shape. I contented myself with six lessons on the general plan of proceeding, and found those too many.

I went to *St. Andrew's* next, because rather more classical knowledge seemed to be required there, under their new regulations, than either at Edinburgh or Glasgow. Besides, no further attendance on lectures was necessary before admission to examination. *Lectures* on the theory of physic, and on speculative physiology, are not near so well calculated as reading and comparing different authors, to increase our knowledge of medicine. Where lectures are illustrated by experiments, the case is different.

Professor Briggs, after examining my

* LANCET, Jan. 16th.

† Some of the questions of Drs. Home and Monro were so extraordinary, that they caused a little levity on my part; and some of those of Duncan and Hope were so supposititious, that they produced somewhat sharp retorts. Moreover, I had before thoughtlessly told Professor Turner that I should try Glasgow if I failed at Edinburgh. This was not very complimentary to his *intimate friend*, Dr. Alison, who probably, as well as all the Edinburgh Examiners, was informed of it.

† I may add here that I only took out *one* ticket from each Examiner; but I believe most students take out two, though this may not have influenced them. Again, though in the Latin questions I was not perhaps so quick or perfect as I should have been, yet I gave the English of Latin put to me which I had never seen before, without hesitation. Many candidates have passed at Edinburgh with much less knowledge of Latin, and, as I think, with less knowledge of physic generally.

certificates, was, I think, at first inclined to admit me to examination. But when in reply to his inquiry, Why, since I had studied at Edinburgh, I did not graduate there? I answered, "that having been once rejected, I intended to graduate elsewhere," the case was altered. Observing (as I conceived) this alteration in his sentiments, I did not press the matter; but at once departed elsewhere.

At first sight this hesitation of the Professor may seem to be confirmatory of an alteration in the University, as regards pecuniary considerations, the expense of the diploma being £35. But he had to support the new character of the institution, and I beg therefore to express my regard for his conduct. If I had passed at St. Andrew's after being unsuccessful at Edinburgh, he might have been afraid that the public would have said that he had sold me the degree; particularly as *morality** had only just begun to exert an influence at St. Andrew's. It was of course necessary to its reputation, that at least the first few years of its new life should be passed in a state of watchfulness. But not even then do regenerated characters always recover station in the public mind. Poor St. Andrew's! I fear the £35 were wholly lost to thee in any shape, for centuries may elapse ere the blot upon thy name can be effaced.

I called upon Professor Jeffray at Glasgow, wishing to pass my examination there before the summer had expired, but he told me that I was then *too late*, as it was necessary to take out *two Professors' tickets* before I could be examined. He, too, asked me why I did not graduate at Edinburgh, so that this well-known anatomist, who was one of my examiners at Glasgow, indifferent to the opinion of the Edinburgh professors, dared to admit a student to examination, and to pass him, whom the latter had thought fit to reject, for I was successful at Glasgow, and without any "grinding." As my rejection at Edinburgh was known to Professor Jeffray, it was probably also known to Professor Thomson, the other examiner. I therefore consider the degree I hold the more creditable to me, since the previous rejection could not have operated with the Glasgow professors at all in my favour.

I then went to Edinburgh and finished my book, which was already partly printed, and advertised it in the *Scotsman*, as written by "H. Prater, M.D., of the University of Glasgow." Obligated as I am to the Glasgow professors for their degree, still on that book,*—which, notwithstanding its bad arrangement and inequalities, has been regarded as one of the most profound and original works on the subject since the time of Hunter,—do I rest my chief claim for consideration as a physician or a physi-

ologist. The *Revue Médicale* of Paris has done me the honour to express, in their number for June last, a high opinion of its merits, and with all its defects, and these I hope another edition will allow me to correct, I cannot but cherish a belief that, sooner or later, it will come to be considered a standard work on the subject.

And now that medical reform is under discussion, I would beg to recommend to those who are in power, a court of appeal, in London, for students who may be dealt unjustly by at medical examinations. Think of the College of Physicians rejecting Armstrong and Mason Good! perhaps for some petty questions which those distinguished men would have lost time in honouring with a moment's attention. But public examinations, as THE LANCET has suggested, would be best and safest of all. Medicine is so vague a term, and some examiners are so fond of showing their powers of *crab*-examining, or their "extensive knowledge," (as was the late Dr. Duncan, particularly,) that when unchecked by public observation they may occasionally encroach even on the province of such an examination as would be given to apprentices by tea-dealers, or oilmen, or nursery gardeners, or God knows what other tradesmen, and call the examination one on "materia medica and the practice of physic!" In the classics and the exact sciences, there is no room for these excursions. It cannot be too often repeated that a check of some kind is required on medical examiners. What reason have we to consider such men as above the influence of personal prejudices, or social considerations?

I conclude by expressing my admiration of the noble stand which "the rejected candidate" has made against the "Pot-carriers." Perhaps his course was better than mine. I have the honour to be, Sir, your very obedient humble servant,

H. PRATER.

12, Dalby Terrace, Jan. 25, 1836.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Feb. 6, 1836.

MR. RICHARD QUAIN in the Chair.

DR. JOHNSON said he had this week seen a most interesting case, which at the same time had puzzled him more than any he had ever before seen. The subject of the case, who had led an active public life, was the only surviving sister of the late Mrs. Siddons, and was now in her 76th year. Two years ago, this lady consulted him (Dr. J.) for a very severe and obstinate pain at the back part of the head, which had existed for upwards of twenty years. She was then

* Prater on the Blood. Highley, Fleet Street.

a fine-looking active woman, full of spirits, and had invited the doctor to join a large dinner party, which his professional avocations prevented, and from that time until last Monday he had lost sight of her. Time and suffering had now wrought a great change in her person, which was reduced almost to the bulk of a skeleton. Her features were shrivelled, and indicative of great distress. Three months back a great difficulty of speaking came on, followed, in the course of a few weeks, by difficulty of swallowing, both functions gradually decreasing in power up to the last three months, when she became totally incapable of articulating and swallowing, and was, when he (Dr. J.) saw her for the first time during the present consultation, dying of inanition. The tongue presented a shrivelled condition, and was incapable of motion; in its centre were several small knotty prominences. Hunger and thirst, phenomena of considerable interest, were absent. Most of the other functions of the body were apparently healthy, the secretion from the kidneys and alimentary canal being necessarily scanty. The intellect was perfect, written answers being returned to inquiries, except to her attendant, who understood what she attempted to utter by the movements of the lips. He (Dr. J.) conceived that there was paralysis of the nerves which impart to the tongue the power of motion, and those which produce articulation, the eighth and ninth pair, these having their origin from that region of the head which had so long been the seat of suffering. The remedial means adopted at present had been first to support the system by nutritious liniments, adding to the first, fifteen drops of laudanum, which succeeded in producing some sleep. On the second day, two lavements were administered, and on the third (Wednesday) a small quantity of broth, with considerable difficulty, was passed down into the stomach, which produced, as that organ was greatly contracted, some uneasiness, from the distention that followed. This plan of treatment, since Monday, has been productive of some benefit, and today (Saturday) slight motion was perceptible in the tongue. The lady, although advanced in years, was anxious for life. Since the administration of the broth, a tenderness of the abdomen had supervened, which had been combated by sinapisms. An exceeding copious motion also had come away. Not a little curious to remark, after the first six or seven ounces of broth were passed down, a vomiting of pure bile succeeded, without its containing a single drop of the broth, showing the remarkable power of the system, when only functionally and not organically deranged, to retain completely that which was appropriate for the support of the body, while it rejected that which was offensive.

Dr. ADDISON related a case, not very much in point, and remarkable only, though not uncommon, for the following particulars:—A young woman, twenty-two years of age, was received into *Guy's Hospital*, a perfect skeleton, apparently labouring under irremediable organic disease of the abdomen, with an imperfect state of the uterine organs. A judicious administration and perseverance in the use of aperients, brought away, one after the other, stools much larger, collectively than it was imagined the contracted state of the whole alimentary canal would have allowed it to contain. Eventually her health was perfectly restored, and she grew fat, and became one of the sisters in the institution. She had lately had a relapse, attributable to her indulgence in the good things of this world, which are plentiful at *Guy's*.

HAHNEMANISM.

Dr. STEWART was now called on to furnish his paper on the operation of minute doses of medicine. After some judicious introductory remarks, the Doctor begged to be understood as condemning, without respect of persons, *in toto*, the blue pill plan, the Morison-pill plan, the bread-pill plan, and all other indiscriminate plans, which pretended to reduce to uniformity what was in its nature infinitely varied and complicated. A due variety of remedial measures, administered under the personal direction of medical men, was the distinguishing mark of rational practice. But even after allowing a choice of means, there have been very opposite ends proposed in their employment. The contra-stimulant and homœopathic systems stood remarkably contrasted, not only as to the doses of medicines, but also from there being in the former very little regard paid to the symptoms produced by the remedies, and in the latter the affection of a great deal more attention than usual. Homœopathy comprehended not only the imitation of disease in the administration of remedies, but the diminution of the dose. With regard to this ingenious supplanting of disease, as recommended by Hahneman, he (Dr. S.) thought that there existed a delusion, the copy existing only in the mind's eye, while the reality was going on, uninfluenced by the phantom of physic which was to frighten it away. Looking at the liberal allowance of time which was made, often from a week to a month, between the doses, and calculating the comparative and relative agency of all the elements of a homœopathic case, he (Dr. S.) concluded that it was not the small dose of medicine, but rather the large dose of time, which worked the alleged cures. As to the principle of homœopathy, the plan of treating *similia similibus*, there was nothing in it that was new. Diarrhoea had

frequently been cured with purgatives, gonorrhoea with irritants, and sailors were even said to cure old gleet by contracting a fresh clap. With regard to the question, whether the doctrine taught by Hahnemann was quackery or not, the answer was to be found in the reply to the inquiry, Is any part of the system concealed, or is it laid before the profession in a manly way, and open to inquiry and experiments? Medical societies afforded good tests of such questions. They served the purpose which Frederick of Prussia employed with the philosophers whom he invited to his court, saying that he knew how to squeeze the orange and throw away the pulp when he got them there. Medical societies were capital squeezers, though they did not always obtain much juice. (*Applause.*)

The drift of the paper was for the most part lost sight of in the speeches which followed, and as the subject is postponed for future discussion, we leave to another occasion further remarks. The evening passed off merrily, if not instructively. At least the cloud of silence which has hung over the Society for the last two nights was dissipated to-night.

ST. GEORGE'S HOSPITAL.

THE NEW CODE OF LAWS.

LAST year we devoted an occasional page to reports of meetings of the governors of this hospital, to form a new code of laws for its government, and did some good by exposing to public view the proceedings of the medical junta who had obtained sufficient interest among the subscribers to commit all kinds of corrupt and illiberal acts, in wielding the patronage and managing the affairs of the institution. The final committal of the new laws was, at a certain stage of their consideration, adjourned until January 1836, and that time having arrived, their discussion has been renewed, and we are now prepared to give an abstract of the fresh debates on their revision, and the results.

The adjourned Special Court met on Monday, January 11th. Mr. HOLLAND in the Chair. The first matter discussed worth mention was the motion Dr. WILSON intrusted to the care of Dr. CHAMBERS, for expunging those words from law 11, which declared that medical governors should not inspect the hospital "*for the purpose of obtaining medical and surgical instruction, under colour of such inspection.*" This law was originally intended by Sir B. Brodie's worthy party, to keep every medical visitor out of the hospital, unless he had paid to the medical officers an enormous fee—a subscrip-

tion for the benefit of the patients, giving no privilege in the wards.* This greedy and disgusting law was carried on the 2nd of June, 1835,* by a majority of 30 to 29, in a full meeting of governors. But the exposure which attended its adoption enabled shame to get the better of avarice, and at this adjourned meeting it was unanimously expunged, Dr. CHAMBERS on this occasion merely intimating to the independent majority of 36, that it was not now either his or Sir BENJAMIN'S wish to place such a law on the books. The result was of course very gratifying to the few governors who stood forward to advocate the enlightened side of medical polity. Practitioners may now visit the wards of the hospital, both for the purpose of scrutinizing the practice of the officers, and with the object of seeing such practice as its walls afford. Dr. WILSON, in his remarks on the subject, took the opportunity of exposing the majority who voted on the former occasion, and of pointing out the good effects of perseverance on the part of a minority, and Dr. WOOD took care to obtain an explicit *proviso* that licentiates in medicine and surgery should have "access to the wards of the hospital, at proper times, on the introduction of a Governor."

Attention was then called to a substitute for law 13, which related to the "expulsion" of governors at the caprice of the Brodie party,—or, as the excuse ran, *for any conduct, in connection with the hospital, or any notorious public scandal, calculated to bring discredit upon the hospital.*—on the bricks and mortar, we suppose, for how anybody but themselves could bring discredit either on the patients or the medical officers, we cannot pretend to guess. Much angry discussion ensued, and the "expulsion" law—wise and provident measure—was carried. Mr. Fuller, the lawyer, in a business-like way, contended that the governors ought to submit to the adoption of this law, because it was copied verbatim from the law-book of the Law Association. Dr. WILSON could not see the justness of the precedent, and opposed it. For our parts, we think it would be as correct to order wigs and gowns all round for the medical officers, because the barristers wear them in the law wards at Westminster. Mr. HOWSHIP voted for the clause because Dr. Wilson opposed it. Mr. TRIMMER, in an able speech against it, asked Mr. Bagshaw, the lawyer, whether an action at law would not justly lie against the nine individuals who might "expel" a governor, and publish their libellous reasons for the proceeding. As Mr. Trimmer offered no fee for the opinion, the lawyer declined answering, and it was generally agreed that the laws of no other hospital contained a similar

* Lancet, page 333.

clause. Mr. JAMES LANE, Dr. WOOD, and Mr. ANCELL, also spoke against the law; RODERICK MACLEOD and Mr. BAGSHAW in its favour. The minority, however, Mr. TRIMMER at their head, succeeded in getting appended to the clause the following declaration:—*that no question relating to the expulsion of any governor shall be considered, or discussed, or acted upon, at any weekly board at which there shall not be present twelve governors, nor any question relating to the expulsion of a governor at any weekly board be carried by a majority of less than two thirds of the governors present.*"

Friday, January 15th.—Mr. HOLLAND in the chair. Several amendments of no public import having been agreed to,

Mr. JAMES LANE moved as a law that, "No governor or governors shall circulate any notice or statement bearing date from the hospital, relative to any election, or tending in any way to influence the votes of governors at any election, unless such notice or statement shall have been previously sanctioned by the weekly board." He said that at a late election of an assistant surgeon, six of the medical officers dated a circular letter to the Governors from the hospital, to the unjust prejudice of one of the candidates, and he wished to guard against the recurrence of such a proceeding, which tended to deprive gentlemen who looked forward to the offices of the hospital as a reward of their industry and professional attainments, of a fair chance of competition.

RODERICK MACLEOD acknowledged that the dating of the circular from "St. George's Hospital" was decidedly wrong, and attributed the circumstance to an "oversight."

Captain BAGSHAW observed that in respectable societies the office bearers scrupulously avoided any interference in the election of coadjutors; he wished as much delicacy was exhibited at St. George's. At present the successors of medical officers were only looked for in the pupils of particular persons, without regard to their capability. The circular in question was evidently an attempt to influence the governing body at the eleventh hour, when reply on the part of a candidate was impossible.

Dr. SKYMOUR on the other hand asserted that the governors of all medical institutions invariably referred to the medical officers the candidates for vacancies, and it was in fact the duty of the medical officers to interfere, in order to guide the votes of the governors.

Mr. ANCELL referred to the elections at the Western Dispensary in proof of the incorrectness of the statements of the last speaker. In that institution the medical officers made it their business to abstain from all interference in the elections, and he appealed to Sir B. Brodie, who is connected with that institution, to say whether

the governors had failed in electing a qualified individual. Altogether, the jealousies and private interests of the medical officers wholly disqualified them from electing their coadjutors, who stood a chance of rejection, exactly in proportion to the independence of their character, at least at St. George's hospital.

Dr. WILSON showed that the existence of two editions of the circular palpably exposed the character of the "oversight" suggested by Dr. Macleod. He also reflected on the circumstance of a copy of the circular being immediately sent for insertion to what he described as "a disreputable and contemptible periodical, with which Dr. Macleod was intimately connected, if not the avowed editor."

Ultimately the law was passed.

Monday, January 18th.

The meeting of to-day was, as is usual, opened with a prayer for charity, Mr. HOLLAND in the chair. The story of the grocer and his apprentice, who sanded the sugar and watered the molasses before devotion, was thus forcibly brought to mind. The room was said to be two-thirds packed with Sir BENJAMIN'S disciplined men.

Mr. ELKINS' motion stood first—"That lists be taken of the majority and minority of such governors as vote on any matter decided at any weekly board, provided three governors present shall require it, and that such lists shall be entered by the Secretary as a part of the minutes." In an able speech Mr. E. pointed out the necessity for keeping a faithful record of the proceedings of the board, and on the general advantage of registering the votes on matters of importance, a proceeding to which conscientious voters could not object.

Mr. MORLEY seconded the motion. He thought the law would prove a salutary check on the votes of those who decided on questions before understanding them, as did many governors at present, thus often sacrificing the interests of the institution to party feeling.

Mr. JAMES LANE felt convinced that such a law would have prevented the extraordinary proceeding of the last meeting, when a motion which had undergone a thorough discussion, and was supported by the speeches of four of the medical officers, and was carried by 36 to 29, was rescinded, at the dicta of Dr. Chambers and Sir B. Brodie, who were not present. "Surely," Mr. L. said, "those 36 gentlemen could not, if their names had been recorded, have submitted to this degradation as voters." He also advocated it upon personal grounds. It had been stated in the board-room and in the wards of the hospital, by one of the medical officers, that in consequence of his (Mr. J. Lane's) factious opposition to these

laws, his brother the surgeon should never be an officer of the hospital. He (Mr. Lane) was anxious to have his vote recorded upon every occasion, for he never did vote factiously.

Mr. FULLER (the lawyer) opposed the motion, because no institution in the world afforded a precedent for it.

Dr. WILSON thought that publicity should be given to all the proceedings of the board.

A GOVERNOR (not usually an attendant) said he had heard so many arguments for the motion, and only one speech against it, (the world being too large to be searched for precedents, and arguments being wanting on the contra side,) that he should vote for the motion.

Mr. ELKINS replied, and adduced several precedents, among others, the meeting of the Middlesex magistrates, on Mr. Rotch's business, when the votes were recorded.

The motion, however, was negatived by a large majority.

Dr. WILSON next proposed that the physicians and surgeons "should meet in committee" at stated intervals, "to consider all matters relating to their office, and report proceedings to the Weekly Board." He considered the enactment essential to the proper conducting of the hospital affairs. A year and a half ago the medical officers were deputed to report on a proper site &c. for the erection of baths in the hospital, yet no meetings to consider the matter had ever taken place. The museum, also, was, by the new laws, placed under the care of the medical officers. The questions pending as to the medical schools of the metropolis, rendered it also imperatively necessary for the medical officers to meet, from time to time, in committee, to protect their common interests. Desirous, too, as he was, of avoiding personal matters, he could not omit alluding to the indecacy of issuing a prospectus, headed "St. George's Hospital," with his (Dr. W.'s) name attached to it, without consulting him, and in defiance of his written protest to the contrary.

Dr. SEYMOUR said he should oppose all such propositions. It would be attended with the greatest inconvenience to himself, and it was highly derogatory to the character of a high-minded physician to be compelled to adopt this specific course.

Mr. NUSSEY, one of the visiting apothecaries, considered the governors would have reason to be offended at such meetings.

Dr. CHAMBERS also opposed the law. At such meetings nothing but angry discussions could ensue. As matters now stood, disputes could be got rid of by a word, and if the governors enacted the clause, he must decline attending the Committee.

Mr. STONE was in favour of the law. Had it before been adopted, the whole of the dissensions, and their consequent evils, which

he had now to deplore, would have been averted.

RODERICK MACLEOD opposed the law because it would afford opportunities for gentlemen to "have a fling at one another."

Mr. ANCELL considered the arguments against the law to be entirely personal, and such as the Court could not properly entertain. The Court had recognised the medical officers as a body, and delegated to them certain powers which it was incumbent on the Court to take care should be properly exercised. He regretted to hear some of the medical officers refusing to act with others because differences of opinion existed amongst them, and he thought the Court was in error in recognising dissensions in the medical staff, which it certainly would do in opposing the present law.

Dr. WILSON stated that, after what had fallen from his senior colleague (Dr. Chambers), he had not a doubt which way the matter would end. In answer to Mr. Nussey he replied, that meetings of the medical officers do take place,—meetings to call up the servants and to censure them,—without any reference to the weekly board of management. For instance; upon the recent election of a chaplain, the porter was called before the major section of medical officers, and censured because he was suspected of being favourable to the candidate whom that section did not support. It was for the purpose of regulating the meetings of the medical officers that he proposed this law, and, moreover, to ensure the first step towards conciliation in the management of the hospital affairs.

The law was rejected by a large majority, and the meeting adjourned to the 22nd.

Friday, Jan. 22nd.—Mr. HOLLAND in the chair.

Sir CULLING SMITH moved that "In the absence of the two senior surgeons, their patients shall continue to be attended by the present senior assistant surgeon." In a mild, gentlemanly, and conciliatory address, the hon. Baronet besought the medical officers to return to the arrangement which subsisted prior to the election of a second assistant surgeon, and to remove the impression that it was intended to humiliate an officer who had served the hospital with zeal and ability for upwards of six years. The present arrangement, also, was detrimental to the best interests of the institution.

Mr. JAMES LANE entertained the same views, not doubting that the law would be in accordance with those of Sir B. BROSIE, who pledged his word to Mr. Walker that the election of a second assistant surgeon should not in any way prejudice him, or disturb the existing arrangements.

Sir B. BROSIE made a statement respecting his own conduct, in which he alluded to

some paragraphs in the newspapers as a justification of the proceedings of himself and his colleagues towards Mr. Walker. It was true that he had pledged his word of honour to the effect stated by Mr. Lane, and he should now be glad to have Mr. Walker's efficient services as his assistant, but his colleagues, without consulting him, had entered into a different arrangement. Sir Benjamin was twice called to order in his personal statement, but the chairman ruled that it formed a proper subject for discussion.

Mr. KEATE, Mr. BABINGTON, and Dr. SEYMOUR, followed, the latter saying that the present arrangement was so perfectly symmetrical that he should certainly oppose its disturbance.

Mr. CUTLER considered that the governors would be guilty of great injustice to him, if they deprived him of a privilege which he had enjoyed for twelve months.

Sir CULLING SMITH, in reply, observed that he had heard nothing which altered his view of the case. If it could really be shown that the symmetry of the arrangements would be destroyed, he should relinquish his proposal, but he had the authority of Sir B. Brodie himself that it would not. Bearing in mind that Sir Benjamin wished to have Mr. Walker's services, and that Mr. Walker was anxious to be Sir Benjamin's assistant, he could not conceive why the other surgeons should oppose an arrangement to which the parties most interested consented.

Sir Culling's motion was then put to the vote, and, of course, negatived.

Mr. JONES moved, "That the income of the present apothecary should not be reduced beyond his average salary for the last ten years." Towards the conclusion Mr. Jones remarked that on inquiring of a governor why Mr. Hutchins, the present apothecary, was alone made to suffer in his income, he received for a reply, not that he was an unworthy servant, for the contrary was acknowledged on all hands to be the case, but that he was "on the wrong side." Having no personal knowledge of Mr. H., but being acquainted with gentlemen on the strong side in that room, he had been afraid that this was the true cause; but Dr. Seymour had entirely disclaimed its correctness. He now, therefore, had no doubt that those who had the power to avert oppression would cordially support his motion.

Mr. JONES, however, was grievously in error. The usual minority alone supported his motion, which was of course negatived.

Our reporter then goes on to state that on the question of adjournment being put,

Dr. CHAMBERS rushed to the table, foaming and furious, and thus addressed the presiding officer:—Sir, I have a complaint to make of neglect of duty. I have been into the wards, Sir, and am told by a person on

whose authority I can rely, that the patients have not been seen for a week past. Sir, my mind is perturbed, my spirits are oppressed, my feelings are assailed, and the business of the hospital is obstructed. The time of the medical officers is taken up in this Board-room by factious governors coming here to bring forward futile motions.

Dr. WILSON rose to order, but was overruled by the chairman.

Dr. CHAMBERS proceeded:—by Governors coming down here with factious motives, and bringing forward motions which they know cannot be carried,—when they know they will be beaten, two, three, four to one—four to one, and having no other desire than to take up the time of the medical officers in this Board-room, and causing the patients to be neglected. Having proceeded in the same strain for some time longer, actually livid in countenance, and foaming at the mouth, he turned from the table.

Mr. J. LANE.—Sir, as you have thought proper to rule that Dr. Chambers was perfectly in order in imputing factious motives to governors, I, as one of those who have given notices of motion, trust you will call on Dr. Chambers to state whether he alluded to me.

Dr. CHAMBERS.—Sir, I have no explanation to give.

Mr. LANE.—Then, Sir, you had no right to make such accusations. (*Great uproar.*)

The CHAIRMAN said, as Dr. Chambers had made so grave a charge and had thus left it, of course he would retract the objectionable expressions.

Dr. CHAMBERS did so, saying that he meant nothing personal.

Mr. LANE then said, that the inconvenience arose solely from the medical officers having been allowed to occupy nearly the whole time of this meeting in criminations and recriminations. The charge of factious motives he wholly denied.

The CHAIRMAN here interfered and said he should not allow this matter to proceed any further, on which the meeting broke up in great confusion, and with many censures on the conduct of Dr. Chambers, and some on that of the chairman.

Monday, Jan. 25.

Prayers.—Mr. POWELL in the chair.

Mr. MORLEY wished to have some opinion as to the conduct of Dr. Chambers at the last meeting, but the chairman objected. Mr. M. then handed in a written paper on the subject, which was refused.

Mr. J. LANE moved the incorporation of two clauses of the Apothecary Laws. Feeling from what took place at the close of the last meeting that those governors who brought forward independent motions had not the protection of the chair, he had de-

terminated on not attending this meeting, but on reflecting that the conduct of one individual ought not to control his proceedings as a governor, he resolved to be present, though, with regard to his motion, he had no expectation it would be decided on its merits alone, and therefore he withdrew it for the present.

The CHAIRMAN begged Mr. Lane to proceed.

Mr. LANE did so, though with every doubt of a fair discussion. He then explained his views on the subject, but we are compelled to say that some deficiency in the notes before us prevents the arguments on the question from being sufficiently clear for publication. The tendency of the arrangement opposed by Mr. Lane seemed, according to the report, to sanction the entrance of pupils to the assistant apothecary, whose interest it would then be to attend to his pupils rather than to the regular business of the hospital.

Mr. BAGSHAW contended that the meeting had not power to concede what Mr. Lane desired.

Mr. BENSON (a barrister) differed from his learned friend, who he thought carried his special pleading and legal quibbling rather too far.

Captain Bagnold thought that the quibbling was not too paltry for the Old Bailey, but that they would be ashamed of it even at the pie poudre court at Bartholomew-fair.

After an hour and a half's speechifying it was decided that the meeting could amend the clauses opposed by Mr. Lane.

Mr. KEATE supported the views of Mr. LANE, and made a motion to that effect.

Mr. FULLER moved that the clauses do stand as they are, which was carried.

Dr. WILSON then withdrew his notice of motion. In consequence of the proceedings at the last meeting he could not consent to bring forward any motion, and he took that opportunity of informing the governors that he had seen all his patients three times during the last week.

Mr. BABINGTON took up Dr. Wilson's motion, and it was carried.

Captain BAGNOLD moved that when a patient was attended by the assistant surgeon, his name should be placed on the bed card, as well as that of the surgeon.

The surgeons objected; motion withdrawn.

Mr. J. LANE now felt convinced that he could not carry a motion that stood in his name, and he therefore withdrew it. All the others but one (which was passed) were also withdrawn, and the meetings terminated.

Our reporter adds,—"Upon the whole these reports exhibit an instructive lesson. They show how even a public institution may be rendered thoroughly subservient to the interests of a party. Such a result is not difficult of accomplishment in an esta-

lishment in which the government depends on the voices of individuals whose title to vote may be supplied from the purses of the party who profit by holding office in the institution." The principles on which laws for public hospitals should be founded, and which should alone be followed in the decision of questions of management, are wholly abandoned in the operation of such a system. Those principles are few and most simple. The first concerns the patients,—how *their* wants may be supplied. The second concerns the public,—how the science of medicine may be best served as a means of promoting the public health. That these objects are the very last which have been considered by the party of Sir BENJAMIN BRODIE in legislating for *St. George's Hospital*, is so plain, that words would be wasted in a farther exposition of the fact.

FOREIGN MEDICINE.

Gazette Médicale de Paris, January, 1836.

THE four numbers of this journal for the month of January, 1836, contain so few original articles, that the whole are comprised in the following communication:—

1. Memoir on the False Membranes of the Cerebral Arachnoid, founded on Observations collected at *Bicêtre*, by M. F. LELUT.

2. Memoir on Gangrene of the Lungs in Deranged Patients, by M. J. GUÉLAIN.

3. Clinical Reminiscences of *St. Louis*. Wounds of the Head, by J. F. MALGAIN, M.D.

FALSE MEMBRANES OF THE ARACHNOID.

The memoir of M. LELUT contains twelve observations of arachnitis in insane patients, accompanied by an exudation of false membrane. In all these cases the intellectual faculties were deranged in the most serious manner, and there was, in addition, some lesion of motility, consisting either in convulsions, agitation, or paralysis. The false membrane in all cases existed in the cavity of the arachnoid, like the false membrane in pleuritis or peritonitis; it was never found between the arachnoid and pia mater, although Dr. ABERCROMBIE and several other writers speak of false membranes interposed between these two membranes. Indeed, many authors fall into this error. How many times do we see a case described as inflammation of the arachnoid, while the patho-

logical change is described as altogether existing outside that membrane!

The false membrane, in almost all the cases examined by M. LELUT, was situate on the convexity of the hemispheres, occupying the anterior part particularly: the author explains their mode of formation in the following manner. When simple serum is effused into the cavity of the arachnoid, it gives rise to the formation of false serous membranes, similar to those observed in true acute arachnitis. When, on the contrary, blood is exhaled in such a manner as not to produce a fatal apoplexy, the serous and aqueous parts are absorbed, and nothing is left but the fibrine, which is ultimately converted into a new tissue.

The authors who have observed false membranes on the arachnoid in a chronic form, are agreed in thinking that it is generally impossible to diagnosticate this lesion. Its symptoms are commonly confounded with those of cerebral compression or irritation, so frequent in maniacal patients.

GANGRENE OF THE LUNGS IN THE INSANE.

The memoir of M. GUISLAIN also refers to a condition sometimes observed in insane persons. LAENNEC describes gangrene of the lung as a very rare disease; he saw it only six or eight times in the course of eighteen years' practice; M. GUISLAIN has had occasion to see this disease much more frequently, in the insane patients at the hospital of Gand. He considers it as depending on the following conditions, viz., 1st. An aberration of the moral power consisting in a disgust and horror of all food. 2nd. A deterioration of the blood, in consequence. 3rd. An alteration of the pulmonary tissue, as a final result.

The attention of the author was first drawn to this disease by the circumstance of excessively foul breath in a patient, who for a long time had refused every kind of aliment. On examining the body he found the lungs extensively sphacelated. This obstinate refusal of food exists in many patients affected with melancholy; in one-ninth of all the insane, according to the author, it is excessively difficult to overcome; they sometimes remain twenty, thirty, or sixty days without accepting any food, drinking nothing but some cold water, or fasting the

first days of the week and then eating on the rest.

M. GUISLAIN has made thirteen autopsies of deranged persons who thus died in a state of inanition: in nine of the thirteen he found the lungs gangrenous: in three cases the tissue of the lungs was of a darker colour than usual, and in one there was a simple congestion at the posterior part of the lungs. In the gangrene, one lung was always more affected than the other, and the lesion, which never implicated more than one-fifth of the lung, was more sensible at the summit than at the base. The patient never seemed to suffer any pain in the chest; he did not cough; the respiration was not difficult, nor was there any appearance of fever: the skin was cooler than natural, and the pulse rather retarded than accelerated.

In all the insane patients who have abstained for any time from eating, the author observed a special symptom, viz., a change in the colour of the skin, always more striking the longer the patient remained without eating. This consisted in a brick-red colour of the cheeks, passing by degrees to brown or purple. It probably depends on a change in the composition of the blood, produced by abstinence. Inflammation of the stomach or abdominal viscera was not observed in a single case; the stomach always presented itself with the most healthy appearance. This is the more curious, as the experiments and observations of HALLER, DUMAS, BROUSSAIS, MAGENDIE, and ADELON, show that in most cases of forced abstinence the stomach affords traces of inflammation or even of erosion. In the insane person who refuses food, we find nothing of this; we see no trace of pain. When restored to his faculties, he affirms that he never felt hunger; we remark no fever, no heat of skin, no acceleration in the pulse. In abstinence of a healthy individual the force sinks rapidly; in the insane, on the contrary, the force is sustained nearly to the last day. He comes into the hospital after having fasted for 20, 30, or 40 days. He walks about, takes ordinary exercise, and continues to live in a state of extreme emaciation, though not much debilitated, for months, or even years, swallowing from time to time a mouthful of broth, while another person subjected to the same privations would die in eight or ten days. Insane patients affected with this disgust for food not only seem to be indiffe-

rent to hunger, but the other senses appear equally modified. Thus they support the sensation of cold and heat with an astonishing indifference; a heated iron applied to the skin produces scarcely any sign of suffering; they are indifferent to the loudest noises; they regard the sun without blinking, and all the other senses are in a similar degree of stupor. The following case, which we quote from the memoir of M. GUISLAIN, shows that when the mental state has not made too great progress, we may hope to overcome the resistance of the patient, and even when the pulmonary lesion is very grave, an unexpected cure may take place:—

Case.—Marie de Leest, descended from a family in which several members were mad, was seized with a deep melancholy while in the establishment of the author. The patient was 28 years of age, of very delicate complexion, blue eyes, and light hair. Two months after her entrance she commenced to refuse all kinds of food; three days passed in perfect abstinence. Threats and entreaties were employed in vain. At length force was had recourse to, which succeeded twice; but the patient soon offered such violent resistance that the liquid was retained in the pharynx, and after some time rejected by the mouth. The introduction of a tube into the œsophagus was impossible. The same fruitless efforts to introduce a little food were repeated day after day; sometimes, perhaps, a few spoonfuls of broth were passed. The colour of the face now commenced to assume the pathognomonic character. The force declined gradually, and after two months spent in complete abstinence she commenced, without any previous cough or difficulty of respiration, to spit up fetid matter, at first rusty-coloured, and finally brown. At this time she did not eat a single morsel of food, as we were afraid to employ force lest suffocation should be produced. However, after remaining some time in this condition, she suddenly determined to eat, and in a few days the face recovered its former pale colour; the sanguineous fetid expectoration ceased by degrees, and the patient at length recovered a perfect state of health. She left the house in 1829, but came in again in 1831. This time also her disease was characterized by a refusal to eat, and by pulmonary disease, under which she sank. On opening the body, the left lung was found reduced to a dark and fetid mass.

Archives G n rales de M decine, September, October, November, December, 1835.

The press of other matter prevented us on a former occasion from noticing more than one or two articles contained in the last four numbers of the *Archives G n rales*. We now return

to the original papers contained in this excellent journal for the last *trimestre*. They are,

- 1st. Researches on some of the causes that hasten or retard the period of puberty; by M. MARC D'ESPI NE.
2. Conclusion of Researches on Dysentery. By M. THOMAS.
3. Researches on the Pulse, the Respiration, and the Temperature of the Body in Diseases, and on the Relations existing between these Phenomena. By M. A. DONNE, Chef de Clinique.
4. On the Physiological and Essential Effects of the Rarefaction and Compression of the Air on the Body or Limbs. By M. T. JUNOD.
5. M moir on Pericarditis. By M. HACHE, Interne.

THE PULSE, RESPIRATION, AND HEAT.

We present our readers with the paper by M. DONNE, on the relations which exist between the pulse, respiration, and animal heat, in different diseases.

The experiments which form the basis of this memoir, were conducted at the hospitals of *La Piti * and *La Charit *, with the object of determining how far the pulse, the respiration, and the heat of the body, are affected simultaneously or independently in several diseases. For a statement of the numbers ascertained during the great series of experiments made by M. DONNE, we must refer to his memoir. Our space will only permit us to notice some of the general results which have been obtained. The experiments were made on persons affected with pneumonia, pleuritis, phthisis, hypertrophy of the heart, hemoptysis, chlorosis, diabetes, puerperal fever, hemiplegia, hysteria, jaundice, &c.

The first question examined was, in what diseases do we find the pulse most frequent, and the animal heat most elevated? The following numbers, selected from amongst a great many experiments, answer this first question:—

	Pulse.	Temperature.	Respiration.
Hypertrophy of the heart	150	39½	34.
Puerperal fever	168	40	48.
Phthisis	140	39	62.
Typhus fever	136	40	50.

The above cases were those in which the pulse and heat had attained the highest degree of elevation; the latter was measured by the centigrade thermometer, thirty-six to thirty-seven degrees of which give the normal temperature of the human body. It may be seen, from the above table, that the acceleration of pulse was always accompanied by an elevation of temperature; the skin is most warm in those individuals in whom the pulse is quickest; this rule, however, cannot be generalized too extensively; it is not true in all diseases. Thus M. DONNE gives forty-two experiments made on patients affected with pulmonary tubercles; in twenty-six we do not find any relation between the temperature and pulse; in sixteen cases only, the animal heat fell or rose in proportion to the slowness or acceleration of the pulse. Again, in ten observations made on pleuritic patients, we cannot discover any relation between the state of the pulse and the degree of heat; on the contrary, in seven experiments made in pneumonia, the heat constantly rose with the pulse. The same relation was observed in twelve experiments on patients affected with hypertrophy; in eleven experiments on puerperal fever; in four experiments on jaundice; in six experiments on acute rheumatism; in five experiments on inflammatory fever; and, finally, in six experiments on typhus fever. In fourteen experiments made on females affected with chlorosis, the relation of the pulse and heat was by no means constant.

The above numbers confirm, in an exact manner, an opinion generally received amongst physiologists, although it never before was proved by direct experiments on a large scale—viz. that the animal heat often ascends or descends with the pulse. They also prove another point, which is contrary to the ideas generally received. They show that in some cases there is no *proportion* whatever between the number of pulsations and the degree of heat, although the relation of ascending and descending may still exist. Thus, in one case of typhus fever, the pulse being at ninety, the thermometer marked thirty-nine degrees; and in another where the pulse was up to 108 it marked 40°, the maximum of heat in the human body. M. DONNE, however, remarks, that typhus fever is the only disease in which he observed this great disproportion between the pulse

and heat. In the normal state of the body, we do not find this close connection between the pulse and animal heat; this is easily proved by experiments, which every one can perform on himself; we can make the pulse mount fifteen or twenty beats in the minute, without producing the least change in the temperature of the body. In cases of disease this is not the case; the heat is elevated with the quickness of the pulse; but here an interesting question, which has never been examined by physicians, presents itself. Does this relation between the pulse and heat exist more in one disease than in another? Is it influenced by the nature of the disease? Thus, for example, does it depend on the integrity of the organs of sanguification, of the nervous system, or of any other apparatus?

These questions are resolved by the tables given by M. DONNE. Thus, in tubercular affection of the lungs, and in pleurisy, the relation between the pulse and heat is more frequently absent than present. In chlorosis, again, we do not observe this relation; the latter disease, indeed, does not belong to the pulmonary organs, but sanguification may be regarded as imperfectly performed. In organic affections of the heart, such as hypertrophy, contraction of its valvular openings, &c, the relation is not constant, but it is more frequently present than absent. On the other hand, in puerperal fever, in hemiplegia, jaundice, inflammatory fever, ague, and peritonitis, the relation between the pulse and heat was almost constantly observed. In the theory of animal heat, such as it is generally admitted at the present day, after the researches of MM. DELONG and DESPRET, the augmentation of the animal heat may be attributed to the acceleration of the circulation. In this theory, nine-tenths of the heat in animal bodies is attributed to the combination of the carbon of the blood with the oxygen of the air, and hence the more quickly the blood passes through the lungs, the more carbonic acid will be formed, and the more the heat of the body is elevated. However, some strong objections may be made to this theory. In the first place, it is remarkable that one of the diseases in which the animal heat is most elevated, is precisely that in which sanguification is most imperfectly performed: thus, in pulmonary consumption, the heat of the body often rises to 38°, 39°, or 40°, even,

where one half or two-thirds of the lungs are indurated, and impermeable to air. Again, the experiments made in typhus fever, show that the animal heat depends on other sources than sanguification and assimilation; in that affection, certainly the pulse is not always much accelerated, nor the respiration very quick, yet we find the heat of the body mounting in one case to 39° , with a pulse of 93; in a second case, equally to 39° , while the pulse was at 108, and the respiration at 28.

M. DONNE proposes to follow up these interesting inquiries. We shall take care to communicate his observations as they appear.

PERICARDITIS. *

The memoir on pericarditis, by M. HACHE, is an excellent *resumé* of the present state of our knowledge on pericarditis, by an old interne of M. LOUIS. The conclusions to which he comes are based upon eight cases of pericarditis, observed with all the care peculiar to the pupils of M. LOUIS's school; of eight more cases, collected by M. LOUIS between 1830 and 1833; and, finally, on an examination of these original observations with those published very lately by Professor BOUILLAUD of *La Charité*. It is not our intention to go over details already sufficiently known to the profession, we shall therefore merely notice a few principal points in the memoir of M. HACHE.

The cases observed by our author may be distinguished into two kinds; one where the disease was simple; the other in which the pericarditis was accompanied by various complications. In the first of these forms the disease appeared in such a manner, that if we were to be guided by the description given in any of our standard medical treatises, it would be impossible to detect, or even to suspect, the existence of inflammation of the pericardium. Thus the premonitory symptoms were mild, consisting in some pain in the precordial region, a little cough, and very slight fever, which did not prevent the patients from pursuing their ordinary occupations, or even laborious employment. After one or two weeks they came to the hospital on foot. Nothing in the patient's countenance of a general bearing, indicated the existence of a severe malady; the face was calm; the skin quite cool; the pulse moderate, and, we again repeat, without the assistance of percussion and auscultation, it would have been quite impossible to detect the change which had

taken place in the cavity of the chest. Pain in the precordial region seems to be a symptom much more frequently existing than authors generally describe it to be. Thus in all the cases observed by M. HACHE, the development of pericarditis was marked by some pain, at times slight, near the left mamma. The same result is obtained by examining the twenty-two cases detailed by M. LOUIS and M. BOUILLAUD, while in a moiety only of those published previously to the memoir of M. LOUIS in 1826, the presence of pain about the precordial region is mentioned. Palpitation is another symptom which frequently attends pericarditis. It is, indeed, mentioned by all writers, but it may not be useless to give, what we may call, some statistical notes of this symptom. It was present in all the eight cases of M. HACHE. In the twelve cases of pericarditis published by M. LOUIS, it is mentioned six times. Thus we have palpitations existing in fourteen out of twenty cases. However, if we analyze the twenty-eight cases published by M. BOUILLAUD, we find palpitations mentioned only three times. How is this great difference to be explained? In many cases of pericarditis, the palpitations do not cause much distress, or attract the patient's attention, and we think with M. LOUIS, that if palpitations are not mentioned by M. BOUILLAUD in more than three cases out of twenty-eight, it is because his attention was not directed to that point. This circumstance shows the necessity of noticing, as well those symptoms which are absent as those which are present, if we desire a case to possess the full value of which it is capable. It is a point upon which M. LOUIS insists with some earnestness, and is one of which English writers are by far too negligent.

The rational signs of pericarditis are, as we have before said, insufficient to demonstrate the existence of this disease: fortunately the physical signs are much more certain; they are given at length, and with clearness, by M. HACHE. Before entering on an examination of these signs, we should mention that the author seems to refer constantly to cases of pericarditis with abundant effusion, and not to the dry variety of Dr. STOKES. One of the first physical symptoms worthy of notice is a prominence over the precordial region, depending evidently on protrusion of the soft thoracic parietes by the distended pericardium; this symptom was very well marked in five of M. HACHE's cases. In one it was slight; in two young girls it could not be determined; but there the disease was very slight, and if a small difference existed between the two sides of the chest, it was masked by the volume of the breasts.

Sonority of the Chest.—In all cases percussion gave a dull sound over the whole of the precordial region, and above this, along

the sternum, as far as the third, second, or even first rib. As resolution took place, this region became sonorous from above downwards, but in many subjects the sound remained obscure beyond its usual limits, at the time they left the hospital, all other symptoms having completely disappeared.

Auscultation.—In all cases the respiratory sound was absent, or more or less weakened, in the whole of the space occupied by the distended pericardium. This symptom evidently depends on the portion of the left lung which commonly covers the heart, being pushed on one side. As the effusion was taken up, the respiratory bruit reappeared, from above downwards, in the space where it was before absent.

Sounds of the Heart.—In cases of effusion, the normal sounds of the heart are obscured and displaced; being more evident at the level of the third rib than elsewhere. The rhythm was altered in three cases only, and then in a cursory degree. M. Louis observed the same irregularity in two cases out of eight; and in fourteen cases of cure, reported by M. BOUILLAUD, we notice it only once. Hence irregularity in the pulsations of the heart exists only in one-fifth of cases of cure, and that in a momentary manner. It cannot be regarded as an important character in the diagnosis of simple pericarditis; it seems to belong rather to that acute and complicated affection of which pericarditis forms only an element.

Abnormal Sounds.—The bruit de frottement existed in only three out of the eight cases observed by the author: in eight cases reported by M. Louis the same bruit was absent; however, it must be remarked, that at the time the patients were examined, the pericardium was the seat of more or less abundant effusion. The three cases in which the bruit de frottement was heard, occurred in subjects who laboured under the disease for a great length of time, and it appeared at a period (23rd to 25th day) when the symptoms evidently showed that absorption of the effused fluid had taken place in part. In two cases this bruit continued only three days, was not very distinct, but superficial, and was not accompanied by vibration of the thoracic parietes. In the third case the bruit de frottement was very strong, and at its commencement presented the timbre of a sonorous bruit de cuir. During the last four days it was attended by a vibratory thrilling of the thoracic parietes, circumscribed, at first, like the bruit de frottement, to the portion of the third intercostal space that joins the sternum at the left side, it then extended to the whole precordial region, and disappeared gradually with the rubbing sound. The latter bruit ceased suddenly on the 12th day after its operation, when the increased prominence over the precordial region, and matity, announced a

fresh effusion. Four days after this relapse the bruit de frottement reappeared, but with less force, and was attended by no vibrating thrill. M. Hache says,

"These details confirm fully the result of the observations published by Dr. STOKES in the *Dublin Journal*, on the mode of apposition and formation of the fremitus vibratoire. It is developed under the same circumstances as the bruit de frottement, but much more rarely. In the cases reported by M. BOUILLAUD it is noticed only once, and then described as a *new* species of fremitus cataire.

"Thus, in thirteen cases of pericarditis, where the bruit de frottement was distinct, the fremitus was only observed twice, or in one-sixth of the cases; but as the bruit de frottement itself exists in only half the number of cases, it follows that the phenomenon discovered by Dr. STOKES exists only once in twelve cases, and must, therefore, be of secondary importance."* In one case the author observed the metallic tinkling at a time when the effused fluid was nearly absorbed; M. BOUILLAUD has noticed the same sound in several of his cases. We do not propose to follow the author through the analysis which he gives of other symptoms furnished by lesions of innervation, of circulation, or nutrition; let us,

* We have given the very words of M. HACHE, or nearly so. It is evident that he has not read the paper of Dr. STOKES, or has been led into error by an imperfect translation. In the first place, the object of Dr. STOKES's paper was not to prove the existence of fremitus as a diagnostic sign of pericarditis, but to direct our attention to the value of stethoscopic phenomena, and chiefly to the bruit de frottement, in the diagnosis of pericarditis. Again, Dr. STOKES does not describe the vibratory thrill as existing in all his six cases; and, finally M. HACHE's statistics are evidently erroneous when he says, "in thirteen cases where the bruit de frottement, or de cuir neuf, was observed, the fremitus was perceived only twice," because a few lines before this he quotes Dr. STOKES's authority for six cases, in which these two symptoms coincided together.

Since writing the above observations, we have referred to the number of the *Archives G n rales* (for January 1834), in which Dr. STOKES's paper is translated, and we must say, in justice to that excellent journal, that the translation is perfectly correct, and that the errors of M. HACHE must be placed to his own account.

however, say a few words on one symptom, which, if our memory does not deceive us, is given as a frequent attendant upon pericarditis; this is fainting: it was observed in two cases only, where the disease was complicated by other grave affections: one patient suffered under this symptom at the commencement of the disease; another felt faint whenever he attempted to sit upright. The same phenomenon was observed only once by M. LORIS, and once by M. BOUILLAUD; never in simple cases of pericarditis. Fainting, then, does not belong to pericarditis, and may, in all probability, be attributed rather to the dangerous complications which exist in all cases where this phenomenon manifests itself.

Diagnosis.—In the cases observed by M. HACHE, the pain about the precordium, palpitations with or without dyspnoea, troubled dreams, or sudden awaking with fright, were nearly constant symptoms; but these are not sufficient to determine in a certain manner the existence of this disease, which can only be discovered by exploration of the chest. Then the development of the left side of the chest, the dulness of sound over the whole precordial region, with absence of the respiratory sound in that space, the displacement of the sounds of the heart, frequently attended with absence of impulse,—all these signs indicate the presence of effusion into the pericardium, and are the more important, because in most cases inflammation of that membrane determines effusion, and we are rarely called upon to examine a patient in the first days of his disease. These observations apply only to pericarditis with effusion; the author has not had an opportunity of seeing what Dr. STOKES calls the dry variety.

The march and termination of simple pericarditis are usually favourable. The disease terminates by cure from about the 15th to the 22nd day, under the influence of antiphlogistic treatment; however, this malady is more frequently complicated than simple: thus in five of the eight cases reported by M. HACHE, he observed the following complications; in one inflammation of the lungs; in two rheumatism; in two tubercles. The coincidence of rheumatism is regarded as very frequent by M. BOUILLAUD, who says "rheumatismal pericarditis is incomparably more frequent than any other species; it exists in about the half of all subjects affected with severe articular rheumatism." This assertion is rather too general; in comparing the cases reported by M. BOUILLAUD, ANDRAL, Dr. STOKES, LORIS, and M. HACHE, have a total of 72, and find that acute articular rheumatism existed only sixteen times, or less than one-fourth.

The age and sex have a certain influence in the frequency of pericarditis. Thus the oldest of M. HACHE's patients was 38 years of age; of fifty-five cases contained in the

works of ANDRAL, LOUIS, and BOUILLAUD, we find only six whose age passed 40, and the majority was below 20. Pericarditis, then, is a malady of young persons, but it is much more frequent in the adult than in the child. Females are less subject to the disease than males. In 107 cases collected by M. LOUIS, we find 27 women, 80 men; and in the 36 observations of M. BOUILLAUD, we have only 7 females, 29 males. It is unnecessary to enter into any details upon the treatment of this disease by M. LOUIS. In all cases, a moderate antiphlogistic method was employed with success. Digitalis was administered to five subjects during a period of from six to thirty days, one grain the first day, carried gradually to six grains in twenty-four hours: in two cases it produced a manifest lowering of the pulse, but the other symptoms were not relieved in proportion, and the pulse soon rose again, although the medicine was continued for a length of time and in elevated doses.

THE LANCET.

London, Saturday, February 13, 1836.

NEVER was there a more favourable period than the present for promoting a little gentle agitation on the subject of medical reform. But although there is an overflowing catalogue of abuses which require to be demolished, yet there are questions standing apart for consideration, which are altogether unconnected with the misgovernment and malpractices of our medical colleges, corporations, and hospitals. On some points a great difference of opinion prevails, many contending that a liberal system of government would be injurious to the interests of the community, while others believe that if the self-perpetuating principles in the election of the rulers in our colleges were abolished, good government in medical matters would be the certain and speedy result.

There is one grievance, however, which, although it is itself the source of much heart-burning and injustice, does not owe its origin to any enactments of the Legislature, or to any charters granted by the Crown.

We refer to the unjust treatment to which medical practitioners are subjected, who attend as witnesses at Coroners' Inquisitions. We, therefore, earnestly and emphatically entreat our professional brethren to use their utmost endeavours to obtain support for a bill which, in all probability, will be placed on the table of the House of Commons on the 2nd of March next. The mode of proceeding in that as in every other case in which the interference of Parliament is required, is by petition; but we would remark here, that it is a great mistake to suppose that one petition, however numerously signed, is, or can be, equal in influence to a great number of petitions coming from various cities, towns, and other places in the country; because in the latter case a numerous body of members of both houses of Parliament will be enlisted on the side of the profession. If there be but *one* petition, it can be presented by but one member. If there be numerous petitions, they are necessarily placed in the hands of *many* members, who are then made to feel an interest in the subject, which could not from any other circumstance occupy their minds. Besides, each petition may ensure an application by letter, or a personal interview, or, at any rate, some communication between a medical practitioner and some member of Parliament with whom he or his brethren may be acquainted. Had we anything to fear from an investigation of the subject, we might be chary and cautious in hazarding such applications, but the demand of medical witnesses to be paid for the time and services required in attending at Coroners' Inquests, is founded on such a just and immovable basis, that no danger can arise from its discussion,—none from the severest scrutiny into the correctness of the claim. What, we ask, is the value of the inquest, in five cases out of ten, unless there be a medical witness present on the occasion? And what right have the public to insist that the professional services of a

medical man shall be devoted in aid of the proceedings at a Coroner's Inquisition, without making him an adequate return in the way of compensation? In fact, the entire proceeding, in many instances, constitutes a worthless, nay, even a mischievous farce, in consequence, almost entirely, of the want of a law which authorizes the coroner to direct the payment of a sufficient sum for medical attendance. Be it observed, too, that a medical witness, on being summoned to attend at the inquest, is liable to be committed to a jail, in contempt of the mandate of the Court, if he omit to be present at the inquiry. Ought such a state of the law to last? Is it possible that it can last much longer if the medical profession discharge their duty to themselves and the public? This is a public and not merely a professional question. The welfare of the community is the point at issue. Often as we have thought and stated that the Court which is held by the Coroner, is one of the most important institutions in the kingdom, never has it struck us as being so vitally momentous as when we have reflected on the great value of the efficient and honourable medical testimony of witnesses who have been educated in the science of medicine. Even if the Coroner were himself a medical practitioner, it should be recollected that he is not a witness in the inquiry; but where the Coroner is not a medical practitioner, as we have a thousand times alleged he ought to be, in one half of the inquests that are held the money which is paid out of the county rates for the expenses of the Court, might as well be tossed into a river. Preposterous indeed, in this latter case, is the whole proceeding. It is then nothing but a solemn farce, which is calculated to lull unreflecting and ungifted spectators into a state of pernicious delusion.

It may be alleged that witnesses are not ordinarily reimbursed in our Courts of justice, except for the bare expenses which are consequent on their attendance. The

parallel, however, does not hold when it is attempted to be drawn between such persons and medical practitioners who give evidence at Coroners' Inquests. In the one case the witness generally attends because he was accidentally cognisant of the facts on which he is to be examined. In the other case the witness attends officially, and the value of his testimony depends on the time and money he may have devoted in order to acquire a scientific knowledge of his profession.

Again. Without such testimony, the inquest is useless to the public. And, yet further, the entire duty of this attendance is necessarily restricted throughout a whole district, to the few practitioners who may be resident within its circle. Upon a very few persons the toil and responsibility of attendance on these occasions imperatively devolve. Upon what principle of justice, therefore, can a very few gentlemen, who have expended many years of their time, and many hundreds of pounds of their capital, in the mere attempt to render themselves competent to execute the general duties of their profession, be required to make,—systematically and regularly make,—the heavy sacrifices which the summonses of the Coroner usually demand? On our side of the question the entire justice of the arguments rest. On the other side of the question,—if there be an opponent,—he can be armed only with the weapons of prejudice. In the face of such instrument, the advocates of a correct principle stand in no danger.

But we must not remain passive and quiet in this emergency. It were folly, indeed, to continue gazing, stupidly gazing, at the progress of events, without taking some pains to turn the current of improvement to our own and the general advantage. *All that is*, every friend to the cause of medical justice, should resolve to take part in the struggle. No doubt can be entertained of the successful progress of the MEDICAL WITNESSES BILL through Parliament, if

medical practitioners will but use their influence in sending petitions, short petitions, to members of both Houses of the Legislature, praying that such a measure may be enacted into a law. We say to members of both Houses of the Legislature, because it is of the utmost consequence that an impression which is produced in one House of Assembly should not experience a counter-vailing check in the other.

It should be understood, also, that it is not necessary that the petitions should be written on parchment, as a sheet of common writing-paper is amply sufficient for the purpose.

Beyond praying for such remuneration as the Houses of Parliament may consider it wise and just to grant, it will only be necessary to point out the hardships to which medical practitioners are subjected by their being so often required to attend at inquests which are held many miles distant from their places of residence, occupying many hours of their time in the journey and in waiting during the progress of the proceedings. The folly, also, of drawing money from the county fund for the payment of the expenses of an inquest when efficient medical testimony is not received, should be shown, and allusion may with propriety be made to the necessity of instituting post-mortem examinations for the information of the coroner and jury, and of the danger to life which often attends such investigations.

And now let us hope that this grievance will no longer exist from want of applications for redress, or indisposition on the part of the Legislature to grant what is so truly and unquestionably just. Let us hope that a wiser state of things will arise out of the simultaneous exertions of the medical practitioners of this empire. Let it especially be remembered that no good result can follow any efforts which may be made, unless both houses of Parliament become the points towards which every effort is directed. Finally, we conjure every surgeon who may

this the greatest metropolis of the world. You have shone with equal brilliance in the Court and in the College. The polish and suavity of your manners have rendered you as acceptable at the banquets of great peers, as at the tables of commoners; and, as I have heard you yourself so justly observe, your presence at the hospitable board of our beloved Sovereign has absolutely conferred a distinction on the College, and is an honour to the profession generally. Now let me contrast with this, your true and just character, that of the ephemeral reptile, the mushroom, the mock surgical reformer. In place of the classical and moral education which you received at Oxford, and the elegance of manners and ideas which you there acquired, he spent all his time within the precincts of an Institution, where, instead of being occupied in those pursuits which expand the mind and ripen the understanding, he was employed as the dirty drudge of the Hunterian robber, whose example,——Alas! we are all creatures of habit, and most of us are more prone to follow the path of evil than of good,—to become the leader of a set of corruptionists than the peaceful advisers of liberal and independent men.

"I have thought it proper to draw your attention to this subject. It is for you to consider what reliance should be placed on those who now ostensibly co-operate with you in your arduous endeavours to obstruct the progress of the Metropolitan University.

"Whenever you contrive to see Mr. SPRING RICE, pray fail not to tell me the results. It is better that I should communicate with the Fellows on the matter. You may be committed in the proceeding.

"Have you heard that the Council of the College of Surgeons have applied to the Bishop of LONDON to write a Latin inscription for their new building? I suspect that BRODIE is at the bottom of this, and that there is some peculiar object in the request. I also hear that the little man has been intriguing to get some relation of his own appointed as trustee to the Hunterian Museum. I have no doubt that he has a *good* intention in this; but he seems never to be at rest.

"Your faithful and devoted,

R.

"Monday."

"MY DEAR SIR,—Our matters regarding the University have been managed much as I anticipated. Sir BENJAMIN having procured an interview with Mr. SPRING RICE, with whom he assumed the character of a liberal, he got the Chancellor, step by step, to consent to see me. I soon found out, however, at my interview, that we had little to expect from Mr. RICE.

"I began with explaining to him how earnest our College was to reform itself, and I assured him that in the course of one or two years the thing would be done satisfactorily to all parties. I explained to him that our great difficulty which we had to surmount was now got over by the deaths of TOTHILL and MARON, whose bigoted and contracted minds would not allow them to listen to any plan of reform, and that the few superannuated old dowagers who remained in the College would, in the course of nature, soon leave this world of sorrow, and thus would enable us younger Fellows, to sweep away those abuses which are so loudly complained of. I must confess that all I said seemed to make little impression on the mind of the Chancellor. I could distinctly perceive that our foes had been there before us, and that it is determined to overthrow the present medical corporate bodies. He evidently saw the motives which had influenced BRODIE, and CHAMBERS was much too thick-headed a fellow to alter his views. In fact, it now appears to me next to certain, that a metropolitan university will be established, on the broadest possible basis, granting degrees in medicine and surgery on such terms as will best ensure to the public competent medical men, and permitting those who may obtain such degrees to practise their profession freely, without molestation, in all parts of the British dominion. When such a plan is carried into execution, what will become of us? Who will rule in Pall Mall East? What will be the condition of the Deng Company in Blackfriars? Who will come forward with fifty-pound Bank-notes to purchase our license? Who will then be at the trouble of trotting his tertius at Oxford or Cambridge for a medical qualification? I certainly do not care so much about the change in Lincoln's Inn-fields, and, indeed, I agreed with Mr. SPRING RICE, that not one of the men of that Council ought to have anything to do, directly or indirectly, with the Metropolitan University.

"I have finally arranged to commence our evening entertainments at the College on the 2nd, when I shall have an interesting oration to deliver. In the interim I am giving a series of snug little dinner parties, at one of which I invited Dr. WILSON, in the hope of soothing his feelings of opposition. There is, however, a lamentable inflexibility about him which will give me some trouble. I have heard that he made a direct attack on poor McCLOUD in the board-room of St. George's the other day, as the editor of the Gazette. Ever yours,

"H. H.

"Thursday."

MEDICAL ATTENDANCE ON THE SICK POOR.

To the Editor of THE LANCET.

SIR,—I beg leave to offer my mite towards the general fund of plans concerning this important and humane question.

1. The parish officers should submit to view, in a public place or at an open vestry, a list including every pauper in the parish who cannot afford to pay for medical aid in case of sickness. The list to include every individual member of a pauper's family who is unable to gain a livelihood.

2. Every pauper or indigent labourer who claims a place on the medical list, to have his claims openly heard and discussed once a-year by the parish officers and the parishioners who pay the taxes.

3. After having made the list, the parish should agree with a medical officer to attend every person named in the said list, in case of sickness, for one year, at some fixed price, say fourteence per head in the country, and tenpence per head in the town. If we consider that poor families are generally very numerous, about fourteence will come near the mark; and if midwifery be included in the agreement, an additional sixpence should be added to each name on the list.

4. The medical candidate should be proposed by the guardians or the parish officers, and be elected by ballot, by those only who are on the list of paupers; by which means the paupers would be less liable to the abuses of a bad election. The paupers, also, would thus have some claim on their doctor's complacency and attention, as the voters have on members of Parliament.

5. Should sickness occur to persons not named in the list, yet who are unable to pay for medical attendance, such cases to be considered as common cases, not belonging to the agreement, and to be paid for *extra*, accordingly, by the parish. This extra payment will meet the miserly design of not placing on the list several who may have a just claim to be there. One such case would prove the wisdom of placing a dozen more names on the list.

Supposing a parish to contain fifty paupers who receive a weekly allowance, probably there will be two hundred entitled to have a place on the medical list. If these be taken at 1s. 2d. per head, the sum would amount to 11l. 13s. 4d.; and if 6d. towards midwifery be added, it would amount to 16l. 13s. 4d., which in a country practice is little enough.

This rate of payment is but very moderate, but then the practitioner does not expect to *fatzen* by means of poor patients. Although the poor form an important part

in the chain of society, yet the practitioner's principal reliance must be placed on the increase of his connections and usefulness through their means. The foregoing plan seems to me to be as simple and just as the nature of the circumstances concerned will allow; requiring, indeed, several modifications as to a fixed salary, &c. I am, Sir, yours respectfully,

CORVINUS.

Corwen, Feb. 8, 1836.

MEDICAL ATTENDANCE ON THE SICK POOR.

To the Editor of THE LANCET.

SIR,—So much has been said in THE LANCET on the mode of procuring medical attendance for the sick poor, and the remuneration of the practitioner, and it has been said so well, that little remains to be usefully offered. However, a few observations on the subject may not be superfluous. At the same time I take the opportunity of congratulating the profession on the prospect of the whole mass of absurdities which constitute the laws for regulating (!) medical practice, being brought before Parliament through the medium of the Editor of THE LANCET.

The medical clauses in the Poor-Law Amendment Act in no respect contemplate an increase in the effectiveness of the medical profession, and the preservation of the health and lives of the poor.

Even if I approved of the mode on which medical men are elected as attendants on the sick poor, I could find numerous errors in the details, but this would be useless, as I object *in toto* to the principle of contract—to the letting out of medical services to hire for a specified period of time, at all hazards, "come weal come woe." Moreover, it is not honest to either party, as it implies in each a feeling of distrust. On these grounds I and my predecessors have at all times refused to be parties to all medical contracts, and consequently for years have not attended any "parishes." Of course also we have declined any participation in the plan under the new Act, which therefore does not in any way affect my interests. I have thus, too, avoided the numerous disagreeable circumstances which are so frequently complained of in parish medical competition, from the eagerness with which medical men have caught at the depreciating offers of contracting overseers, jostling and jockeying each other in the scramble. Indeed, the present degradation of the profession seems to be self-sought and self-invited.

I do, therefore, on every ground agree with you in the opinion that medical men

must rely only on themselves and the legislature for redress under the numerous evils arising from the present anomalous and unjust laws. As for the poor! may God help them. If the Malthusian doctrine be good, commend them to the tender mercies of enlightened commissioners, who confide them to the care of "American" practitioners, *sans* "catheter," *sans* "horse," *sans* everything.

With regard to remuneration, I think the following mode would be advantageous. In cases beyond a certain distance (a mile?) a *mileage* should be charged. For the case itself, whether in town or country, a charge should be made in the ratio of its duration,—a certain sum per day, gradually diminishing after the first three days. Thus for a continued chronic case there would be a smaller *rate* of pay, and in an acute case of shorter duration, when more time and trouble are bestowed, the rate of remuneration would be somewhat greater.

Under such arrangements the poor might apply to whom they pleased, each practitioner at certain periods giving in (as directed under the new Act) the names of those patients who have been under his care, with an account of the nature and duration of their disorders. I am, Sir, yours obediently,

A COUNTRY PRACTITIONER.

Cirencester, Feb. 9, 1836.

POOR-LAW AMENDMENT ACT.

To the Editor of THE LANCET.

SIR,—The following statement will prove the hardship of my case under the Poor-law Amendment Act. Three years ago I engaged in a practice of sixty years' standing, which comprised the medical attendance on five parishes in my immediate neighbourhood, but which five parishes will not give me sufficient interest to obtain the attendance on the poor in the district, in consequence of the sudden introduction of strange medical men by the Poor-law Commissioners. I shall not be able to retain even the one parish in which I reside. The consequence will be, the entire destruction of my practice, the committal of a dead robbery on my property, with the prospect of starvation to the sufferer. The Guardians, after allowing a certain sum for a certain number of attendants, should, at least, divide that sum amongst the established medical men, allowing them to remain undisturbed. I transmit you my name and address privately, and am, Sir, your obedient servant,

A SUFFOLK PRACTITIONER.

MEDICAL CORONERS.

To the Editor.—SIR, As you desire to be informed of the medical coroners residing in the vicinity of the numerous readers of THE LANCET, I beg leave to state that the coroner for the county of Merioneth, is EDWARD WILLIAMS, Esq., of Bala, surgeon. In the next county to this, the county of Denbigh, there is also a medical coroner, R. NICHOLS, Esq., surgeon, of Ruthin. Thus it would seem that we are wiser in Wales than they are in England,—two at least of its counties having chosen their coroner from among the members of the medical profession. I am, Sir, your obedient humble servant,

JOHN WILLIAMS.

Corwen, Feb. 8, 1836.

MR. SMITH'S INDENTURES.—To the Editor.—SIR,—In answer to an inquiry made in the last number of your journal, by the author of the letter signed "INVESTIGATOR," I hasten to furnish him with a statement of the simple facts. About half an hour before my examination terminated, the Clerk of the Court gave me my indenture of apprenticeship, which I placed by my side, when the examiner who was sitting opposite to me, whose name I have not the pleasure of knowing, took it up and looked at it. The rest of the proceeding has already been made known. Now if this mode of proceeding be irregular, which the author of the letter in question considers it to be, I am only performing a proper duty in stating the facts, in order that a similar proceeding may be prevented in future. You will oblige me by inserting this note in the pages of your very excellent journal. I remain, Sir, your obedient servant,

THOMAS SMITH.

1, Jewin-crescent.

To the Editor.—SIR, I beg to state, through the medium of your journal, that I have no knowledge or concern with certain individuals who have taken the liberty to affix my name to a preparation of *Sarsaparilla*, by printing it on the stamp,—as declared, at least, in certain advertisements. Nor have I, as I find it is asserted, anything to do with *sarsaparilla*, or any medicinal preparation whatsoever. Permit me also to state that legal measures will immediately be commenced in order to obtain redress for this most unjustifiable freedom, or forgery, as perhaps it might be designated. I am, Sir, most respectfully, your most obedient servant,

JOHN HANCOCK.

Commercial-road, Feb. 1836.

HERVIST STREET HOSPITAL, DUBLIN.

CLINICAL REMARKS*

BY

DR. WALLACE.

SECONDARY SYPHILIS.

January, 1836.—*Ward No. 8.* The case of this individual (Mary Ross) deserves your particular attention. She is, I presume, from her appearance, only seventeen or eighteen years of age. You observe she looks full, and in rude health. She, however, labours under secondary syphilis, and the manner in which she contracted the disease, as well as the form of her symptoms, should be known to you, and impressed upon your memory. *First*, as to the manner in which she contracted the disease: she affirms, and I am perfectly convinced of her veracity, from the inquiries and examinations which I have made, that she contracted it from a child which she *dry-nursed*. Remember I have said *dry-nursed*. It is generally known that *wet* nurses often contract a disease from suckling infants labouring under symptoms of syphilis; but I do not know that it is generally admitted, that the *dry* nurse may also, by the contact of such a child, become diseased. This is however the fact; here is a proof of it. Numberless are the analogous cases which I have seen. I have known the disease to be propagated through whole families, yea, through a whole village, by simple contact. In all these cases, it is the matter of secondary sores which propagates the disease. You know that Mr. Hunter and his followers deny that secondary syphilitic sores are infectious or contagious. In this position they are quite mistaken. This is one of the numerous facts which my investigations have unfolded. The second point of attention in this girl's case, is the form of the symptoms. She has condylomata on the pudenda and round the anus, and you may here see that she has a fungoid excrescence on the surface of her tongue. You also remark that the front arches of her soft palate are ulcerated, and that the ulceration is of that superficial form which I have often told you almost uniformly accompanies condylomata. You also see that

* Dr. Wallace gives clinical instruction in two forms, by conversation at the bedside of the patient, during his walk through the hospital, and by lecture in the theatre of the hospital. The former are here called his "CLINICAL REMARKS," and to the latter we have prefixed the title of his "CLINICAL LECTURES."—*Ed. L.*

she has, scattered over her shoulders and arms, a number of some what rounded spots, of a red-brown colour, very slightly raised, and scaly, scarcely larger than a split-pea. With these symptoms she has no pains, nor any affection of the fibrous, articular, or osseous systems. She has, in fact, the majority of those symptoms which you will find to occur in all the cases of syphilis which are produced by secondary matter. You have seen the child from whom she contracted the disease, and went to Fenglis for the purpose, and it labours under the same class of symptoms. I am anticipating by these remarks, gentlemen, some of a most important series of facts which I have discovered respecting the cause of the varieties in the symptoms of syphilis; and which I will very soon take an opportunity of communicating to you in a systematic form. The symptoms of syphilis under which this girl labours, yield with great rapidity to mercury, and are comparatively insensible to the action of the hydriodate of potash, which is, in some other forms of syphilis, a remedy far superior to mercury.

ULCERATED SURFACES.

February, 1836.—*Ward No. 4.* See how admirably this man's case is advancing to a cure! Can anything illustrate in a clearer light the value of my mode of treating old ulcerated surfaces? He had lost, from sloughing and ulceration, consequent on an injury, a large portion of the integuments on the inner surface of his thigh; and an extensive ulcer remained, which he could not get healed. He says he had applied to many persons, and had tried in vain all the ordinary applications and methods. When he was admitted, the ulcer was not less than eight inches long and three wide; and the skin surrounding it was very indolent, or callous. You see it is not now more than five inches long, and in some parts scarcely half an inch wide, and the surrounding integuments are much softer and more natural. How has this great improvement been so rapidly produced? You have seen the treatment; he has been kept in bed, the surface of the granulations has been dressed with water-dressing; that is, lint dipped in tepid water has been daily applied to the sore, and then covered by oiled silk; and the skin surrounding the sore has been, to the extent of an inch, several times rubbed with the solid nitrate of silver, previously dipped in water. This application, you see, causes the separation of the cuticle, and a temporary exhalation, or sweating, from the surface of the cutis.

Let me explain to you the principles of this treatment. You will find, if you attend to the subject, that old chronic ulcerations are prevented from healing, much more by a morbid state of the tissues immediately surrounding, and under, the diseased sur-

face, than by the state of the diseased surface itself. Or, perhaps, it would be more correct to say, that they are prevented from healing, not only by the state of the diseased surface itself, but by the state of the surrounding parts, upon the healthy action of which, the reparation of the ulcerated surfaces, mainly depends. In the treatment of such cases, however, practitioners seldom think of the surrounding parts. They apply dressings of various kinds to the surface itself, and seem to think nothing of the parts upon which the surface is placed, unless so far as they act on them by bandaging and by position.

My *first* object in the treatment of such cases is to leave the surface as much as possible undisturbed,—to let the regenerating lymph, when effused, remain without interruption; I do not allow the surface to be cleaned in such a way as to cause the slightest friction. I avoid all stimulating applications, which, although they may be of the mildest kind, too often cause the destruction of the very weak granulating germs, and thus undo daily what nature in her attempts at reparation is endeavouring to accomplish. To carry my first object into effect there is no mode of dressing to be compared with the water dressing, laid on with great gentleness, and removed only when there is an accumulation of discharge. My *second* object is to excite and alter the morbid state of the parts, upon which the ulcerated surface is placed, and to this end I stimulate, or act on, them with the nitrate of silver, applied as you have seen it applied by Mr. Molloy in this case. By this method, conjoined with an occasional purge, you will succeed in healing old sores, which can be healed in no other way, and in a surprisingly short time. And let me add, that a sore so healed is much less likely to re-ulcerate than one healed in any other manner. This I would explain by the fact that it is a mode of treatment which, by causing a healthy action in the surrounding parts, produces a sounder cicatrix, and consequently one more able to preserve its future integrity under exertion. You know that this practice differs widely from that of Mr. Higginbotham. He applies the nitrate of silver to the surface of this sore, as well as to the surrounding parts; but I have found this quite unnecessary, and greatly to retard the healing of the sore, as well as to cause unnecessary pain. Let me, however, recommend in the strongest manner to your perusal, Mr. Higginbotham's work. It is a most valuable contribution to surgery.

NORTH-LONDON HOSPITAL.

ERYSIPELAS OF THE HEAD—USE OF THE EXTRACTS OF ACONITE AND BELLADONNA.

CATHERINE COX, aged 25, was admitted February 4, with erysipelas of the face, under the care of Mr. LISTON. She is married, and has had four children. She states that she has been subject to attacks of erysipelas for twelve years past, which have come on at all seasons, and without observing any regular intervals, sometimes a very few weeks intervening between them, and lasting for a fortnight or three weeks at a time, the cures not being completed under three weeks. She has, however, been quite free from the affection for the last four years. The evening before her admission she had become very much heated with washing having at the time her catamenia upon her. She was attacked with rigors, succeeded by pyrexia, and sharp burning pain about the eyes. The catamenial discharge was also suppressed. On her admission into the hospital, the following symptoms presented themselves:—Great redness and swelling of the whole face; the left eyelid so puffed as completely to obstruct her sight; pulse 116, small, and hard; tongue moist and clean, bowels costive; great heat of the skin; severe pain in the head. Fomentations were used to the part every two hours, and an opening draught, containing the sulphat and carbonate of magnesia, with antimon wine, was given directly.

Feb. 5. Has passed a restless night; the erysipelas has extended over the left ear to the occiput; pulse same as yesterday; bowels opened by the medicine; great heat of skin and thirst; the catamenia have reappeared. Two tablespoonfuls of a mixture, containing one grain and a half of aconite and four ounces of water, were given every three hours.

Ten p.m. Has taken three doses of the aconite mixture. Pulse 108, softer; skin moister and softer; not so restless; she has a slight rigor about an hour ago. A mixture, containing one grain of the extract of belladonna in sixteen ounces of water, was now ordered, of which she took two tablespoonfuls every three hours.

6. Redness and swelling are much diminished; she has had a very quiet night, skin covered with a gentle perspiration, pulse 96; tongue moist and clean. She complains of no pain, and expresses herself as being a great deal better. As the bowels are confined, give a dose of castor oil. The belladonna mixture to be given every five hours.

7. Nearly convalescent; the redness has entirely disappeared; some oedema still remains about the orbital regions; the rest of the surface is wrinkled, and is desquamating; pulse 96; tongue clean; bowels

open. Discontinue the medicine. A pint of beef-tea daily.

9. Quinine recovered, having been under treatment on this occasion only four days. It is ascertained that aconite has superseded bleeding in many cases at this hospital.

DELIRIUM CUM DEBILITATE—IMMENSE
DOSES OF THE MURIATE OF MORPHIA.

Timothy Quill, aged 38, was admitted Dec. 18, under the care of Dr. ELLIOTSON. He is an excavator, a strong and muscular man. He has been much addicted to drinking spirits, particularly rum, and has been considerably exposed to vicissitudes of the weather, and to noxious effluvia, such as those arising from common sewers. On his admission he told a story about the origin of his illness six months ago, of its seat in the right side, and at the epigastrium; of his travelling to Ireland for the recovery of his health, and the return of the complaint on resuming his occupation; he complained of thirst, loss of sleep, and tenderness over the abdomen. These circumstances were related with perfect coherence of manner, but they turned out afterwards to be all entirely destitute of foundation. He was very restless during the night, often leaving his bed, putting on his clothes, wishing to go out of the hospital, accusing the other patients of robbing him, complaining of dimness of sight and spectral appearances, and other mental delusions. A slight tremor, after careful observation, was detected in his fingers and his tongue. He says he has headache, and that he is thirsty. His bowels are confined, tongue clean, appetite very good. Pulse 60, slow and weak.

Dr. ELLIOTSON considered this to be a case of delirium dependent on debility; but without the remarkable diagnostic sign of that disease. He therefore ordered the patient, on the day after his admission, to have half a grain of the muriate of morphia directly, to be repeated at bed-time if necessary.

21. Rather more tranquil.

22. Sleeps better at night, but still labours under delusions, and occasionally talks and mutters loudly and incoherently, and is so violent as to require to be pinioned.

23. Is more tranquil and rational to-day.

26. He was extremely violent the whole of yesterday, and to-day the fictions have again been employed. Muriate of morphia, half a grain, every fourth hour.

28. Was extremely violent the whole of yesterday. The morphia to be given every three hours.

29. Still violent; the dose of morphia every two hours.

30. The morphia increased to one grain every two hours.

Jan. 2. Seems much better this morning,

and gave rational answers to questions put to him.

4. Is rather quieter during the day, but becomes delirious, and is very violent every morning, between 3 and 4 A.M.

6. Muriate of morphia one grain every hour.

He was discharged to-day, in consequence of his creating such a noise in the wards.

COMPOUND AND COMMINUTED FRACTURE
OF THE OLECRANON.—FRACTURE OF THE
THIGH.—AMPUTATION OF THE ARM.

Charles Hussey, aged 36, a slater, was admitted October 15th, under the care of Mr. COOPER. He had fallen from a ladder, at the height of the third story of a house, in consequence of one of the steps breaking as he was ascending. The femur was broken transversely, at about the junction of the middle with its lower third. There was also a compound comminuted fracture of the olecranon of the left arm. With the point of the finger some fragments of bone could be felt within the wound, and one small piece was so loose, that it was taken out. The extremity of the olecranon was retracted by the triceps. The patient complained of pain in his side and back, where he had received some severe contusions. The thigh was put up with a long splint, in the straight position, and the elbow was extended by means of a splint in front of the joint, the arm having been previously bandaged from the fingers upwards. As a good deal of blood oozed from the wound, the sides of it were not brought together until the next day. A cold evaporating lotion was applied.

16. This morning a considerable swelling has extended up the limb, with ecchymosis over the olecranon; the bandage was therefore slackened; the man had passed a quiet night.

18. Not so well, has considerable fever; arm much swollen and discoloured; cuticle separating over the triceps; copious effusion of serum in the cellular tissue up to the shoulder.

20. Mr. COOPER visited the patient to-day; the bandages were removed, and a considerable quantity of pus, mixed with blood, allowed to escape from the wound. Mr. C. thought the man would have a better chance of living if the arm were amputated; but after a consultation with Mr. LISTON and Dr. QUAIN, it was decided to try to save the limb. Fomentations and poultices were ordered, and the arm was left free from all pressure.

30. Since the last report two or three abscesses have formed about the elbow, and been opened. During the last two days he has been exceedingly restless and delirious; his pulse has risen to 136. A grain of the muriate of morphia was given to him, and

he was directed to be kept under the influence of that medicine.

From this time the case got gradually worse; the patient was delirious almost every night; the hand was oedematous, and erysipelas had attacked the forearm and arm, nearly as high as the armpit, and matter was effused under the integuments. The pulse was varying from 130 to 150. As soon as the swelling and redness of the upper arm had somewhat abated, Mr. COOPER determined on removing the limb by the following operation:—An external flap was made, by introducing the point of a narrow smallish amputating knife into the centre of the posterior part of the limb until it touched the bone. The handle of the knife was then inclined towards the patient's side, and the point passed closely round the humerus, to the fore part. The external flap was then completed by carrying the knife through the biceps and centre of the front of the limb, and cutting downwards and outwards. The flap was two inches and a half in length. The internal flap was formed by introducing the knife at the upper and posterior angle of the wound, and passing it round the bone to the front angle of the first wound, and cutting downwards. The fibres of the brachialis and triceps were divided, and the bone was sawn through. Mr. COOPER said he was induced to remove this limb by the lateral flap operation; for, having written so much against it, it might be thought he was prejudiced against it, which was not the fact, and he would give it a fair trial by resorting to it in all cases in which he could. After the operation the pulse fell to 120.

Nov. 21. An incision was made into an

erysipelatous swelling which has taken place over the pectoral muscles; the inflamed skin had been bathed with the nitrate of silver wash.

Dec. The patient went on favourably. The stump coming to be an excellent one, the thigh also having united.

HOUSE OF COMMONS.

Thursday, Feb. 4th.—Mr. WAKLEY gave notice that on Tuesday, the 1st of March, he should move for leave to bring in a bill to provide a sufficient payment to all legally-qualified medical practitioners who might be called on to attend, in a professional capacity, as witnesses at coroners' inquests.—*Morning Chronicle*, Feb. 5.

CORRESPONDENTS.

The length of *Observer's* reply, and its late arrival, render it impossible for us to examine his statements with sufficient care for notice in our present number.

ERRATUM.—In the leader at page 753 of the last number of *THE LANCET*, the sentence beginning in line 21 of column 2, should have been printed thus:—"Not content with falsifying the conduct of the gentlemen (the students) whose temperate and admirable behaviour conferred a dignity on the deliberations of that assembly" &c. In a part of our impression the ninth word was printed "gentleman."

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XII.

ATROPHY OF THE BRAIN AND SPINAL MARROW.

GENTLEMEN,—Having finished in our last lecture the study of hypertrophy of the nervous centres, we now proceed to examine the opposite state, or lesion, which consists in a diminution of nutrition,—in an atrophy of the same part. This atrophy of the nervous centres may result either from a primitive arrest or retardation of development, or from an actual diminution in the bulk and volume of some portion of the cerebro-spinal axis, after it has been fully and perfectly formed. Hence flows naturally a distinction of this disease into

Two Principal Species.

The first is congenital, rather an absence of formation than a wasting of the medullary substance when once developed. It has been described by several authors, and particularly by M. CAZAUVELLH (who has published an excellent memoir on the subject in the *Archives Generales*, t. 14), under the name of Agenesia, cerebral agenesy. The other form of the disease is not congenital; it occurs at a certain period after birth; it does not depend on original absence of the part, but is an acquired disease, produced by causes that we shall presently have occasion to investigate.

No. 651.

General Anatomical Characters.

Atrophy of the nervous centres, gentlemen, whether it be an acquired or a congenital malformation, may present itself to our observation under a great number of forms and degrees, from the slightest diminution in the normal volume, either of the totality or any one portion of the cerebro-spinal axis, up to the complete absence of all those parts together,—of the brain, the medulla oblongata, and its prolongation into the cavity of the vertebral canal. Between these two extreme cases we find an immense number of intermediate degrees, to the principal of which we shall presently recur in detail. No matter what may be the seat or degree of this atrophy of the nervous centres, the disease is recognised by a certain assemblage of anatomical characters, which we now proceed to lay before you. The gray substance enveloping the medullary pulp is more pale than natural. It very frequently retains its normal degree of consistence; but in some cases we find that the nervous substance has acquired an increased degree of density and consistence, at the same time that it has diminished in volume. The brain then appears more solid than usual; it has a harder pulp, and this is particularly the case when the atrophy attacks the convolutions or external layer of the cerebral mass.

The parts immediately surrounding the atrophied portions of the cerebro-spinal axis present sometimes certain lesions that we should not neglect to notice. These may affect either the membranes which envelop the brain and spinal marrow, or the osseous cavities enclosing the central mass of the nervous system.

When the Diminution of the Brain or Spinal Chord is very considerable,

the membranes take on an increased action, and throw out a quantity of serum in proportion to the loss of substance which the nervous centres have suffered. In these cases we find a large quantity of serous fluid effused into the general cavity of the cranium, or into the ventricles of the brain and between its different convolutions, occupying and filling up the void that has been

3 G

left by the atrophied brain; however, when the bones of the cranium sometimes the case, present an equal degree of atrophy, when the skull, as we may use the expression, follows the retreat of the brain, and is applied closely on its surface, then the quantity of serum is much less considerable, and the membranes display a degree of activity in harmony with the new object which they are called on to fulfil. It is not now the time to discuss where this serum is collected, or from what source it is more particularly derived. This question would lead us too far from the subject of our present study; however, we may remark that it would appear, from the researches which have been made by M. MAGENDIE, and at a still later period by M. le Docteur CAVARA, that it is accumulated in the cellular tissue which is interposed beneath the arachnoid membrane. In some cases the serum is not diffused throughout the surface of the brain, but is collected together in masses, contained in one or more cysts, which supply the place of the absent nervous substance.

The Osseous Envelopes,

which protect the cerebro-spinal axis, may also present various changes, corresponding with the lesions of the soft parts beneath. Sometimes the osseous parietes are intact; the form of the skull is perfectly normal, and in this case the void left by the atrophied nervous matter is supplied by an effusion of serum, which we spoke of a short time back. When the disproportion between the cranium and the cerebral organ is great, the serum is found in large quantities; in other cases, the deficiency of nervous matter is made up by peculiar changes in the organization of the membranes themselves; the meninges are found much thicker than usual; they are incrustated with a cartilaginous or even an osseous layer, more or less thick, according to the degree of atrophy of the brain.

You may remark the analogy existing between this latter circumstance, and what takes place in other parts of the body. Thus, when a portion of the lung has been destroyed or atrophied, a lesion that frequently exists at the summit, in consequence of abscess, induration, and various other accidents,—when this, I say, occurs, and, at the same time, the thoracic parietes are unable to accommodate themselves to the altered form of the lung, to follow its atrophy by a corresponding degree of contraction, we frequently find osseous or cartilaginous matter thrown out between the ribs and surface of the lung, nature thus endeavouring to fulfil, by a morbid process, an indication which the state of the respective parts rendered impossible by a normal process.

We have now alluded only to cases of atrophy in which the parietes of the skull did not present any alteration of form or

bulk, but this is not always the case; the osseous parietes of the cerebro-spinal axis more frequently indicate, by a various state of conformation, the different degrees of atrophy that exist in the brain. In some cases the bones are thicker than in the normal condition, and yet this increased thickness of the skull is not appreciable on external examination, because the inner table alone is the seat of an increased nuttition. Here we have no default of development in the bones, corresponding with the want of development in the brain; but, in other cases, this is more marked. Thus, in a certain number of examples, the brain is more or less atrophied, and at the same time the osseous parietes sink down, and, as it were, follow the nervous substance in its retreat. The diminution of the cranium now alluded to may be partial or general, when the atrophy of the brain is general and complete; when the want of development in the osseous parietes of the skull is carried to a very great degree, and is accompanied by a general absence of the brain; in a word, when we find no trace of nervous pulp where the brain should be, the malformation has received the name of anencephaly; this is the highest degree of cerebral atrophy. The volume of the head is reduced to the smallest dimensions, or, rather, no remnant of the cranium exists to show that its development had ever begun. However, we cannot now occupy ourselves with this lesion, which belongs more properly to the history of monstrosities.

In a certain number of cases, where the volume of the brain has been considerably diminished, or even the organ is completely wanting, the cranium, instead of following the diminution of the cerebral matter, retains its ordinary dimensions, or acquires an unusual volume, and becomes developed much beyond the normal standard. Here the bones are hypertrophied; they are more solid, more massive, more thick, than is natural; or, on the contrary, preserving their soft and membranous condition, they yield easily to the distending force of the serum which is shed between the membranes of the brain, and accommodate themselves to the increased bulk of the matters contained within their cavity. In this condition, the brain, and its osseous parietes, frequently attain a great volume, and are designated by the name of

Chronic Hydrocephalus.

We do not mean to assert, in an exclusive manner, that, in all cases of chronic hydrocephalus, the absence of the brain, and the development in the cranial case which accompanies this absence of the nervous mass, is always an effect of some original malformation in the brain; it may, and in fact does, sometimes depend on various diseases of the membranous envelope, as

inflammation, increased secreting activity, &c.; however, in some cases, the atrophy of the nervous substance, with increased bulk of the head, does really depend on an original error of nutrition.

Finally, in some cases that are not very unfrequent, the membranous parietes which supply the place of a bony envelope, open; the cerebral substance, unsupported by its usual protecting boundaries, escapes from the cavity, and forms a

Cerebral Hernia

externally; or a membranous pouch filled with serum, and bearing more or less resemblance to a cyst, projects through the deficiency in the cranium.

In the few observations which we have now laid before you, we have not attempted to give anything like a complete history of the different lesions observed in cases of anencephaly, of acephaly, or other malformations of the cerebral mass connected with atrophy. Our object has been merely to touch in a general manner on the relation which exists between these different states, and a default of development in the brain and its osseous parietes. They were also necessary to explain the numerous and considerable lesions which we sometimes observe in the parts, whether membranous or bony, that surround an imperfectly developed brain. Let us now turn to a consideration of the

Causes of Atrophy of the Nervous Centres.

These are not always the same. Some of them depend upon the non-accomplishment of certain acts or formations that should have taken place during intra-uterine existence.

One of the most beautiful results of the researches which have been made within latter years to determine the mode of formation of animal bodies is the discovery of this curious law, "that most of our organs pass through a series of successive revolutions, each of which represents a normal and permanent organization in inferior animals." The operation of this law is seen in the brain as well as in other organs. Hence at any period when the centre of the nervous system is not yet completely formed, and an arrest of development takes place, implicating either the whole organ or any particular portion of it, we may observe the different types of atrophy which we described a few moments ago, the lesion being more complete as the developmental *nisus* is arrested at a more early period, and in different parts of the brain at the same time. Here then is the first cause of atrophy of the nervous centres; it consists simply in a modification of nutrition, in an arrest of the "*nisus formativus*;" but why this arrest should take place at one period of fetal life rather than another; why it should attack one por-

tion of the nervous centres, leaving others that are contemporaneously developed, intact; these are questions that we are unable to resolve. We can only indicate the arrest of development, without being able to mount beyond it. It is worth of remark that in fetuses born with more or less atrophy of the nervous centres we frequently observe at the same time a deficiency of several other organs showing that the lesion of the brain really depends in an arrest of its development; thus the heart is formed in imitation of the batrachia; the lungs are absent, and the digestive tube presents more or less resemblance to the simple alimentary canal of lower animals.

Again, imperfect development of the brain may depend on various maladies of the membranes which envelop the nervous substance, and by which, according to some physiologists, the nervous pulp itself is secreted. We can understand readily how this may take place, by supposing that the membranes draw towards themselves an unusual share of nutrition, or by a too great activity of secretion prevent the development of the more solid parts. This latter is a powerful cause of arrest of development in several organs contained in the cavities of the chest and abdomen, and may certainly operate also in modifying the nutrition of the cerebral mass. When the absence of a normal degree of development depends upon some disease of the brain, or on inflammation of the pia mater, or irritation of the cellular tissue that every where supports the pulp, the brain may present a general change of form rather than an absence of any considerable portion of its substance. Thus in the latter set of cases alluded to, where the cavity of the cranium contains an unusual quantity of serous secretion, all the different parts, whose ensemble constitute the cerebral hemispheres, have been found to exist. The hemispheres are as it were unfolded; the convolutions are separated from one another and spread out into a vast layer of medullary tissue, resembling a membrane, but on close examination, we find that the nervous substance remains intact in the midst of changes apparently so profound. There is a modification of form only, but no actual diminution, no atrophy of the mass. This has been frequently seen by Dr. CHASSAIGNAC, who has paid particular attention to the changes that take place in the arrangement of the nervous substance during the progress of chronic hydrocephalus.

There is another Species of Atrophy

of the nervous centres which we must not neglect to mention. Here the brain is very small, very small indeed, but it is normally constituted; all the parts exist in a state of perfect integrity. We find the hemispheres, the corpora striata, the central parts, such

as the septum lucidum, the corpus callosum, and the fornix, the optic thalami, in a word, all the component portions of the brain, are found, but they exist as it were in miniature. The organ has suffered from a general arrest of development, acting equally upon all parts, and giving rise to an excessive smallness of the whole mass, without any malformation of a single part.

We have now touched upon a great order of causes which produce atrophy of the cerebral hemispheres, viz., disease or irritation of the membranes, and we are the more induced to admit the operation of this cause when we reflect that in a great number of cases the meninges are injected, thickened, contain abnormal deposits, and present more or less trace of antecedent disease.

Cerebral Atrophy from Accidental Productions in the Brain.

Certain atrophies of the nervous centres depend on a different order of causes. Thus suppose a tumour developed in the anterior of the skull: this must necessarily exercise a greater or less degree of mechanical compression; and the convolutions thus pressed upon, are sometimes completely removed, or at least reduced in bulk and volume. In other cases these accidental productions, instead of acting in a mechanical manner, seem to occasion atrophy of the cerebral substance by exciting a certain degree of irritation in the parts with which they are in contact. Hyperemia is the first result, and when once the nutritive *vies* is deranged, a state of atrophy may succeed this deviation of nutrition, as well as a state of hypertrophy. This is a curious fact, though a certain one, that irritation gives rise to diminution of volume in the part which is the seat of excitement. We have had occasion to observe a remarkable case of this latter kind in the person of a man twenty-eight years of age; who at the age of three fell on his head into the street from a first-story window. The accident was soon followed by paralysis on the left side of the body. The intellectual and other faculties, however, remained intact. This individual died of an inflammatory affection of the abdomen, and on examining the body after death we found that all the middle portions of both hemispheres situated above the lateral ventricles were completely gone; nothing remained of these parts except a vast cavity filled with limpid serum. Here the lesion supervened on external violence giving rise at the commencement to irritation, probably inflammation of the membranes, and subsequently to extensive atrophy of the hemispheres.

Finally, various diseases of the brain may determine an atrophy of the nervous substance immediately surrounding the affected part of the organ. Thus some observations seem to establish that the part of the brain

which surrounds an apoplectic cell may in the end become atrophied. At least it is certain that in individuals who die before their death had presented all the symptoms of cerebral hemorrhage, a portion of the brain, and particularly the corpora striata and thalami (parts, by-the-by, not frequently subject to effusion), has often been found much diminished in volume, and transformed into a species of serous cavity.

We have now exposed at some length the anatomical characters of atrophy of the nervous centres. We have laid before you a history of the lesions observed in the osseous parietes, and in the membranes enclosing the brain. It remains for us only to add, that in some cases we are unable to discover any cause which has given rise to the diminution of volume in the brain. Here we may be permitted to ask, Is the default of nutrition connected with a want of due exercise of the intellectual faculties? A muscle condemned to constant inaction wastes away. May it not be the same for the organs of intelligence? This is not improbable.

The lesion which we have designated under the term "atrophy," does not present itself with the same frequency in all parts of the nervous centres. It becomes more rare as we pass from above downwards, from the surface of the brain to the more deep-seated parts; and it may be established as a general rule that it exists less frequently in those parts of the cerebro-spinal axis which are first developed, than in the portions which arrive more slowly at their perfect degree of organization. Thus atrophy of the spinal marrow is more rare than atrophy of the brain, and, again, in the cavity of the cranium, the deep-seated parts, which are first formed, are less frequently the seat of this lesion than the convolutions. We now propose to pass in review the various degrees of atrophy of the nervous centres according to the different points in which they have been specially observed. We shall follow their order of frequency, and trace their history, in the cerebral hemispheres; in the deep-seated parts; in the annular protuberance (*pons*); in the cerebellum; and, finally, in the spinal marrow. And first for

The Anatomy of Atrophy of the Cerebrum.

Here the lesion may present a great number of degrees, from a slight diminution of the normal volume, to the complete disappearance of the organ. Let us commence with the most severe cases. A certain number of examples have been recorded in which the whole mass of the cerebrum was entirely wanting: there was no brain whatever: and in these cases it is at the same time proved that extra-uterine existence is impossible; or at most possible only for a few short days. The unfortu-

nate beings subject to this degree of malformation, seem made to live only in their mother's womb, and as they are rendered incapable by their organization, of thinking, feeling, or performing at a future time any single act of animal life, so they are incapable of an independent existence, and after a few hours of vegetation lay aside life, which is incompatible with the absence of so large a portion of the nervous centres. This is the highest degree of atrophy of the brain. In place of that organ we find nothing but a slight trace of medullary lamellæ, which afterwards form the brain in a normal condition; or the nervous substance is supplied by a secretion of serous fluid, or by a mass of vasculo-cellular tissue, the rudiment of that membrane which is destined to surround and support the different parts of the interior of the brain. We have already spoken of the condition of the bones in this state; sometimes they are flattened down upon the base of the cranium; sometimes we do not find any trace of conformation of a skull; the parietes are membranous, and contain here and there irregular spots of ossification.

In other cases, as we have already mentioned, the destruction or absence of the cerebral mass is not indicated by any external symptoms. Thus BÉCLAUD has cited the case of a child who lived five days; the cranium was well formed, but it contained no brain; the whole of the cerebrum and cerebellum was absent, and their place supplied by a great quantity of serous fluid contained in the membranes; the spinal marrow however was not absent; this portion of the cerebro-spinal axis had attained its normal degree of development, and terminated superiorly in two bodies corresponding with the cerebral peduncles (*crura cerebri*), each of which again terminated in a kind of *conformation*, or swelling of the nervous substance; two small chords were observed detached from these bulbs, which ran forwards towards the ethmoid bone, became engaged in the groove of the ethmoidal plate, and, finally, terminated in an oblong swelling, exactly analogous to the bulb of the olfactory nerves: here an arrest of development produced in man a disposition of the brain peculiar to certain animals, which, you know, are furnished with olfactory lobes placed in front of the cerebral ones, and destined solely for the production of a single pair of nerves, the olfactory.

The history of the symptoms connected with this form of cerebral atrophy is not long; indeed, it is unnecessary to enter on it. We have seen that this child is, from the instant of birth, condemned to a premature grave; it may enjoy an imperfect life for a few short days, but death is an inevitable consequence of this malformation.

Next, to complete absence of the whole cerebral mass, we may arrange cases where

one or both hemispheres are wanting, and here also the individual is incapable of independent existence. We must distinguish these two cases from those where, in consequence of imperfect development of the superior masses of the hemispheres, we might be led to imagine that the brain was wanting altogether. In the former we now allude to, there is an absence only of the parts which are situated above the level of the ventricles; when the malformation or atrophy is thus confined, when the important parts comprised in the cerebral mass placed beneath the level of the lateral ventricles are sufficiently developed, then a great fact comes to light—viz., the possibility of extraterine existence. In

Atrophy of the Nervous Substance placed above the Level of the Lateral Ventricles,

we may observe two degrees. In one, the atrophy exists at one side of the brain alone; in the second, it has implicated both hemispheres at the same time. Sometimes the whole of this superior portion of the brain is replaced by a membranous bag containing serous fluid; at others, the lateral ventricles are laid bare, and without any dissection we see the thalami corpora striata &c. This case, as we have already observed, does not necessarily compromise life; the individual may continue to live for several years, but all his faculties and senses are obtuse, many of them annihilated, and he lives in a state of vegetation rather than of humanity. When the absence of the substance is less considerable, and confined to one side of the brain, life, as you may conceive, is carried on more, much more, perfectly. This degree of atrophy has often been observed in persons arrived at an adult age. It is compatible with a perfect integrity of organic life, but the intellect is generally obtuse, dull, or idiotic. However, cases of an opposite kind have been seen, and it is remarkable to observe how the intellect may sometimes be conserved with a very great absence of the substance of the brain. M. BRESCHET has published a curious case relative to a child, four years old, where the intellectual faculties were much altered; the infant was plunged in a complete state of idiocy; but what we notice this fact for is to point out the occurrence of mutism. The child was dumb, although not deaf. In all the other cases observed, we do not find mention made of a similar phenomenon. Again, in a great majority of cases we have hemiplegia: the power of motion is lost in one side of the body, although the nervous mass lying below the level of the lateral ventricles exists in a perfect state of integrity.

We now pass to an examination of those more severe cases where the substance of the brain below the ventricles is more or less atrophied. Here we have to consider the lesion as it may occur in the anterior lobe,

in the middle, or in the posterior lobe. We may remark that the anterior lobes are wanting more frequently than either of the two others, and this atrophy may affect either one of the anterior lobes alone or both together. When both anterior lobes are absent together, we generally find the cranium deformed at the same time: it is flattened in the forward part, and the forehead more or less gone. However, some cases of the kind we now speak of, may exist with an excellent conformation of the forehead. Here the cerebral mass which is secreting is supplied by a quantity of serous effusion, or by membranous cysts filled with a clear fluid. What are the symptoms that accompany this

Absence of the Anterior Cerebral Lobes?

How are the great functions affected? Is the intelligence modified? How far? What lesions of motility does it produce? These are questions that we must now endeavour to resolve.

The intellectual faculties are generally modified in a considerable manner, or sometimes completely abolished. Thus M. BRESCHET has recorded a case in the *Repertoire d'Anatomie*, of a girl, 15 years of age, in whom both anterior lobes of the brain were supplied by a membranous cyst, at the bottom of, and behind which, the corpora striata were seen distinctly exposed. This child was a complete idiot; she could not clothe herself, required to be fed, and remained constantly in the same position without taking any notice of what passed around her. What symptoms do we observe in connection with movement? In some cases motility does not undergo any modification, although both the anterior lobes of the cerebrum are simultaneously wanting. This took place for example in the person of the idiot child just mentioned: her listlessness and constant rest did not depend on paralysis or feebleness of the muscular power, but on an absence of volition. The same phenomenon, viz., absence of paralysis may also be seen in two other cases published by M. BRESCHET: in other cases we observe nothing but a general feebleness of the limbs, and this gradually increases until the patient at length falls into a state of paralysis, being unable to move either his upper or lower extremities.

In one of M. BRESCHET's cases there was an abolition of vision. The child, nineteen months old, was perfectly blind, yet we cannot see any connection between the anterior lobes of the brain and the faculty of vision. We cannot understand why an absence of these parts should bring with it complete cecity. The truth is, the more we see of diseases of the nervous system, the further we advance in the study of their history, the more knowledge we attain upon the complex point of medical science, and so

much the more are we convinced of this fact, that the different acts of the brain are connected together as intimately and as closely as are the different anatomical parts by a continuity of organization; and so the more do we feel the necessity of studying in the nervous system, first, its detailed acts, and secondly, its action of *ensemble*.

In another case of absence of the anterior lobes, we find loss of the sense of smelling: this phenomenon is readily explained, and need not arrest our attention. The olfactory nerves are attached to the anterior lobes. When the latter are wanting, it is quite natural to find an absence of the power of smelling. Now for the cases

Where only One Anterior Lobe is Absent,

the other presenting its normal degree of development. Here the brain does not seem to have any great influence on the intelligence; it is ordinarily developed in a moderate degree. The individuals, though not, perhaps, remarkable for talent &c., possess a common share of judgment, good sense, and knowledge of society. In some cases, however, the intellectual faculties are modified; the individual is far from being an idiot, but his mental power is evidently diminished; the intelligence is dull, slow, weaker than natural. In most of these cases of atrophy of a single lobe, we observe hemiplegia, and we draw the same deduction for these that we have done for cerebral hemorrhage, viz., that the paralysis almost constantly occupies the side of the body opposite the injured hemisphere. In one case, which is recorded in the fifth volume of our *Clinique*, p. 620, the patient, a man, seventy-one years of age, in addition to complete paralysis of the left side of the body, was affected with an extraordinary difficulty of speaking, or rather of articulating; he could only utter a few unintelligible sounds. After death we found the anterior quarter of the left hemisphere replaced by a transparent cyst, containing a limpid serosity. This, you may remark, is in accordance with the observations of M. BOUILLAUD, who attributes the power of co-ordinating language to the anterior lobes of the cerebrum. Examples of atrophy, or even of complete

Absence, of the Middle Lobe,

below the ventricles, have also been observed. These cases were accompanied, like the former, with hemiplegia of the opposite side, and the intelligence presented the same modifications as those which we have just mentioned. The same remark applies to atrophy of

The Posterior Cerebral Lobe.

The symptoms do not differ in any point worth noticing from the former cases; we shall, therefore, content ourselves with sim-

ply mentioning the fact. In one case we observed an absence of the middle and posterior lobes of the hemisphere at the same time. It occurred in the person of a man twenty-eight years of age, whose case we have already spoken of at the commencement of this lecture. The middle and posterior lobes on the right side were completely gone; nothing remained but the membranes floating in a clear liquid, and a portion of the anterior lobe situate in front of the corpus striatum. Here was absence of a very considerable portion of the cerebral substance: yet, notwithstanding, the individual enjoyed a common share of intelligence; his memory was good; he spoke freely and easily. Up to the day of his death he never presented any symptoms of disorder of the mental faculties.

You are all acquainted with the position and form of a cavity which anatomists have called the

Posterior Horn of the Ventricles.

Dr. HASTINGS has described two cases of atrophy of this portion of the hemispheres: you will find them detailed in the 59th volume of the *Bibliothèque Médicale*. CUVIER has established, that this posterior horn of the lateral ventricles is very much developed in the brain of man, while it is much smaller, and sometimes quite a rudiment, in inferior animals. We are totally unacquainted with the part it plays in the manifestation of such or such faculty; we shall only remark, as connected with CUVIER's observation, that in the two cases alluded to, there existed a lesion of the grand characteristic which distinguishes man from animals,—intelligence.

In all the cases of cerebral atrophy which we have hitherto passed in review, certain parts of the hemispheres were absent; there was a real loss of substance: the brain did not present the *ensemble* of all those parts which constitute it in the normal state. But atrophy may present itself under another point of view. Here we do not find an actual absence of any part of the brain; there is a general

Diminution in the number of the Molecules of the Brain.

The brain is well formed, but much smaller than in the normal state. This diminution of volume, affecting the cerebral substance without changing its organization, may occupy a single hemisphere alone, a single lobe, a portion of a lobe, or exist on both sides at the same time. An example of this latter kind, published by Dr. CALMEIL, is, perhaps, the most remarkable we have on record. (See *Journal Hebdomadaire de Médecine*, t. 1, p. 225.) All the parts composing the cerebral hemispheres were imperfectly developed, and equally so on both sides,

and the patient was epileptic. No other lesion of any kind or intelligence existed. About two years after intelligence existed. This is a fact worthy of your attention; it cannot fail recalling to your minds what we said in an early part of our course, where we showed that a variety of lesions often coexist with the same symptom, while the nervous system is in question. Thus in our last lecture we noticed a case of epilepsy produced by induration of the cerebral substance. Here you see the same symptom manifesting itself as a consequence of atrophy; the organic lesions differ widely from one another; the functional symptom to which they give rise is the same. The form of atrophy of which we speak, may be circumscribed by a few convolutions; in that case we often find them hard and compact, and wrinkled on the surface like a cicatrix. Instead of the convolutions, the atrophy may occupy the more deep-seated parts, viz., the optic thalami, and the corpora striata. These two elevations may be either simply diminished in volume, without any change of structure, or the atrophy may engage more particularly the gray or the white substance which enters into their composition. In some cases we find not a diminution, but a complete

Absence of the Thalami and Corpora Striata.

They are replaced by a serous cyst, or we may simply observe their absence without finding anything in their place. When these bodies are simply diminished in volume, the hemispheres may or may not be wanting; but when the thalami and striated bodies are absent, we constantly find at the same time an absence of all the nervous substance placed above them. We find nothing but a membranous tissue, and a few scattered filaments. The brain represents the condition in which it existed at a very early period of fetal life; it represents the normal type of the cerebellum in a certain class of organized beings.

Atrophy of these parts, whether general or occupying only one side of the brain, has been observed at all

Periods of Life.

from infancy to the most advanced old age. Sometimes the cranium is depressed upon the portion of the brain seated beneath the absent parts. Here the lesion is discoverable during life, and we have a state exactly opposite to that form of hypertrophy where the osseous parietes seem to be pushed forwards by the development of the brain.

The different modifications of intelligence that we have already pointed out, have existed in individuals affected with atrophy of the thalami and corpora striata, and whenever the diminution of volume has been at all extensive, we have paralysis of the opposite side of the body.

The White anterior lobe. We much the more are we convinced of this fact, that the different acts of the brain are various examples of atrophy. They may be diminished in volume or be absent, without any lesion of the rest of the hemispheres. In a few cases atrophy of the septum lucidum has been observed. In others the want of development affects more particularly the corpus callosum, and this mass of cerebral matter is reduced to the form of a fine membrane. REIL has left us a remarkable example of this latter kind, in the person of an idiot, thirty years of age, in whom the corpus callosum was completely gone, and the two hemispheres of the brain merely united by the anterior and posterior commissures. This is another example where an arrest of development in man gives rise to a form of structure that is peculiar to animals. Thus, in birds and reptiles neither the septum lucidum nor the corpus callosum normally exists. You will also find some curious cases of atrophy of the central parts, detailed in the thesis of M. BOULANGER, No. 195, for the year 1821. In two of these cases there was complete absence of the corpus callosum, and in one the septum lucidum also did not exist. The patients were both idiotic, and one was unable to walk, or sustain herself on her limbs.

Atrophy of the Pineal Gland.

Before we conclude, let us say a word on atrophy of another part, whose use is not yet established, although it exists constantly in the four classes of vertebrated animals. The pineal gland presents a great number of variations in volume: in some cases it is excessively small, not larger than a grain of millet-seed. In others it is so far reduced, that we may in effect consider it as wanting. These varieties in the bulk of the pineal gland do not bring with them necessarily any modification of development in the other parts of the brain, and we are not aware that they are attended with any appreciable symptom. Some writers, indeed, have attempted to connect atrophy of the pineal gland with a diminution of the intellectual faculty, but this is a theory unsupported by a single fact, a supposition in which we can place no belief whatever. We shall continue this subject in our next lecture.

CLINICAL LECTURES

ON CASES OF

DISEASE OF THE URINARY ORGANS.

Delivered in the Session of 1836,

BY MR. LISTON.

LECTURE II.

(Concluded.)

Catheterism in Cases of Stricture.

Now I would have you follow, in these cases of bad stricture, the practice I have detailed, such practice as, in fact, we have pursued in the several cases I have brought in review before you. You should try to get an instrument into the bladder. It is all the same whether it be large or small. Tie it in; and it is better to begin with a metal catheter, such as this, at once, than to be poking away with these wax catheters, elastic bougies, and bits of fiddle-string. What can you expect by trying to put such a thing as that (it is called a catgut bougie, I think) into the bladder? It is better to work with an instrument with which you are sure to succeed. You are recommended by Sir BENJAMIN BRODIE, a great authority in these matters, in this book of his, to try first all sorts of things, gum catheters, catgut bougies, &c. &c.; then you are to bend your bougie after this, that, and the other fashions, and if you fail notwithstanding, you are at last to have recourse to the silver catheter. Why, the mischief, should you not take the silver catheter at once and pass it into the bladder?

Well, you introduce the catheter, and how does it act? Why, in the first place it is grasped and held firmly by the stricture, so that the patient or the surgeon would find very great difficulty in withdrawing it. But after a little time the parts become impatient at the presence of this foreign body, and a natural process is set up for its discharge. It is exactly the same process as that which takes place to favour the escape or ejection of a foreign body lodged in any part of the living tissues. There is a profuse discharge from the surface of the urethra, and the parts all become widened and relaxed; and unless the catheter were tied in properly, it would tumble out. In the course of twenty-four hours, part of the water comes to be discharged by the side of the tube. The next day you find the instrument still looser, and the discharge more profuse. You then cut the tapes with which the catheter is tied, and can pass a larger one without any difficulty. Then allow the

ply mentioning the fact. In one case we observed an absence of the middle and posterior lobes of the urethra, and the mercury did not ascend to see that time. If it is right, and then make the intervals of introducing the instrument much longer. Pass one at the end of four or five days, and thus proceed until you have brought the canal to its natural state. I would not have you retain these catheters longer than forty-eight hours, or three days at all events, otherwise a great deal of mischief will arise. You find, if it is kept in very long, that the further end of it, the eyes, become coated over with earthy matter, and, in withdrawing it, portions of that earthy matter have sometimes been separated, and a nucleus for a calculus has been formed in the bladder. Another mischief which I have seen to result occasionally, is the formation of abscess in the canal, and, frequently, anteriorly to the scrotum. A false passage is the consequence, and it is very difficult to get an opening in this part of the canal to heal up. It has been proposed in what are termed "impassable strictures,"—but there are no strictures impassable, that I have seen, for when any water comes away, you can, by patience and perseverance, get a catheter through, sooner or later,—it has been proposed to introduce either an elastic gum catheter, as recommended by DEPUYRÈS, or a silver catheter, down to the stricture, and to keep it pressed against it, in contact with the obstacle; and it is said that in general, after a little time, the catheter will slip of itself into the bladder. I have seen this tried, but I cannot say that I ever witnessed any good result from it. I should think, that if a catheter will slip through in this sort of way, the surgeon would be able without much difficulty to introduce it. Here are two of the last works on this subject, one by a St. George's Hospital, the other by a Westminster Hospital surgeon. I have derived from them a great deal of satisfaction. There is a case related in the work of the latter gentleman which has amused me not a little. The method of securing the catheter is detailed, but I would recommend you to follow the mode you see adopted in this hospital, merely fastening a tape to each of the rings of the catheter, bringing them under the thighs, and then tying them to a handkerchief round the waist. There is no necessity for bandaging up the penis, and putting rings on it, and tying it up in lint and bobbin, as is sometimes done. In the case related in the book, an instrument, a gum elastic catheter, was put down to, and kept in contact with, the stricture. The patient was kept very quiet, and "the catheter kept going a little further in," for eighteen days, without its being passed through the stricture, though all that time the patient was making water by the side of the instrument. What it was

and the patient at all this while I cannot say. About two or three such is the happy commencement of the practice. After a time they did succeed in getting an instrument into the bladder, and after that, in order to make up for lost time, I presume, they went on passing instruments every day, a practice which I have already reprobated as producing great inconvenience and suffering to the patient, and as not exactly the way to restore the parts to their natural state,—certainly not the way to tranquilize them; although Sir EVERARD HOME, after the four hundred and eighty-nine applications of his caustics, thought it necessary that the patient should have a bougie put in to keep the parts quiet and tranquil.

Cases of Stricture requiring the Employment of the Knife.

Now, sometimes you will not succeed in passing a catheter into the bladder, and you cannot expect to succeed where the passage is completely closed. Cases of that kind are now and then met with,—cases resulting from injury, or from violent inflammatory action, followed by the formation of matter, loss of substance, sloughing, and so on, in the perineum. In such cases it may be necessary to cut down into the passage, and to carry the knife forwards into the stricture, until you meet with the catheter passed down the sound part of the canal from before. This can only be required where the water flows through fistulous tracts, and none whatever is passed through the natural canal for a considerable time. I have, however, already stated, and proved by cases, that you may sometimes succeed in introducing a catheter when no water has passed for some time. I succeeded in one case where the patient had made no water by the urethra for fifteen months; but where the passage is completely obliterated, where it is closed, and closed from violent inflammatory action, (the result, say, of injury,) while the cellular tissue all around is glued up, and there is, perhaps, an extensive deposit and organization of new matter,—in such case you must resort to cutting instruments. I have been obliged to have recourse to these operations in a few cases. One was that of a boy, about fifteen years of age, who had had his urethra cut across. He was engaged in the Carron foundry, and being about some mischief or other, was pursued by one of the workmen, when he jumped out of a window, and alighted on a bar of iron, which stood upright in the ground, in consequence of which he received a wound of the perineum, and had the urethra, it would appear, cut clean across. He was brought to me a long time afterwards, passing his water entirely through openings in the perineum. As there was no possibility of passing an instrument, however small, it became necessary to make an

incision into the raphe so as to expose the orifice, to lodge the instrument in the urethra, for a time. I had occasion to pursue this plan, also, in the case of a very dreadful stricture, followed by abscess of the perineum,—a stricture resulting from a bruise of the perineum, in consequence of the man's falling from a great height on a beam of wood many years previously. All attempts to reach the bladder failed; the water was passed with difficulty, and with great straining, altogether, as it has been for many months, through various openings in the perineum. The urine was mixed with muco-purulent stuff. There was reason to suspect disease of the kidneys, in addition to the abnormal state of the bladder and its outlet. Under these circumstances, incision was resorted to for the re-establishment of the passage. In another patient, also, who positively declared he had not made any water through his urethra for about fifteen years, incision was had recourse to. He had been under treatment for stricture, had come to this city, and had had a caustic bougie introduced, rather roughly he thought (by no means an unfrequent source of complaint). This was followed by profuse hemorrhage. On riding down to Woolwich immediately thereafter, his horse shyed, and in addition to the injury inflicted by the surgeon inside of the passage, he got a severe bruise outwardly by striking his perineum on the pommel of the saddle. In consequence of these injuries, abscess and sloughing took place, and, in the end, the whole of the water was passed through the openings in the perineum I have mentioned. I am astonished that he should have submitted to this so long, for he was in the prime of life. I should think that he was not much over fifty years of age when he applied to me. When I first saw him, he passed his water through the perineal openings with difficulty, frequently, in small quantities. It was mixed with much ropy mucus, furnished by the thickened congested lining membrane of the bladder, no doubt. The bladder must have been very much diminished in capacity, the muscular coat being also thickened. He had great and frequent straining to make water. It was necessary to enlarge this artificial opening, the patient being secured in the position for lithotomy. I passed a catheter down into the perineum, near to the sinus of the urethra; not quite so far, but about four inches down; and on making an incision into the perineum, I cut forwards upon the point of the catheter, and readily carried it on to the bladder; the result was, that the whole of his water came through the natural passage, and he enjoyed himself after a short time, I suppose, just as much as he did before his mishap.

Now in making these incisions, you are not

greatly assisted in catching the point of the canal. If you cut upon an inextensible stricture, you know that the canal is greatly enlarged behind; and if you cut in the middle line, from near the apex of the prostate, the finger being placed in the bowel as a guide, directing the point of your knife upwards and forwards, you must hit the passage, and you are not interfered with by vessels. There is no hemorrhage; very little, at any rate. You can make an extensive incision, from the verge of the anus, into the perineum, and there is no difficulty in cutting into the anterior part of the passage. It is only in those cases where no water comes through the passage at all that you are warranted in cutting down, for, in general, by proper study of the parts, and by considering well the nature of the disease, and practising on all occasions the introduction of the silver catheter, you will attain such dexterity in its use, that you will have small difficulty, in almost every instance, whatever the case may be, in getting an instrument into the bladder.

Rupture of the Bladder from Retention.

In retention of urine there are very considerable peculiarities as regards the state of the bladder and the state of the urethra. In strictures the bladder is generally diminished in capacity, as I have before said. It contains but a very small quantity of urine; it can bear distention to a very slight extent, without occasioning unpleasant or uneasy feelings, and without great risk occurring if the viscus be not relieved; but this is not the case in all instances of retention. In some, the bladder is capable of containing two or three pints of water, and it rises up into the cavity of the abdomen exactly as the gravid uterus does, forming a large oval tumour in the "lower part of the stomach," as the ladies and their doctors call it. The belly is swelled, if I may use that phrase. There is a large oval swelling in the lower part of the abdomen. Now in some of those cases there is a much greater chance of the parts giving way, and an infiltration of urine taking place into the cellular tissue, than there is in others. In retention from stricture, more especially where an abscess has been in progress beforehand, there is a greater chance of the cavity of the abscess communicating with the urethra, the parietes of the urethra bursting, and the urine escaping into the cellular tissue, than of the urethra behind the stricture yielding. The risk in such cases is very great indeed, but the risk of infiltration from retention of urine is greater. In retention from obstruction at the neck of the bladder, from enlargement of the prostate gland, impaction of stone, or other cause, the urine is extravasated,

ply mentioning the fact. In one case we observed an absence of the middle and posterior lobes of the prostate, and the beginning time, into the pelvic cavity. When it takes place, there is little or no chance of the patient's recovering, whereas when it arises from the giving way of the posterior part of the urethra, though the danger is great, yet recoveries often are made, even after the loss of much integument and cellular tissue, the covering of the testicles &c. In cases of

Retention from Injury of the Perineum,

you will in the first instance endeavour to pass an instrument into the bladder, so as to empty it for a time, until the parts have recovered in some measure from the effects of the injury. At a later period, when there is great swelling and some effusion of blood, more especially if the patient have strained to make water, you will have to make a free incision into the perineum, in order to allow the escape of the blood and water, mixed up together. At the same time it is sometimes though rarely necessary to pass an instrument through the lacerated urethra into the bladder. You may in some of these cases be under the necessity of puncturing the bladder. This has been called one of the regular operations of surgery, but it is such an operation as you will very seldom see performed here. Where there is no previous contraction, but where the retention arises from inflammation of the parts, you will be able to relieve the patient, without the employment of instruments at all, by warm-baths, and the exhibition of opium, with the addition of an opiate suppository. If the patient be not thus relieved, you must at all risks introduce a catheter into the bladder, and if there have been no previous contraction, there should be no difficulty in effecting your object. Again, in

Retention from Stricture,

which is the most difficult to manage of all, there is no faith to be put in opium, the tincture of muriated iron, or anything of that kind. There is then no time to be lost. Have recourse to the catheter at once. The parts are altered, and there is very great probability of the urethra suddenly giving way, not bursting, as people say in books, but sloughing, and of extravasation of urine loaded with saline matter, taking place into the cellular tissue. It is not very common for patients to recover from this, though they do recover now and then. You must introduce the catheter and retain it, because you may find a difficulty, if you withdraw the catheter, in getting it replaced, for the patient may be subject again to retention, so that you will be under the necessity of introducing and re-introducing the catheter; but if you do away with the chance

and the patient's recovery, you will be towards the cure of the stricture. There is a case related in one of the hospital journals in which this practice was pursued,—a case of very bad stricture, occurring in a patient, I think, of Mr. COOPER. He did not see the patient, as I think he was then out of town, but I happened to come to the hospital at the time, and found that the house surgeon had been foiled in passing the catheter. The patient, it is here stated, had been affected by gonorrhoea three years previous to this attack, and he had never been altogether free from discharge. He more than once had laboured under retention, from which he was easily relieved. However, the stricture had been getting worse and worse, and on this occasion, before his admission, his surgeon had attempted to pass an instrument, without success, and he then sent him here. He had passed no water for twenty-four hours; he had pain and tenderness in the perineum, very likely increased by the attempts which had been made to overcome the stricture. He had been put into the hot-bath, and long and continued attempts had been made to pass the catheter after he had come out of it, but without success. A false passage, it is said in this report, was discovered. He had forty drops of the muriate of morphia given to him, and the following is the report of the house surgeon:—"On Mr. LISTON's coming into the hospital, he was asked to introduce the instrument, and by dint of considerable force,"—that I deny,—and dexterity, he succeeded in passing the catheter." I did not use what may be called "force," though I dare say some little dexterity was required, and after the point of the instrument was lodged in the stricture, which you know by its being held firmly, steady pressure was perseveringly employed. The catheter being passed into the bladder, that viscus was emptied. The instrument was quite loose in two days. On the 6th, two days after it had been introduced, it was withdrawn, and he then made water with but little smarting. On the 14th he was discharged quite cured.

Now when abscess forms in the perineum, more especially

When Extravasation of Urine takes place,

you are called upon immediately to make a free opening into the perineum. Make an opening directly into the collection of matter and urine. As soon as this is done, the necessity for passing an instrument into the bladder has ceased, because the bladder empties itself into the perineum, and the water comes freely through the opening. Besides, if the urine be infiltrated into the cellular tissue of the scrotum or penis, you must make many good free punctures, of about half an inch in length each. It is time enough to pass the catheter

ter into the bladder has gone off, after and the sloughs have come away.

I have said, that in almost every case it is possible to succeed in introducing the catheter; but it may happen that you are not able to do so. You may then be under the necessity, as a last resource, of

Puncturing the Bladder.

I have already stated, that you will seldom see this operation performed here. I have had a pretty extensive practice in these cases both in public and in private, but I have never punctured the bladder yet, and I hope I never shall. You will find the same opinion entertained by other surgeons. Mr. THOMAS BLIZARD, under whom I studied, and no man could be more dexterous in the use of instruments, was decidedly of this opinion. You will find it stated in DESAULT'S works, that he once punctured the bladder, but that was when he had had no great experience in these matters, and when he first took charge of the *Hotel Dieu*; and he expresses his conviction, that if the case had occurred later in his practice, he should have succeeded with the catheter. But if you cannot manage to give succour by the catheter, why then you must puncture the bladder. You must relieve the patient from his sufferings at all hazards, and it would be better to puncture in all the three places at once—above the pubis, in the perineum, and through the rectum—than to allow the patient to suffer from extravasation and destruction of the cellular tissue.

There is only one other species of retention of urine, and that is, from disease at the neck of the viscus, and paralysis of the muscular apparatus of the bladder—from

Enlargement of the Prostate.

In general, in such cases, you can succeed in relieving the patient by the employment of a proper instrument—by a long catheter, such as this,—one at least four or five inches longer than those usually employed, the curve being large and the beak long. There is no use in poking away with shorter catheters, because you cannot by any possibility reach the bladder with them. The urethra is elongated by the enlargement, by the hypertrophied state of the gland; the prostatic portion of the urethra is immensely lengthened; and, besides that, the bladder is generally capacious; it is enlarged to an immense extent; after it has become so far distended and bulged for a time into the hollow of the sacrum, the fundus of it begins to yield, and then the viscus rises into the cavity of the abdomen, and in that way the cavity of the bladder is further removed from you than in the natural state; you require, therefore, a much longer instrument to reach it. I have seen many cases where it was supposed that the blad-

ter; and you have seen the patient's room, instruments of catgut bougies, elastic gum catheters, silver catheters, and bloody. The instruments have come out filled with blood, but that has been from laceration at the neck of the bladder. On introducing such a catheter as this, however, the water has come away naturally; not perfectly transparent, because it is mixed up with mucus of a dark colour. It contains a great quantity of saline matter, and it is in consequence of this change in the quality of the water, when it has been long retained, that such rapid mischief arises on its being discharged into the cellular tissue.

Now there is another cause of retention, and that is, the

Loss of Power in the Bladder

to expel the urine. We had a case showing this very well the other day. The retention was supposed to arise from stricture of the urethra, but my opinion, from the first, was, that it did not arise from that cause. The patient stated, that for a long time he had difficulty in making water, and he attributed it to his having been prevented from time to time from emptying his bladder. He was in the habit of driving out parties of ladies into the country, and he could not very decently get off the box to empty his bladder. Upon several of these occasions he had retained his water much longer than he otherwise would have done, and at last, when he came to pass his water, he found that he did so with difficulty. On this occasion it stopped entirely, and he applied to a surgeon, who introduced a catheter, but did not succeed in getting it into the bladder. When I saw him, the glans penis was swelled considerably, the whole organ was in an excited state, and I should not wonder—he was a man pretty well advanced in life—if he had been straining himself, or over-exerting himself in some venereal encounter, which it is not very safe in old men to attempt to any great extent. However, in consequence, the parts had become inflamed. He at first passed his water pretty well, although, perhaps, he could not empty his bladder entirely, but at last the water stopped altogether. An attempt was made to pass a catheter, as I have already stated, but without success. When the patient was admitted, Mr. WALLIS, my house-surgeon, with some little difficulty, succeeded in getting a small catheter into his bladder, and drew the water off. The catheter was secured in the bladder, under the impression that this was an organic and unyielding stricture, but the patient in his restlessness withdrew it, after it had been in for three or four hours. The consequence was that the urine reaccumu-

ply mentioning the fact. In one case we observed an absence of the middle and posterior lobes of the prostate, the middle lobe being swollen, the glands red, and the discharge coming from the parts. There was no gonorrhoea, but the parts were in a state of excitement, and a slight inflammation of the lining membrane of the passage existed, probably from the cause alluded to, and from the use of the instruments.

I passed a catheter of a pretty large size into the bladder without any difficulty, and I found that there was no such resistance, or grasping, as is met with in cases of bad stricture. The catheter was retained, and in the course of two days a much larger instrument was passed without difficulty. He says he has had symptoms of stricture for twenty years, especially if he caught cold, and from which he had some difficulty in making water. He has had very little surgical assistance until the retention became severe. He is of very temperate habits. On Sunday last he got wet from the rain, and on Monday he passed his water with difficulty. On Wednesday he applied to a medical man, who attempted to introduce a catheter, but without success, and at about seven or eight o'clock, he was brought to the hospital. Number 3 catheter was then passed in, to about an inch from the orifice, and it was supposed that he had a stricture, though I could not find any. Indeed, I think that if there had been, the passage would not have yielded quite so readily. "He was then put into a warm-bath. A little water followed the withdrawal of the catheter. Half a grain of muriate of morphia was then given to him, and fomentations were applied to the region of the bladder. When under the influence of the morphia, a small catheter was passed in, and a great quantity of water was drawn off. The catheter was tied in, but the man became restless, and it came out at 9 a.m. He passed a very good night. Number 4 catheter was put in on the next day, and four pints of water were drawn off."

Now my reason for thinking that there was no stricture, and that the disease was merely a want of power in the coats of the bladder, was that in stricture you very seldom find the bladder so capacious as it was in this case. It is generally contracted, in order to overcome the resistance arising from the stricture. There were four pints of water drawn off here, and in such cases the bladder frequently contains most likely not more than from four to twelve ounces.

I thought it was much more prudent, in this case, to retain the catheter in the bladder. In cases of over-distended bladder, where the canal is sound, the bladder recovers its tone better when the instrument is introduced only as occasion requires, I say twice or thrice in twenty-four hours; but here the difficulty, experienced by the house-surgeon in introducing the catheter,

and the patient's aversion to doing so, and it was thought best to detach the catheter, so that the bladder could be kept empty, and it would thus have an opportunity of recovering its tone. In a short time a full-sized catheter was introduced. The bladder was found capable of relieving itself by full and free stream. The patient was accordingly dismissed cured, after but a very short residence in the hospital.

CASE IN WHICH

GOUTY CONCRETIONS

WERE EXTENSIVELY DEPOSITED IN

VARIOUS PARTS OF THE BODY.

To the Editor of THE LANCET.

SIR,—I beg to transmit the following particulars of an interesting case, which I obtained on seeing the invalid during a late visit in the country, for insertion in your valuable Journal. I am, Sir, your obedient servant,

T. HERBERT BARKER.

North-London Hospital, Feb. 11, 1836.

Mrs. C., ætat. 45, resides at Hemel Hempstead, Herts. She is emaciated, and of sallow complexion. She has never enjoyed very good health. She has had three children, all of which died either at birth, or in early infancy. She has never been accustomed to luxurious living. About fifteen years ago she had an attack of inflammation of the great-toe of the right foot, and of the carpo-phalangeal and phalangeal joints of the middle finger of the right hand, which lasted for some time, and left the parts a little red and swollen. She subsequently had irregular paroxysms, of a similar character, affecting the smaller joints of the hands and feet, and the ankles and heels. About seven years ago, after a severe paroxysm of heat, redness, pain, and swelling, in the joints first affected (those of the right middle finger), she perceived some "chalky matter" deposited in the parts affected, which, previous to its escape, very much aggravated the pain, by breaking the integuments immediately covering it. Since she first perceived the concretions, their formation has been so extensive, that there is scarcely a square inch of the surface of the fingers, the hands, the toes, or the feet, in which they may not be observed, particularly at the metacarpo and metatarso phalangeal, and the phalangeal joints, which are so extensively studded with protuberances of various sizes caused by the concretions, as to cause great deformity. She has had not less than a dozen openings in

the feet, and nearly

hands, from which great quantities of these concretions have escaped. Their formation has always been preceded by most excruciating pain, and the pain has always been relieved by the application of cold, and much aggravated by the application of heat.

Beside the existence of the disease in the joints which have been enumerated during the last six or seven years, the elbows, the shoulders, the knees, the hips, the nose, the cheeks, and the gums, have been the seats of similar pain, heat, redness, and swelling, followed by concretions in the right elbow and knee, and on the left side of the nose.

Her grandmother was a native of Dunstable, and was terribly afflicted with a similar disease. The parents of Mrs. C. were entirely free from the disease. They had never had an attack of gout in their lives. She has been repeatedly told by her friends that the disease was caused by her use of the water of Dunstable, because it was impregnated with saline matter, in consequence of the abundant calcareous strata in that part of the country.

She has been most egregiously neglected, never having had any medical attendance for her very painful malady. A long time ago, some friends recommended the application of Goulard's lotion, which she used once or twice, with temporary relief from the pain, but she desisted from its further employment, the danger of such applications being represented to her by some other friends as being considerable.

She says that nine or ten years ago she had a severe and long illness, with "brain fever," which was caused by insolation; and that, during the last two years, she has scarcely been free for an entire month from erysipelas of the head and face, or of the parts affected in the hands, where it has generally assumed a severe form.

At the present time, there is a protuberance of about the size of a horse-bean, situated just beneath the skin, opposite the inferior margin of the left nasal bone. It is hard and moveable, and the light-coloured concretion, similar to that which is so plentifully distributed over the hands and feet, is seen through the transparent cuticle covering it. The fingers are exceedingly deformed, there being clusters of indurated protuberances at almost all of the phalangeal and metacarpo-phalangeal joints; several masses of similar substance are situated upon the dorsa of the hands, and about the wrist. The white saline matter may be observed underneath the diaphanous epidermis, of various size and figure, in different situations. The mass, situated at the joint between the metacarpal bone and the first phalanx of the left index-finger, is of about the size of a hen's egg,—hot, red, and very painful, with a small but deep ulceration

part of it, which has been discharged a quantity of a rather thin and offensive purulent fluid mixed with the saline matter, and probably holding some portion of it in solution, imparting to the fluid a chalky-white colour. The metacarpo-phalangeal joint of the little-finger of the same hand is of about the size of a walnut, but is not red; neither is it, like most of the other protuberances, painful on pressure even, although it was the seat of excruciating pain at an earlier period of the affection.

The feet are similarly deformed, and the white masses may be seen, as in the hands, covering the toes, heels, sides, and dorsal surfaces.

There are three tubercles of similar concretion, the largest of about the size of a small pea, situated opposite the external condyle of the right humerus. And there is a small concretion deposited on the inner side of the right knee. The pulse is 70, and rather feeble; she has a slight cough, and expectoration in the mornings, in consequence of having caught cold a short time since; the skin is cool and dry, she never perspires excepting during the violent paroxysms of pain, when perspiration and cold shivering frequently come on alternately; and she generally has shiverings and flushes of heat alternate with each other for a short time previous to the attacks of erysipelatous inflammation. The tongue is dry, and covered with a whitish fur; the appetite has always been impaired; she is almost constantly distressed with urgent thirst; the bowels are generally somewhat relaxed; the urine is usually rather small in quantity, and high-coloured, depositing a heavy brown sediment; she has at no time had any difficulty in voiding it. The function of menstruation has usually been pretty regularly performed; at the present time there is some little irregularity, which she attributes to the age at which she has arrived.

Remarks.—Similar cases to the above are not very frequently met with. The concretions usually occur only in one or two of the smaller joints, but here there is scarcely a small joint of the extremities that is not involved, together with one of the knees, one of the elbows, and the nose. The age of this poor woman, too, is rather early for their formation.

It presents an instance of this hereditary disease passing over a generation. Although the patient could not give me much information concerning the case of her grandmother, still she assured me that she was greatly afflicted with it. The parents of the patient lived to a good old age, and were completely free from it. This passing of hereditary affections over alternately

ply mentioning the fact. In one case we observed an absence of the middle and posterior lobes of it in a popular region amongst the inhabitants of places near the chalk hills (which are very numerous in Bedfordshire and some adjoining counties), that this disease is induced by the water of those parts, but we need not resort to such an explanation, since the chemical composition of these concretions, explains the pathological relation which subsists between gout and gravel. Moreover, it would be difficult to explain their peculiar composition from the inhibition of water from a calcareous soil. The only cases, however, which I have seen (three), and one of which I have heard, occurred in persons who belonged to such localities. Dr. Wollaston first demonstrated that the real composition of "chalk zones" was uric acid, combined with ammonia, potash, or soda, generally with the former. It is sometimes combined with lime, and phosphate of lime enters into the composition of some of them. I brought to town with me a few grains of the concretions which have escaped from the hands and feet of this woman; they are in light masses, of a white colour, soft, friable, and intersected abundantly with cellular tissue, insoluble in cold, but slightly soluble in boiling water. On adding to the solution a few drops of nitric acid, and evaporating it to dryness, the beautiful purple colour of the purpurate of ammonia made its appearance, formed by the decomposition of the uric acid, and highly characteristic of its presence. On placing a portion of the concretion upon platinum, and directing a flame by means of the blowpipe upon it, it gave out a strong animal odour, partly depending upon the cellular tissue entering into its formation. On continuing the flame it was apparently destroyed; not a particle remained, proving the absence of phosphate of lime; it did not entirely fly off, proving the whole of the alkaline base not to be ammonia. The surface immediately surrounding the spot on which the concretion was placed, was covered with a small quantity of a fused substance, which was soluble in warm water, and was proved to be distinctly alkaline. It is, then, very probable that the lithic acid in this case was in combination with soda or potash. The woman had not been in the habit of preserving the concretions after their escape, and the quantity that I obtained was so very small, that it was impossible to prove their exact chemical composition. An able chemist has kindly offered to make a quantitative analysis of these concretions when I shall have obtained a sufficient quantity; and probably at a future period I shall be able to publish more satisfactory information on this point.

lesion of in-

TAR IN THE BLOOD.

To the Editor of THE LANCET.

SIR,—A short time ago, while experimenting on the human blood, I separated from it a peculiar species of petroleum, and on referring to the analysis given by several eminent chemists, I found that this principle was not at all noticed by them. I therefore am led to suppose that it has not before been separated from the blood, unless very recently, and published in some work which I have not had an opportunity of seeing.

Process.—One pound of blood was taken from a man about fifty years of age, and before separation took place, it was well mixed with one ounce, by weight, of concentrated sulphuric acid, and stood frequently for twenty-four hours. To this mixture was added two ounces of carbonate of lime, and the whole again was well stirred up till effervescence ceased. A glazed earthenware retort was then procured, having its beak lengthened with a tin tube, about three feet long, the extremity of which was introduced into a quart bottle, and the bulb of the retort into a small sand bath, which was placed in a charcoal furnace. A strong fire was gradually raised, while the beak was kept cold by means of wet cloths. Carbonic acid gas first came over, which was allowed to escape; then a most disagreeable smell was evolved, when it was found necessary to lute the receiver to the retort, to prevent its escape. At length a fluid distilled over, and with it the tar. Some floated on the surface, while some formed into globules and went to the bottom. When the distillation was complete, the tar was separated, by filling the bottle quite full of water, and taking the tar from off the surface by means of a slip of glass.

This is the process which I used for extracting tar from blood. For some time I thought it was an oil, and laid it aside as such; but the laws of chemistry do not allow us to judge of substances simply from their appearance, and further experiments proved to me that the product was decidedly tar, and not oil.

I afterwards repeated the experiment, by acting upon eight pounds of sheep's blood; and using the same proportions of acid and carbonate of lime to each pound. From this I certainly expected to obtain a large quantity of tar, but the retort not being glazed, a portion escaped through the pores. Consequently, I was unable to ascertain in what proportion it existed in the blood, but the quantity thus extracted was one fluid drachm.

Animal tar is adhesive to the touch, and lighter than water, and possesses about the same degree of consistency as common

vegetable tar, but it is very materially improved in smell, and is extremely disagreeable. It is soluble in alcohol, and turns of a thick brownish white colour when mixed well with water. By evaporating the spirit, the tar again floats on the surface. When ignited it burns like common tallow, leaving a smell not unlike that of burnt feathers. The quantity obtained being too small for redistillation, I was obliged to heat a little in a bulb glass to the temperature of ebullition, when a spirit was given off which took fire when brought in contact with a lighted taper.

I hope that my experiments will be repeated, provided the result is yet otherwise unknown; not that I think it of great consequence, but we must always feel interested in seeing the secrets of nature unfolded. Transmitting this account for insertion in your excellent journal, I remain, Sir, your obedient humble servant,

HENRY OSBORN, Chemist.

Southampton, Feb. 16th.

BROWN BREAD.

To the Editor of THE LANCET.

SIR,—Allow me, through the medium of your valuable journal, to call the attention of the profession to the uses and effects of brown bread, both as a remedy in habitual costiveness, and also as an article of diet. I am induced to make these observations, in consequence of having myself experienced both its value as a remedy in the above-mentioned state of the bowels, and its injurious effects when used for any length of time as an article of diet. Its medicinal virtues are really surprising. It scarcely ever fails to remove, in a very short time, that habitual costiveness which so generally accompanies a sedentary life. But when its use is continued for some time after the costive state of the bowels has been removed, its effects are most injurious. It then produces all the symptoms of dyspepsia, and irritation of the whole alimentary canal. The laxative effect arises from the particles of bran which it contains, acting as a mechanical stimulant, and increasing the peristaltic action of the intestines. Now the very manner of its action as a laxative, proves its unfitness as an article of diet; as it is necessary for all substances, in order that they may have any mechanical effect upon the bowels, to possess the power of resisting the action of the gastric juice, and all substances that have this power (for instance the rind of vegetables, under which denomination bran comes) also possess the power of producing great derangement of the alimentary canal, and I believe

continued use of bread containing bran. Brown bread is very extensively used in this city, and is sold under the name of "Constitutional bread," a name which it is not deserving. I will at some future period furnish you with cases illustrative of its effects. Believe me, Sir, your obedient servant,

CHARLES WRIGHT.

Harcourt-street, Dublin,

Feb. 13, 1835.

SYPHILIS.

"A gentleman who had been cured of a chancre at a distance from home, called to consult me whether he might consider himself as perfectly free from the disease. Whilst he was taking great pains to explain to me how he had been salivated, and how long he had continued the use of mercury after the chancre was healed, I interrupted him by observing, that if he had continued the use of mercury till now, I could not pretend to say whether he was free from the disease. 'How then,' said the gentleman, 'am I to ascertain my real situation?' 'If,' replied I, 'you find no symptoms in the course of three months, the probability is that you will remain well till you expose yourself to a new source of infection.' In about six weeks he returned, with a sore throat and copper spots. I explained to him that he should not blame his surgeon, who, even if he had known what was to happen, could not have prevented it. The patient went through a necessary course of mercury, till he was cured of every symptom; and then demanded, with some impatience, whether he was secure. 'You are secure,' replied I, 'from every return on the genitals, and on your skin and throat; but, as it is impossible for me to know whether your bones are contaminated, I cannot pretend to say whether you will have nodes in a few weeks' time.' He now began to comprehend the doctrine, and submitted to await the result. In about six weeks he actually had nodes; after the cure of which, by a severe salivation, I made no scruple to assure him, he was perfectly free from the disease."—*Mr. Hunter's last conversation with Dr. Adams.*

The effects of the venereal poison upon the human body, Mr. Hunter describes under the three different states of "contamination," "disposition," and "action." By *contamination*, he implied the entrance of the poison into, and its contact with, some part of the body. By *disposition*, the intermediate state between contamination and the breaking out of the disease, or the state of *action*.

First, of the state of contamination.

Mr. Hunter was of opinion that mercury, if given immediately before the appearance of chancre, prevents contamination. He says, "If the poison were still capable of circulating after its visible effects were cured, the mercury given in the time of a chancre can be of little service, as it can only assist in the cure of a chancre, but cannot preserve the constitution, which does not agree with experience; for practice informs us, that not one in fifty would escape the lues venerea, if the chancre were only cured locally: so that mercury has the power of preventing a disposition from forming, and therefore is necessary to be given, while we suppose absorption going on, or while there is matter that may be absorbed."—Page 429, second edition, by Dr. Adams.

Dr. Adams, commenting on this opinion, observes,—“This is a fair inference, but its truth can never be ascertained, because the primary diseased action, whether chancre or gonorrhœa, has always commenced before mercury is applied.”—Page 433.

The experience of the military surgeons, especially of Mr. Guthrie and Mr. Rose, although of no very recent date, throws considerable light on this important point. Mr. Guthrie, in an interesting paper, in the *Medico-Chirurgical Transactions*, I believe, vol. viii, observes,—“During the last eighteen months, in the York Hospital, Chelsea, Mr. Dease, Dr. Arthur, Dr. Gordon, and myself, have been in the habit of treating all cases of ulcers on the penis, whatever form or appearance they might have, by simple mild means; that is, by dry lint, or ointment, or lotions, for the most part not containing mercury, in order to obviate the objections that might be made to the application of mercury in any form; and of near one hundred cases which have been treated in this manner, all the ulcers healed without the use of mercury. The primary sores were of every description, from the superficial ulcer of the prepuce and glans, to the raised ulcer of the prepuce, the excavated ulcer of the glans, and the irritable and sloughing ulcer of those parts.

“The secondary symptoms, in the cases alluded to, amounting to one-tenth of the whole, and which were treated on the antiphlogistic plan, have hitherto been nearly confined to the first order of parts—that is, the bones have in two cases only been attacked, and they have equally been cured without mercury.”

“A gentleman, aged 27, contracted venereal sores in the month of June, 1833, and was put under a mercurial course, during which time the sores healed, but he still continued the mercury. While under the influence of that medicine, he indulged in impure connection, the consequence of which was a fresh crop of venereal sores, three or four. The mercurial course was

prolonged until the healing of these second sores. About two months after this, secondary symptoms made their appearance, for which he was again salivated, with apparent success; but now a new enemy appeared in the field, in the shape of rheumatism, and he again applied for medical advice. The surgeon whom he consulted considering it a case of venereal rheumatism, arising from a portion of the poison still lurking in the system, advised a fourth mercurial course, but although attended with partial relief during the existence of the pytalism, the rheumatism shortly after returned with redoubled violence, in which state the patient came under my observation.”

The observation of Mr. Hunter, “that not one in fifty cases of chancre would escape the lues venerea, if cured locally,” when placed in opposition with the experience of the military surgeons above stated, appears to prove one of two things, either that Mr. Hunter was mistaken, or that the poison has become much milder in its effects.

First—Was Mr. Hunter mistaken? Speaking of the acrimony of the poison, he observes, “Venereal matter must in all cases be the same; one quantity of matter cannot have a greater degree of poisonous quality than another; and if there be any difference, it is only in being more or less diluted, which produces no difference in its effects. One can however conceive, that it may be so far diluted as not to have the power of irritation. The variation of the symptoms in different persons depends upon the constitution and habit of the patient at the time. What happens in the inoculation of small-pox strengthens this opinion. Let the symptoms of the patient, from whom the matter is taken be good or bad, let it be from one who has had many pustules, or from one who has had but few, let it be from the confluent or the distinct kind, applied in a large quantity or a small one, it produces always the same effect.

In a small pamphlet submitted to your notice, I have stated my conviction, that the poison or poisons producing gonorrhœa and chancre *do vary* in their acrimony, and are arising *de novo* daily.—that the majority of venereal sores are not true syphilis, or, in other words, are not followed by secondary symptoms, and, therefore, require for their cure little or no mercury.

Now, if we can throw off the idea of the venereal poison being like small-pox, a specific, uniform, and unvarying poison, and believe that it *varies in acrimony*, not only from the constitution, but from the *habits of life* of the patient, then nothing is more reasonable than the belief that the effect will also vary in severity.

It is well known that the disease is milder in France than in this country, which would appear in a great measure to be owing to

the necessity on the part of cleanliness and personal hygiene that they may not be the cause of "pale of health" by means of ablu-
ence.

Mr. Hunter's comparison of the venereal poison with small-pox is, I think, inadmissible; since while small-pox produces small-pox or measles, three persons, having connection with one female, may have gonorrhoea, chancre, or bubo; and even these varieties may vary in acrimony. Now, while the cause which produces these diseases is one and the same, when once removed from the woman, it does not necessarily maintain its original character; the effect is not necessarily the same as the cause; for, if so, the excoriation from venereal gonorrhoea must be chancre, and the excoriation of a chancre must be chancre also, or, if the discharge of the matter comes in contact with the mucous lining of the urethra, it should produce gonorrhoea, whereas, either of these effects is, as far as I have seen, extremely rare. While, therefore, it is possible Mr. Hunter might overrate the comparative number of cases, which, in the absence of mercury, would be followed by lues venerea, I hold it to be extremely probable that, at the time he wrote (now about fifty years since), the venereal disease or poison possessed a higher degree of acrimony.

At page 274 of Mr. Abernethy's Lectures on Surgery, speaking of the venereal disease as described by Hunter, he observes, "This disease has almost become extinct, or is so much modified as to be unlike that which Mr. Hunter has described, and which I had an opportunity of observing in the earlier part of my life."

It is an opinion very generally entertained that venereal bubo is a sign of the absorption of the poison, or, in other words, of the contamination of the system; there is, however, I believe, little reliance to be placed on this symptom, for, in the first place, any irritation in the urethra or on the penis may produce a bubo; in the next, secondary symptoms frequently follow a sore without bubo; in the third place, bubo, or inflammation of the glands in the groin, or indeed of any part of the body, frequently arises from cold or rheumatism, or any like common causes. While such explanations are at hand, why have recourse to hypothesis, for after all that has been said and done, I contend, that the opinion that the venereal poison is absorbed into the body, is not substantiated by facts or warranted by symptoms.

I shall here take leave, I trust not uncourtously, to express, freely and unequivocally, my dissent from the views and treatment of bubo as inculcated at page 205 of Mr. Judd's recent work on *Urethritis and Syphilis*. Unless it can be proved that secondary symptoms have arisen from bubo,

MR. EAGLE ON SYPHILIS.

unaccompanied by any primary sore, I am quite at a loss to comprehend the propriety that bubo is a venereal disease. Unless similar in its nature, it effects to a chancre, the only difference being in size; unless all this is established by facts (with the opposing evidence), it is fair to treat the opinion as hypothetical.

For 1st. I have inoculated a sound person three separate times from three distinct buboes (following venereal sores), without in either case producing contamination.

2ndly. "With respect to absorption, even when the disease is followed by secondary symptoms." Mr. Hunter says, "we may observe, that even the blood of a pocky person has no power of contaminating, and is not capable of giving the disease to another, even by inoculation; for if it were capable of irritating a sound sore to a venereal inflammation, no person that has this matter circulating, or has the lues venerea, could escape having a venereal sore whenever he is bled, or receives a scratch with a pin, the part so wounded turning into a chancre. For if the venereal matter be on the point of the lancet or on the point of the pin, the punctures must become chancres."

Again, as to the venereal bubo containing chancreous matter, it might as well be argued, that when suppuration takes place in any part of the glandular system during variola, scarlatina, and rubiola, such matter would possess the specific property of each disease; or, to go on with the argument, that the matter formed from suppuration of a gland, from a dissecting wound, must necessarily contain matter of the same quality as the original. The same reasoning, for aught I see, might be applied to natural poisons, the poison of the viper, &c. The treatment of bubo then, in my humble opinion (in the language of Dr. Titley), "is not to be influenced by the consideration, founded on sheer hypothesis, that the glandular enlargement depends upon the absorption of a specific virus."—Page 119.

2ndly. Of the state of disposition.

Mercury cures the action but not the disposition. "Hence when a part is contaminated, and under the disposition to disease which should show itself at a certain time, mercury will protract that period, and the disease will not show itself so long as the constitution is under the influence of mercury. But all this time the disease will not be cured. After the mercurial irritation has ceased, the venereal disposition, which has existed ever since the parts were contaminated, will come into action; that is, the disease will appear, and in this state will be cured. These principles, being established, explain at once the difficulty that

existed, whilst attempts were made to eradicate the virus." Page 433.

3rdly. Of the state of action.

"Mercury cures the venereal action." We define more precisely what is venereal action, it is impossible to speak definitely of the action of mercury, since daily experience convinces me, that many effects imputed to the venereal poison, are neither more nor less than productions of the mercury. I conclude then,

1st. That the occurrence of venereal sores while the body is under the influence of mercury, proves that mercury does not prevent contamination.

2ndly. That mercury does not prevent the disease from running a certain course. By this I mean the occurrence of lues venerea. If this be true, it follows,

3rdly. That the continuance of the mercury for three weeks after the primary sores have healed, with a view to eradicate the virus, is perfectly unjustifiable both in theory and practice.

4thly. That there is no legitimate ground for believing that the venereal poison is ever absorbed into the body.

5thly. That the majority of venereal sores are not followed by lues venerea.

6thly. That the venereal poison varies in acrimony.

7thly. That the majority of venereal sores, which are not followed by lues venerea, are, in all probability, the production of the same poison that produces true chancre, only in a minor degree of acrimony.

It was my intention to have stated the facts on which I found the opinion, that the disease called "venereal rheumatism" is, more properly speaking, *mercurial*,—a consequence of the remedy and not of the disease. As, however, these remarks have extended to a length beyond my original intention, I cannot presume to trespass farther at present on your valuable space.

FRANCIS EAGLE.

29, Poultry, Feb. 9, 1836.

NEW RESEARCHES ON THE MOVEMENTS OF THE HEART.

THE theory of the movements and bruits of the heart still remains in great obscurity, notwithstanding the labours of Messrs. BOUILLAUD, PIGEAUX, MARC D'ESPINE, MONTE, and MAGENDIE, each of whom has formed a different theory. The researches of the Dublin Commission, composed of Drs. CORRIGAN, LAW, NOLAN, &c., ought to give birth, if not to the best, at least to the newest explanation, which is always

something in the way of an hypothesis.

In the mean time M. BEAU, one of the most intelligent internes of the school of Paris, after having made several experiments on cold and warm blooded animals, has arrived at conclusions, that seem to be supported by the facts which he produces, however contradictory some of them may be to our received notions. We cannot detail the experiments which form the basis of this long memoir, but will refer to them in such a manner as will render our description of M. BEAU's ideas intelligible.

The heart is the seat of two principal movements, which alternate with each other, and on whose existence all writers are agreed; in one, the inferior part of the heart or its apex is carried forwards; in the other it is the superior part or base of the heart which advances, while the point retires towards the dorsal parietes of the chest; we may call the sound which attends the first of these movements the inferior sound (the first or dull bruit of authors); the second gives the superior bruit (the second, or clear sound). It is also very generally admitted that the first is a movement of contraction (systole); the second, a movement of dilatation. Laying aside the manner in which other authors have endeavoured to explain the mechanism of these two movements, and particularly of that by which the point of the heart is carried forwards against the parietes of the chest, let us see how M. BEAU renders an account of the latter phenomenon. In physiology, all reasoning should be founded on observation and experiment. This grand truth, first established by our countryman Bacon, for the natural sciences, is at the present day applied with success to the investigation of the laws that govern medicine and physiology, by two distinguished physicians, Messrs. Louis and Magendie: the necessity of abandoning hypothesis for observation is daily gaining more ground, and the time is doubtless not far off when the science of life will progress in proportion as we abandon idle speculation for the study of the phenomena of living bodies.

The first experiments made by M. BEAU were performed on frogs. On exposing the heart of one of those animals we are struck with a double movement of dilatation, which is very remarkable, and affects at

separate times the upper and lower moieties of the organ: if we ~~pay attention to~~ these two movements, we find they depend on the auricle and ventricle, which act in the following manner, viz.: contraction of the auricle with dilatation of the ventricle; contraction of the latter followed by dilatation of the auricle, and the repetition of the same movement. When the heart is examined in the same animal, after the vascular system has been emptied by divisions of the aorta, we can still follow the movements of the organ for a few minutes: the auricle first contracts, then the ventricle, but not immediately: thus we observe the following series;—contraction of the auricle; repose; contraction of the ventricle; repose, more long than the former one: then continuation of the same series. Here there is an essential difference between the movements of the heart when full and empty: in the former we have a dilatation of the auricles and ventricles; in the latter case the dilatation is marked by a repose, and hence we are led to the conclusion that the dilatations of the heart are passive, and depend on the force with which the blood is driven into them. Having thus exposed the nature of the heart's movements in a state of plenitude and vacuity, the author asks "How do we explain the projection forwards of the apex during contraction of the ventricles? But here another question presents itself—Is the apex of the heart really thrown forwards against the parietes of the chest during the systole? M. BEAU thinks decidedly not.

Inspection of the heart in a living animal shows that the parietes of the ventricles are shortened in all directions; the apex is drawn up towards the base, and performs a movement from below upwards, and from before backwards: on the contrary, the impulse of the heart's point takes place immediately before the systole, and depends upon the manner in which the blood is driven from the auricle against the parietes of the ventricle. This is a point in which the author is completely in contradiction with the opinions commonly received; it remains for future experiments to confirm or overthrow his ideas. Let us repeat them again to avoid all misunderstanding:—

1st. In the systole we have retraction of the ventricle, without any projection forwards of the heart's point.

2nd. In the diastole there is a general expansion of the ventricle, particularly of its point, which is carried forward and strikes against the chest.

But the above propositions are not the only ones in which M. BEAU finds himself opposed to other writers. If we turn to the succession of the heart's movements, we find a difference which is worthy of attention.

M. BEAU, as well as all other writers, admit two movements, an inferior and a superior one; now if we analyze these two movements, we shall find each composed of two other movements, which we may represent in the following order:—

Inferior movement	{ Dilatation of the ventricle; Contraction of the ventricle.
Superior movement	{ Dilatation of auricle; Rest; Contraction of auricle.

Now if we analyze the succession of movements adopted by authors, we have,

Systole of auricle	{ Diastole of auricle; Diastole of ventricle.
Systole of ventricle	Repose.

Here also the difference between the two systems is striking. M. BEAU places the ventricular diastole between the systoles of the auricle and that of the ventricle; while in M. HORE's explanation we have the ventricular systole placed between the systole of the auricle and the dilatation of the ventricle, a succession which is not very conceivable.

But it may be objected that the experiments of M. BEAU were made on animals with a single heart. To obviate this the author continued his researches on dogs, rabbits, and birds (experiments for which we must refer to his memoir), and found that in animals with a double heart, the movements succeed in the following order:—

Inferior movement, comprising

{ Augmentation of all the diameters;
 { Increase of the ventricular diameters;
 { Diminution of the ventricular diameters;
 { Return of the point to its natural state.

Superior movement

{ A beginning, coinciding with the dilatation of the auricles;
 { A middle repose, very sensible;
 { A termination, coinciding with the contraction of the auricles.

From the above theory it is easy to deduce the author's explanation of the sounds of the heart: it differs little from that given by M. MAGENDIE: the foundation is the shock of the heart against the thoracic parietes; the inferior movement produces the first sound: the superior movement the second: so far the author agrees with M. MAGENDIE; he only differs from him in the explanation of the manner in which the two shocks are produced. M. MAGENDIE attributes one to the contraction of the ventricles, the other to their dilatation: while M. BEAU explains the former by the dilatation of the ventricles, and the latter by the dilatation of the auricles.

The first bruit corresponds to an elevation of the soft parts over the heart's point. The second bruit is not commonly attended with a similar phenomenon; however, M. BEAU assures us that in six cases he has observed an alternate elevation between the 2nd and 3rd intercostal spaces, corresponding to the second sound of the heart.

The duration of the different sounds, and the repose, as determined by auscultation, is, according to LAENNEC, as follows; in a complete pulsation one-fourth is occupied by repose of all the parts; one-half by contraction of the ventricles; one quarter by contraction of the auricles (1st and 2nd bruit). The author's researches furnish a different result. According to M. BEAU, if a pulsation measures one second, it composes a true measure à trois temps, and the first bruit, the second bruit, and the repose, will be represented by counting 1, 2, 3.

DERANGEMENT OF INTELLECT RESULTING FROM SABRE CUTS ON THE HEAD.

We extract the following curious case, related by M. BIESKE, from the last Number of the *Berlin Gazette of Medicine* which has reached us. (No. 52, Dec. 30, 1835.) Physicians in all countries are agreed on

the difficulty of diagnosing disease of the nervous system, but surely never was a case so grossly mistaken by men of high rank in the profession, as the one we are about to detail:—

In the month of April, 1814, the author (M. BIESKE) was called on to attend Colonel Count BLUCHER, son of the celebrated Prince of that name. The patient laboured under a tendency of blood to the head, and was troubled with hemorrhoids. The symptoms were easily removed by blood-letting and purgatives, and the patient returned to the amusements of Paris, where he was then stationed; in a short time however he again began to complain of tightness and pain about the head, with impossibility of sleeping. The pulse was now quick and full; the skin warm and dry; the inflammatory symptoms were removed by mild diaphoretics and a warm regimen; however, a little confusion in the ideas seemed to remain after the recovery of the patient from this slight attack. Dr. BIESKE considered this symptom, which was soon joined by a return of anxiety, insomnia, and tightness of the head, as depending upon *hypochondria*, and hoped, both by acting upon the abdominal cavity and by sulphureous baths, mineral waters, and relief of the patient's mind, to obtain a complete cure. He took this opportunity of examining the state of the wounds which Colonel BLUCHER had received some time before at the battle of Dresden. They were healed, but the cicatrices still betrayed the extent and nature of each injury. One sabre-wound existed near the junction of the occipital and right parietal bones: it was excessively deep, and had probably penetrated through the inner table of the skull. A second sabre-cut, on the left parietal bone, seemed more superficial; a third, near the junction of the parietal with the frontal bone, on the right side, was also deep, and had probably penetrated into the cavity of the skull. There was also a cicatrix on the neck from a lance-wound, and a second on the right side of the chest: this latter had penetrated deeply into the substance of the lungs, as was shown by the violent hemoptysis and other symptoms which accompanied and followed the wound. The patient, thus severely wounded, and taken prisoner, was brought into Dresden, where he was attended and cured by BARON LARREY, Dr. OMLE, &c.

Colonel BLUCHER now exchanged for a French General; his health soon recovered, established, and he followed the allied army amidst all the fatigues of a winter campaign from the Rhine to the walls of Paris.

In the month of May, 1814, the patient left Paris with the intention of taking mineral baths; but was prevented by some indisposition; he also now conceived the strange idea that he was possessed of a secret which would preserve the kingdom of Prussia from all dangers, and that his neighbours were constantly at work either to force this secret from him, or to deprive him of life, and discover it in his entrails. It was impossible to convince the patient, by any moral reasoning, of the folly of the ideas by which he was possessed; his physician, therefore, ordered some compound tinct. of bark, with tinct. of rhubarb and wine. The patient now, for a short time, thought himself cured, but his irregular ideas soon returned, and it became necessary to hold a consultation of the most eminent physicians in Berlin; their prescriptions, however, were not followed by any beneficial result, and the patient continued to regard them as fiends and persecuting demons. Dr. Bieske, who still preserved some share of the patient's confidence, hoped to obtain an amelioration, by acting on the intestinal canal, and by exercise; yet it was impossible to overcome the morbid mistrust which constantly occupied his mind; in the intervals of lucidity, he often complained of confusion in the head, vertigo, and sparks crossing the eyes.

Here we cannot help remarking on the tinacy of his medical attendants, in attributing all these symptoms to hypochondria, instead of turning their attention to the state of the brain, which had evidently suffered from the wounds received at the battle of Dresden. Far from pursuing an antiphlogistic treatment, the opposite method was pursued with a fatal perseverance; thus (to resume our author's history of the case) Dr. Bohn, one of the attending physicians, advised him to drink champagne; under the stimulating influence of which beverage, he felt himself comfortable for a short time; but, on the following night, the patient was very uneasy and agitated, and the attacks of vertigo were excessively violent; the pulse was now full and hard; the face and eyes were much injected; the circulating system was greatly excited. Dr. Bieske ordered some blood to be drawn from the arm, but the patient obstinately refused; he was, therefore, obliged to apply twelve leeches, and recommend a more cooling diet. The patient now felt much

better, his appetite returned, and, faithful to the ordonnance of Dr. Bohn, he drank every day a bottle of champagne!!!

The baneful effects of such treatment were not long without manifesting themselves; the vertigo again appeared with excessive violence, and M. Bohn was compelled to order venesection, with a cooling diet, and the use of sulphur. After the abstraction of some blood, and the administration of a few doses of sulphur, the patient found himself much relieved; however, the sudden change from champagne to cold water inspired his mind with fresh distrust; he now refused every kind of medication, determined on treating himself, and for this purpose made a journey on foot into Sicily, from which he returned in eleven days much more ill than he set out.

The patient's state now seemed very serious, and a fresh consultation of the Berlin physicians was called by Prince Blucher. On the 14th of November, 1814, the patient was examined with care, and the physician-general gave it as his opinion, that the disease had no connection with the wounds received at the battle of Dresden, but consisted in an aberration of the intelligence, which would best be treated by occupation, and the effect of moral agents. These latter, however, had no influence on the disease; the patient became so unruly and distrustful, as to endanger his own life and that of others; he often walked about at night with loaded arms, and once challenged a superior officer in duel, who, he imagined, threw some shade on the glory of his father. A medical examination of the patient again took place, in consequence of this circumstance; a decided opinion of mental derangement was given, and the duel of course prevented; this enraged him to such a degree, that he formed the resolution of insulting, or even killing, his adversary, whenever he might meet him. This design was frustrated by proper precautions, and the impossibility of avenging his honour had such an effect on the unfortunate patient's mind, that in the midst of a breakfast given to his friends, he fired a pistol loaded with ball into the left side of the chest near the clavicle; the wound, although dangerous, was not mortal; the bullet did not penetrate through and through the chest, but seemed to remain lodged under the left scapula; the hæmoptysis and other symptoms evidently showed a wound of the lungs, of which however the patient was completely cured. It is unnecessary to go through the various methods of treatment by turns proposed, but all fruitlessly; confined at one time, at another allowed absolute liberty, the patient was at length sent under proper care on a journey into the neighbourhood of the Rhine, but returned after a lapse of a year without any benefit.

He now lived without observing any regimen; appetite good; slept well; seemed to enjoy excellent health. However, he seemed frequently to suffer in the head; the hand was constantly carried to the forehead or head, and the patient at these times expressed his suffering by crying, "Oh, God, my head" (*O Gott, mein kopf*). His folly now became of an absurd kind; he believed, not only that his food and drink were poisoned, but that a portion of his strength was removed each time the hair was cut, and hence refused to be shaved or have his hair cut; he also conceived that a part of his secret was contained in his excrement, and always satisfied nature in a remote and unfrequented place, after which he carefully buried the precious deposit.

In this melancholy state the patient survived, without any remarkable change, from the year 1811 to the 10th October 1829. The author does not make any allusion to the symptoms which immediately preceded death. The body was examined on the 11th of October.

Autopsy.

External Examination.—A deep cicatrix, two inches long, on the right parietal bone; a second of similar extent near the junction of the parietal and occipital bones on the right side; a third cicatrix one inch and a half over the left parietal bone; on the body a large cicatrix adherent to the second and third ribs on the left side of the breast near the clavicles; behind, near the twelfth dorsal vertebra, two cicatrices; above the right elbow-joint, a transverse large cicatrix adherent to the os humeri; the fingers of the right hand, except the thumb and index-finger, were contracted, and united together by cicatrices; on the outer side of the left calf a round cicatrix, which seemed to have resulted from a gunshot wound, a second over the left knee-joint, from a penetrating wound. On removing the skull-cap the dura mater was found to be united to the bone more closely at the points corresponding to the wounds; the anterior one had evidently penetrated into the cavity; the posterior cut on the right parietal bone had also penetrated, but not that on the left side. The whole anterior surface of the hemispheres, superiorly, was covered with a whitish firm layer, about the thickness of a knife-blade, and similar to that produced by inflammation. The base of the brain presented nothing abnormal. On dividing the substance of the brain the white matter was found somewhat injected, and the ventricles contained a little more fluid than usual. The cerebellum healthy.

In the cavity of the chest the lungs were closely united to the costal parietes; in the midst of the substance of the left lung, opposite the third and fourth ribs, was found a

lead bullet, which appeared in several places, as if it had been cut with some sharp instrument. The third and fourth ribs had been evidently fractured inwards, and were united in an obtuse angle by bony deposit. The examination of the other organs revealed nothing worthy of notice.

The cause of the lesion of intelligence in this curious case, was evidently a chronic inflammation of the membranes covering the cerebral hemispheres. Unfortunately this cause was completely overlooked by the physicians who attended General Blucher, and a treatment was adopted which was rather calculated to aggravate than to allay the morbid irritation of the sensorium. This is the more remarkable, as the French surgeons who treated the patient in 1813, after the battle of Dresden, expressed their fears that at some future time the wounds of the head might give rise to a derangement of the intellect. The length of time (sixteen years) during which a large musket-ball remained imbedded in the substance of the lung without giving rise to any symptoms, is also another curious circumstance.

To the Editor of THE LANCET.

SMALL-POX AND VACCINATION HOSPITAL, ST. PANCRAS.

*Report of Dr. GREGORY, Physician, issued
Feb. 1836. (Abridged.)*

DURING the past year 401 persons have been treated within these walls, and so many centres of infection removed from the metropolis. Of that number 89 have died, and 312 have been restored.

4140 persons were vaccinated at the hospital in 1835; and 1767 persons, chiefly medical practitioners, were supplied with vaccine lymph, for use, at home and abroad.

The records of the hospital, during the past year, sufficiently attest that the hopes once entertained of banishing the small-pox from the earth are visionary. Thirty-six years have elapsed since the general diffusion of vaccination throughout this country; yet small-pox still exists, and, by the bills of mortality, may be shown to have proved fatal to 863 persons in London alone during the last year. In various parts of the country it has shown itself during the same period. Nor do other quarters of the globe enjoy an exemption from the disease. On the continents both of Europe and Asia small-pox has recently occasioned considerable devastations.

The experience of the past year shows,

certainly, that the confidence of the public in and about London, the power of vaccination has in no degree diminished. The numbers vaccinated at the hospital in 1835 exceed that of any former year, and in no instance has any doubt or distrust been manifested by the parents of the child.

The records of the hospital show further that the security of vaccination, though so remarkable in the early periods of life, is not so complete and permanent in after-life as at one time might have been anticipated. 44 persons labouring under small-pox have been admitted during the year, who in early life have been vaccinated. All of them, with few exceptions, were adults, an interval, varying from ten to thirty years, having elapsed since the date of their vaccination. Two-thirds of this number had small-pox in a mild form, wholly devoid of danger. The remaining third were less fortunate, having passed through the disease with greater or less degrees of severity. Still the mortality in this class of patients was very small, hardly amounting to 5 in each 100; while the unvaccinated perished in the proportion of 33 in 100. These considerations tend to show that vaccination is still entitled to the highest praise as a means of diminishing both the quantity and the severity of small-pox; that it is an object of national importance to encourage and foster it; and, lastly, that the attention of medical men cannot be too strongly called to the necessity of carefully selecting the lymph they employ, and accurately investigating the several causes on which its diminished efficiency in the more advanced periods of life may depend.

31, Weymouth-street, Feb. 4, 1836.

THE LANCET.

London, Saturday, February 20, 1836.

ANOTHER inquest has been held upon the body of another victim of the satanic system of quackery, and another upright English jury has returned a verdict of "manslaughter" against one of the parties implicated in the abominable proceeding.

But how is it, we ask, that the chief culprit is allowed to escape in these atrocious malpractices? How is it that the principal offender is allowed to pass unscathed from the inquiry, and that the mere agent, the ig-

norant tool of the mercenary destroyer, is the only person punished?

Many complaints have reached us respecting the conduct of the Coroners at these quack victim inquests. Charges of ignorance, allegations of partiality, and imputations even of corruption, are thrown out against some of those functionaries. That non-medical Coroners must act as blockheads in their offices, is a necessary consequence of their ignorance; but we had hoped that they would so conduct themselves as at least to remain free from accusations of knavery. That many of the non-medical Coroners are most respectable men we freely admit, and hitherto we have seen no just ground for excluding Mr. BAKER from amongst that class. We must freely tell him, however, that his behaviour at the late inquest on the body of Captain MACKENZIE, at the Ratcliffe workhouse, has been viewed by many persons with suspicion, and that reports unfavourable to his official character on that occasion, are in a rapid course of circulation. If Mr. BAKER be capable of forming an opinion on such a subject, we would ask him what he would think of the moral principles of a man who, in a sound state of mind, would advertise one medicine as a cure for all diseases. If Mr. BAKER be not lost to reason,—if his mind be not divested of every portion of common sense, he must know that if there be people so devoid of understanding, so credulous as to place any belief in the infamous puff of the mercenary quack who sets forth such an advertisement, they must necessarily, in numerous instances, pay the penalty of DEATH for their folly.

Under this view of the case, the criminal ought to be brought home to the offender in the first degree, and whenever it is proved in such cases that the cause of death is to be found in the poison, or in the effects of MORISON'S PILLS, THE VERDICT OF MANSLAUGHTER SHOULD BE RETURNED AGAINST MORISON HIMSELF. This would be an application of the law to the source of an

of the calamities which is at this moment so severely affecting society. Is there any thing so redeeming in the character and conduct of MORISON, that he should be made an exception to the ordinary rules of law at coroners' inquests? Ought he not to be treated as a Fellow of the College of Physicians, or a member of the College of Surgeons, would he be treated under similar circumstances? Take the case of either of those legally qualified practitioners, and let us see what would be done. Say that one of the parties in question imagines that he has discovered a remedy for all diseases. He prescribes it in a multitude of cases. It is proved by indubitable testimony, that death, on several occasions, has been the dreadful result of the use of the medicine. Still the practitioner persists. He puffs his own skill, extols the power of his nostrum, and directs the medicine to be again taken. A chemist supplies the drug, in conformity with the direction of his employer. The unsuspecting patient swallows the poison and dies. An inquest is held on the body. Who was guilty of the manslaughter in this case? The chemist or the doctor? The principal or the agent? There can be but one reply to such a question.

But is it *manslaughter*? Is it not *murder*? We repeat the deliberate and solemn inquiry,—Is not the person who kills under the circumstances we have just stated, guilty of committing the crime of murder? We believe, that some of the best-informed jurists in this kingdom will answer in the affirmative, as we are not aware that any line of distinction can be drawn between the man who, in order to make money, destroys life by poison, and the man who, with a view to enrich himself, plunges a knife into the bosom of his neighbour.

We shall not at present pursue this subject further, with reference to any inquests which have been recently held, but we hope to be able to publish in the next number of *THE LANCET*, a report of the evidence which was taken at the late inquest on the body

of Captain MACKENZIE, which concluded, after several days' sittings, on Wednesday last, some hours after midnight, in a verdict of "manslaughter." But we ask, Is society to continue to endure this evil without making an effort to throw it off,—a calamity almost as fatal in its results, as the plague or the cholera? Whatever is secret in medicine is based in knavery, and we unhesitatingly state that the time has come when the system of quackery in medicine must be put down by the arm of the law. At any rate an attempt shall be made to ascertain whether the law be powerful enough to arrest the proceedings and, subvert the machinations of a few mercenary and sanguinary adventurers, who now, to the disgrace of the medical profession of England, circulate their baneful and odious trash under the sanction of a Government stamp. Cannot the members of the profession petition both Houses of Parliament for the suppression of quackery? Ay, can they! and with every prospect of success. In order to accomplish this object, however, there must be co-operation among medical men. Unity of action and energy must be manifested in giving the proceedings proper publicity and influence. If they consider that quack medicines ought to be sold, let them remain passive. If, on the other hand, they consider that the use of quack medicines is injurious to the welfare of society, and is the cause of death to hundreds of their fellow creatures, they are called upon by every sense of duty, justice, and humanity, to take immediate measures for the suppression of this no longer supportable evil.

THE Charter of the Metropolitan University will be laid on the table of the House of Commons on or before the 24th instant. A letter, written by Mr. WARBURTON, on the subject of the contents of this instrument, to the LORD PROVOST of Edinburgh, was referred to in the *Globe* newspaper

about a week since. In the absence of accurate information on the subject, Mr. WARBURTON has merely adverted to what may probably constitute some of the conditions of the Charter, in general terms. Ministers may be assured, that no member of the legislature could have been consulted with greater advantage than Mr. WARBURTON. At any rate, that gentleman will have the consolation of knowing, that if the new Charter should fall short of the expectation of the literary portion of the public, he will in no respect be concerned as the author of the disappointment. It is deeply to be regretted, that Ministers should feel that they are too tightly bound down by old customs to make the Parliament acquainted with the principles on which they are about to exercise the royal prerogative in founding a Metropolitan University. It is ever the case in this country, that although we see the coming evil, we have not the power to avert it, though, to be sure, after it has arrived, we have the privilege of complaining, which must be a great consolation to the people of a free nation.

The following is the statement which appeared in *The Globe* :—

"EDINBURGH TOWN COUNCIL, TREASURY.—A letter from Mr. Warburton, M.P., in answer to a letter from the Lord Provost, was read, in which he assures the Council that no one could be more anxious to prevent the establishment of any new monopoly of teaching, and to see instituted some uniform system of medical instruction and examination, to serve as a basis for granting to persons properly instructed and examined the enjoyment of equal professional immunities in every part of the United Kingdom. Whether such a plan could be carried into effect by means of any Crown charter, might reasonably be doubted. He thought government would scarcely be justified in delaying to constitute the proposed new University of London, for the purpose of maturing beforehand, and incorporating with the scheme of that university, a comprehensive measure of medical reform. The Government, he thought, should constitute the new University, investing it with all the privileges appertaining to such institutions, reserving to itself the power of modifying its laws and ordinances, so as to render them generally consonant to any general plan of medical

reform that may hereafter be approved of. On several points, he was not informed of the details of the proposed plan. The most important that he was aware of as affecting the interests of medical schools in general was, that "no medical school whatever was mentioned in the charter by name." A matter of importance for which the London University was contending was, that no teacher of any medical school, and no medical or surgical officer of any hospital, shall be a member of the Board of Examiners. The Council directed copies of this letter to be communicated to the Secretary of the University for the information of the Senatus, to the Royal College of Physicians, and the College of Surgeons."

A BODY of young gentlemen having admission to the halls of the University of London, have, after the lapse of a month, come forward in aid of the plea that public examinations should form an imperative feature in the constitution of our governing medical bodies. These gentlemen formed no part of the meeting of medical students who were assembled at the Crown-and-Anchor Tavern on the 18th instant, for on that occasion the resolution for a petition to the House of Commons in favour of public medical examinations was carried unanimously, and the Chairman was directed to sign the document on behalf of the meeting, without ten hands being raised against the proposition. There is this difference, however, between the proceedings of the thousand and some hundred students who were assembled in the Strand, and the party of students who have since done something else in support of the demand for public examinations. The prayer of the one must be regarded by all as the emanation of a noble courage; the protest of the other is the result of what too many will ascribe to youthful fear. The demand of the one is addressed to the House of Commons; the declaration of the other to the House of Apothecaries. The cry of "marked men" has been raised at the University of London, and the timid and the apprehensive have fallen at the feet of the Examiners at Blackfriars-bridge, with

this assurance:—"We aided not in the communication of the CHANCELLOR of the
"denomination of your secret proceedings in
"general, or of your private rejection of
"our fellow student Mr. SMITH, in par-
"ticular."

In speaking of the document just submitted to the view of the Apothecaries' Company as an aid of the prayer,—and a most valuable aid it is,—of the great meeting of students, we do so from regarding it as an important proof of the iniquitous power and influence possessed by those secret tribunals which can, by exciting the terror of some candidates for examination, extort such a declaration from one third in number of the intelligent students of the most liberal public seminary for instruction in the kingdom.

When a black man encounters a lion, or meets with a bull, he lies down on his back, and pretends to be dead, believing that the giant animal will then only snuff and pass on. In the College of Physicians,—to go from a great topic to a little one,—Sir HENRY HALFORD enacts the trembling man, and medical reform the lion, and whenever the lion wags his tail, the cunning President pretends to sleep. But the lion will eat him up notwithstanding. The last occasion on which Sir HENRY "slept" in the chair, was during the late motion "that Licentiates of five years' standing should be eligible to be balloted for as Fellows." The mover and seconder having enforced the proposition as a measure of reform which was particularly appropriate at a moment when it was desirable to convince the Government that the disposition of the College was decidedly liberal, arguments in support or reply were awaited, or a tacit assent at once to the motion. However, it had been arranged beforehand by Sir HENRY, that nobody should reply, that the President should pretend to sleep, that every refractory fellow should be borne down with a cry of "question," and that even this trumpery motion for reform should be promptly rejected by the ballot. True to the word of command, the resolution was negatived by a majority of nearly three to one. The result was

The majority was partly composed of the following members of the Halford faction, amongst others:—Drs. LATHAM, WATERFIELD, WATSON, HUE, FANNY, MACMICHAEL, TURNER, and GEORGE MANN BURNOWS, whose name deserves to be written in full,—while Drs. CHAMBERS, SEYMOUR, M'GRIEK, HEWITT, and even Dr. PARIS, having begun to see the signs of the thing, purposely staid away. Drs. LATHAM and WATSON were particularly conspicuous in their outcries against any discussion of so contemptible a subject as reform in the College.

Up to the present hour, we have received no denial from Dr. W. CUMMIN, of the "Aldersgate School," of the correctness of the allegation, that he is the official colleague of Dr. MACLEOD in editing a journal which has been systematically devoted, from the first moment of its existence, to slandering the general practitioners in medicine in this empire, and, latterly, especially, to calumniating and vilifying, and fabricating falsehoods directed against, the characters of the students of medicine assembled in the metropolis.

LATE ELECTION

AT THE

RICHMOND HOSPITAL, DUBLIN.

We had not room last week for any part of the letter of our correspondent *Observer* in reply to the letters of Messrs. CRAMPTON, COLLES, and CARMICHAEL. We now, however, insert an analysis of its contents:—

Observer says that he felt it to be a matter of duty to publish the account which appeared under his signature,—not desirous to inflict obloquy on the gentlemen concerned, but to describe facts with fidelity, desiring at the same time to afford the implicated parties an opportunity of publicly rebutting, if possible, the statements which prevailed against them in Dublin. He says that he believed and still believes that his description of the former proceedings as regards hospital elections, of two of the Commissioners, Messrs. CRAMPTON and COLLES, were such as should have prevented their nomination on

this occasion, and he alleges that those two Commissioners in their reply have not relieved themselves from the odium of the allegation that they are "jobbers in public medical offices." For instance, he says that at the *Meath Hospital*, Mr. CHAMPION and three of his apprentices (one a nephew) fill four of the six medical offices. *Observer* argues that the appointment of the "Commissioners," though denied, is proved by their admission that they carried on an "official" correspondence with the government on the subject of Mr. ADAMS's fitness for the vacant office. He adds, "I beg also most distinctly to state that Mr. ADAMS was not a candidate until after the Commissioners were appointed," Mr. ADAMS himself declaring to his friends that it would be useless to annoy himself by any application on the subject, as he would have no chance of success with the present Government; and *Observer* says that he has reason to believe that Mr. ADAMS became a candidate solely in consequence of receiving a communication from one of the Commissioners immediately after their appointment. It must, however, be perfectly plain to *Observer*, that some of the statements in his letter form no reply to the third paragraph of the letter at page 680 of *THE LANCET*.

Observer stated in his former letter that the commissioners wrote to the government, recommending Mr. Adams's appointment on the grounds that it was necessary for the support of "the Medical School of Dublin." He says, "I now reassert that they did do. This official letter was in Mr. ADAMS's own possession for some days, and he took great pains to exhibit it, as a trophy, to his friends, more especially to his pupils, as evidence in favour of his capability as a lecturer."

With regard to Mr. CARMICHAEL, *Observer* thinks that the following passage in Mr. C.'s letter justifies a considerable portion of the remarks made on the resignation of Mr. CARMICHAEL: I resigned my situation of attending, for that of consulting surgeon; because, by doing so I secured the appointment of two gentlemen, whose long connection with the hospital, and well-tryed competency and worth, had been fully established; while, by the arrangements that have been subsequently made, I shall continue my visits to the hospital, &c."

With respect to the remark of Mr. CARMICHAEL on the long connection of Messrs. ADAMS and M'DONNELL with the Hospital, *Observer* says, "I am well aware that those gentlemen have been attached for some time to a school in the neighbourhood of the hospital; but it is a perfectly distinct establishment, and not even situated in the same street with it; nor did they ever hold in it even the offices of assistant surgeon." Respecting the testimony of Mr. CARMICHAEL that he has always heard Mr. ADAMS ex-

press liberal sentiments on political subjects, *Observer* says that whatever Mr. ADAMS may have expressed, he always voted in Dublin for anti-reform candidates. *Observer* was not the author of the letter in the *Freeman's Journal*, nor was he aware of its existence until he read it as a note to Mr. CARMICHAEL's letter.

Observer concludes by saying,—"You have mentioned in a late number that the authenticity of the petition presented to the Government, purporting to come from the Sisters of Charity, in favour of Mr. FERRALL, has been denied. I believed the petition was genuine."

We have here reduced into a comparatively brief space, those points in the letter of our correspondent, which we deem it fair, apart from the authority of his name, to publish in reply to authenticated documents, adding that while we know our correspondent to be a gentleman of the highest respectability in one of the professional circles of Dublin, there can be no doubt that he was misinformed on some points discussed in his former communication. With regard to Mr. CARMICHAEL, we feel bound to say that we have never before heard even a charge of jobbing in medical elections brought against him, and we are perfectly sure that no surgeon in these kingdoms will hail with greater pleasure the adjustment of medical law and hospital appointments on a just and honourable basis, with greater delight than that gentleman. At the same time we express a belief, founded on pretty good grounds, that no very long period will elapse before the task of exposing errors of medical misgovernment under the present system, will no longer need to be one of the duties of the medical reformers of Dublin.

PRESENT TO SIR CHARLES CLARKE.

To the Editor.—Sir, You have been unceasing in your endeavours to elevate the medical profession in public estimation, by fearlessly exposing, on the one hand, its corruption and mispractices to ridicule and contempt, and, on the other, materially promoting its interests, by showing a praiseworthy liberality in commending good conduct, and I, therefore, am convinced that you will derive a satisfaction in communicating to your numerous readers the following event, so honourable to the eminent individual who forms the chief object in it, which has lately taken place in this county,

Sir Charles Clarke, ever since he became one of our land-holders here—has resided among us during the great portion of each year, and it is not surprising that his high professional character should have prompted not only the medical practitioners in his neighbourhood to seek his advice in all cases of difficulty and danger, but that his council should be equally desired by our nobility and gentry. His active disposition made him always ready to attend to the calls of distress, and, to his credit be it told, he has been in the constant habit of lending his valuable services to all those who have sought his advice, without even excepting a fee. In consideration of this liberal conduct, the great bulk of the ladies of Norfolk unanimously agreed to present Sir Charles with a piece of plate, for which a large subscription was immediately made, and an order given to Storr and Mortimer, the goldsmiths, in Bond-street, to execute the same from a design made purposely by Chantrey, the eminent sculptor. I have the honour to be, Sir, your obedient servant,

CHIRURGUS.

— House, Norfolk, Feb. 12, 1836.

KING'S COLLEGE, STRAND.

To the Editor.—SIR,—As your numerous readers are extremely anxious at this moment to become acquainted with every circumstance that can elucidate facts relative to the conduct of certain individuals who pretend to be *liberal*, you may perhaps think it worth mentioning that the Worshipful Company of Apothecaries are proprietors in King's College, Strand. This simple fact may of itself be sufficient to account for the King's College students having come forward on the late occasion to *laud the disinterestedness* of the Rhubarb Hall examiners.

I have also heard it rumoured, that in consequence of the want of money at the institution, Sir Henry Hallford has been making an indirect application to the proprietors of the Drug Shop in Blackfriars, to get them to purchase some more King's College shares. I am, Sir, yours, &c.

AUSCULTATOR.

Ficcadilly, Feb. 16th.

PROFESSIONAL ADVERTISEMENTS.

To the Editor.—SIR,—While paying a professional visit this morning to an elderly gentleman of fortune, a very small publication, showily bound and gilt, containing three "Introductory Lectures," by Mr. Evans Riadore, was placed in my hands. I

felt much at a loss to elucidate the mystery, as my patient said that Mr. Evans Riadore was totally unknown to him, and that he could in no way account for the present. I thought at first that there must be a mistake, but in the title-page it was plainly enough addressed

"To ——— Esq., F. A. S. From the Author."

I then suggested that there might be another F. A. S. of the same name as my patient, or that Mr. Evans Riadore, being an F. A. S. himself, he had sent his *brochure* (a scarcely allowable proceeding, however) to the rest of the fellows; but, on examining the list, neither of these surmises was found to be correct. Upon a cursory examination of these lectures, I observed that they were composed with a considerable regard for effect, and that the author's address was duly given. Now, Sir, I beg to inquire the meaning of all this; and whether Mr. Evans Riadore has presented his introductory lectures to any other gentlemen who are totally unknown to him; and, in fine, whether it is becoming in a member of a liberal profession to follow in the track of the circular-circulating wine-merchants and merchant-tailors of the metropolis?—I am, Sir, yours &c.,

INVESTIGATOR.

London, Feb. 16, 1836.

METROPOLITAN MEDICAL UNION.

To the Editor of THE LANCET.

SIR,—In my address on the state and wants of the medical profession, delivered in the Council Room of the Town Hall, Ipswich, in the year 1834, I most earnestly recommended that a provincial association, similar to that already existing in the western division of the kingdom, should be formed. This, with me a very favourite and important object, has been most happily accomplished; but it seems that something yet remains to be effected. The western and eastern associations require a point or bond of union; and where could this be so completely established as in the metropolis? I do most sincerely hope that some leading members of the profession in London will immediately set about the formation of a Metropolitan Association, similar in principle to the Eastern and Western associations. For general and literary purposes we might unite, while we may hold our annual meetings in our own provinces, with the exception of every third or fourth year, when we might meet our metropolitan brethren in London.

Favour me by allowing a space in the pages of THE LANCET for the insertion of this suggestion, and if it should be so fortunate as to meet with your approbation, I trust that you will support it with your

wanted ability. I have the honour to remain, Sir, yours very respectfully,

J. BEDINGFIELD.

Stowmarket, Jan. 26th, 1836.

EULOGISTS OF RHUBARB HALL.

To the Editor of THE LANCET.

SIR,—In Roderick's journal of last week is printed a document headed "*Protest of the Students of Guy's Hospital against the late proceedings at the Crown-and-Anchors*" said by Roderick to have attached to it the signatures of 94 of the students of that hospital: now Sir, I think it right that you should be acquainted with the hole-and-corner manner in which this "protest" has been got up by its promoters, Messieurs H. C. Muggand and J. Bent. These huzzing busy bodies, who attend to every person's affairs but *their own*,—or they might perhaps, ere this, have been enabled, with the aid of a little favour at court, to pass the ordeal at Rhubarb Hall,—have got up this document expressly to court that very favour. I am sorry that their abilities and diligence need it. In that document they term the 94 who have signed it, a "large majority" of the students of Guy's, but to say the least of it, this is untrue. They also call the proceedings of that meeting "ill judged and violent," and state that they were "characterized throughout by party violence," which is notoriously false. Now, Sir, from the admission of two individuals whose names are attached to that document. I can assert that neither of them was present at the meeting; consequently they rely on the reports of others in making the allegations to which they have attached their names; and I believe that very many more, if not the majority of those who signed that paper, were not present at that meeting; and I can positively say that not a few repent having signed it; I have learnt this from their own lips. In addition to this, I may remark, that Messrs. Muggand and Bent induced several juvenile pupils (fresh from the country) to sign the paper in question, solely on the ground that they could not do wrong by following in the footsteps of their seniors. These young gentlemen will learn wisdom from experience. I refrain from saying any thing more on the subject of this "protest," than that we are greatly surprised in the Borough that any medical students, of whatever party, should be found

* 94 does not form a fourth part of the number of 400, which *Guy's Hospital* used to boast that it fostered per session. No wonder that medical reform is a repugnant topic in some nooks in that quarter.

to connive at and applaud the ungentlemanly and unworthy manner in which the worshipping examiner at Apothecaries' Hall acted when he questioned and rejected Mr. Smith. I am, Sir, yours very respectfully,

A GUY'S HOSPITAL STUDENT.

Guy's Hospital, Feb. 17th, 1836.

NOTE FROM MR. WATTS.—To the Editor.

Sir,—On reading over my letter in your excellent publication, I beg to say that I committed a quite unintentional mistake, when I stated that I had attended nine parishes for eighteen years. Several of them I have so attended, and others in intermediate spaces of time. This was what I designed to express. At the same time I beg to assure you and my professional brethren that my object in giving publicity to the Wheatenhurst Poor-Law-Union proceeding, was not with the slightest intention of doing Mr. Moseley any professional injury, but to point out the system as one which is degrading to the profession, and injurious to the poor. I am, Sir, your obedient servant,

THOMAS WATTS.

Frampton-upon-Severn,

Feb. 17, 1836.

CORONER FOR ABERYSTWYTH.—To the

Editor.—Sir,—Seeing by a letter inserted in THE LANCET of Feb. 13th, that you are anxious to ascertain the number of medical coroners in England and Wales, I beg to state that the Coroner for Aberystwyth, Cardiganshire, is Rice Williams, Esq., a medical gentleman who has filled the office of Coroner in that town for a length of time. I am, Sir, yours, obediently,

A STUDENT OF MEDICINE.

MEDICAL WITNESSES BILL.

To the Editor.—Sir, I enclose you a copy of a Petition to the House of Commons, prepared at a meeting of the committee of the "Bucks Medical Association," lately held at Aylesbury. It is now in course of signature, and will shortly be ready for presentation. The support of its prayer will be earnestly requested of the county and borough members. I have the honour to be, Sir, your obedient servant,

ROBERT CREELY, Hon. Sec.

Aylesbury, Feb. 15, 1836.

* * The petitioners draw the attention of the House to the fact that a coroner's inquest, without efficient medical evidence, can be but an empty form, and is, consequently, a source of useless expense, and

"in common with the medical profession, they consider it a great hardship that the law does not provide any remuneration for their important services." They accordingly conclude the petition by "respectfully, but earnestly, beseeching the Honourable House to afford them substantial relief from its manifest injustice, by the enactment of such a measure, as the Honourable House, in its wisdom, shall think fit."

The promptness and spirit with which this petition has been framed, deserve universal imitation in the profession.

HOUSE OF COMMONS.

Thursday, Feb. 18th, 1836.—Mr. WAKLEY this day gave notice of a motion for the 17th of March, for leave to bring in a bill for suppressing the sale of secret medicines, commonly called "quack medicines."

NEW METROPOLITAN UNIVERSITY.

Mr. WAKLEY.—Sir, the petition which I hold in my hand is from the Rev. JAMES ALEXANDER EMERSON, of the Hanwell Schools, in the county of Middlesex. And the petitioner states, that he has heard with surprise and regret that it is intended to limit the terms of the proposed Metropolitan University Charter to two institutions in London. He therefore prays, that the House will take into consideration the injustice to other scholastic institutions, of granting such exclusive privileges to those two. Sir, I will take the liberty of saying a word or two on this subject. It is very well known that, in April last, it was resolved by this House that an Address should be presented to the Crown, praying that his Majesty would be pleased to grant a Charter to the London University. On that occasion, a very large majority of the members of this House voted in favour of presenting that address; and solicitations came from all parts of the United Kingdom for the establishment of such an University, in consequence of the manner in which the Dissenters had been excluded from the privileges of the universities of Oxford and Cambridge. Sir, I do not complain of those institutions, and I, for one, never will consent to the throwing of power into the hands of those who are hostile to the proper authorities of the Universities of Oxford and Cambridge, or adverse to those institutions. (*Hear, hear, hear.*) But I would ask, in establishing a new university in this metropolis, are we to have another scholastic monopoly set up in this kingdom? And if a Charter is to be granted, which is only to embrace two or three

establishments, surely the privileges so conferred must be considered as a monopoly, because others will be excluded from the like enjoyment. I regret exceedingly that the Chancellor of the Exchequer is not here, as he promised me that he would be, to state to the House what are his intentions on the subject. The House having determined on voting the address to the Crown, which I have mentioned, is it right, I would ask, that the conditions of this new charter should be framed in secret, and that the members of the House are to know nothing of its conditions until the charter has received the sign manual? If that be the case, the abuse of the Royal prerogative cannot too soon be corrected. (*Hear, hear.*) Indeed I hope the House will now interfere in this matter, and call for a draft of the charter to be laid before it previous to its receiving the sign manual, for such a legal and authoritative instrument should not be promulgated until at least the legislature has been made aware of its express terms. (*Hear, hear, hear.*) In the constitution of the new university, there can be no law that will compel the students to reside under the immediate observation of the professors, a regulation so essential to their correct government and moral conduct; and yet, if the charter be one of exclusion, the students at the private schools, where the dormitories are under the direct control of the masters, will be excluded from the honours of the university, while those who are under no personal restraint or moral management on the part of the professors will receive all the benefits of the institution. I will only add that I trust Ministers will candidly and honourably state to the House what are the conditions of the Charter, because although it is easy enough to say that his Majesty's Ministers will hold themselves responsible should it contain any improper clauses, yet I do not know how they are to be made so, either to this House or to the public, when the document is completed. I beg to observe, in conclusion, that the gentleman from whom this petition comes, requests me to state that he forwards it without entertaining any political feeling whatever on the subject. He has none. He is sincerely attached to the Universities of Oxford and Cambridge, and he desires only that the public good may be consulted in the measures that may be adopted. (*Hear, hear.*)

Sir GEORGE said, that he could assure the House that the people of Scotland were extremely urgent that the disabilities under which the Dissenters at present laboured, should be removed as soon as possible.

Mr. TOOKER said, he apprehended that the petitioner had put an erroneous construction on the intended Charter, the petitioner believing that because two schools only would

be nominated in the Charter, viz., the London University and King's College, that therefore the privileges of the Charter would be confined solely to those schools. The fact was that power would be reserved to the Examiners of the Metropolitan University to name, from time to time, such other schools as should be considered, from their standing and reputation, fit to be added to the number of privileged schools, and which should be entitled to participate in the benefits and honours to be derived from the Charter.

The petition was then ordered to lie upon the table.

THE NEW QUACKERY.—*Westminster Medical Society*, Feb. 13.—**HAHNEMANISM.**—We have room this week only for the following:—

Dr. JOHNSON having moved the adjournment of the debate on this subject last week, he was now requested to take it up. In doing so, he briefly said that homœopathy, he believed, was not the real subject of debate on the last evening; but the proceedings then, rather formed an episode to it, something like a romance engrafted on history. He should leave others to hunt after the bubble, believing that it would burst in grasping. The doctrine of Hahnemanism was founded in error, and too often pursued in knavery, and he was convinced that the homœopaths treated the more urgent cases with our own remedies, and after our own fashion; yet who could expose the fact, for they took the precaution to furnish their patients not only with advice, but with the medicines. When they got old chronic or nervous cases, and not unfrequently imaginary ones, the doctrine of Hahneman was pursued. Chiefly from these reasons, he (Dr. J.) pronounced it to be a system of knavery and deception.

THE governors of the institution entitled the "Free Hospital," situated in Greville Street, Hatton Garden, will commit a gross error if they attempt to purify the air of their establishment by adopting the measures prescribed in the motion "relating to Mr. TWEEDIE," to be submitted to their notice on Tuesday next. There is another way of doing that. Mr. TWEEDIE has in the most straight-forward, prompt, and honourable manner atoned for the exceedingly incautious act which want of experience allowed him,—in common with Mr. J. H. GREEN, Mr. BRANSBY COOPER, and some other exceedingly "orthodox" but older and therefore less excusable gentlemen,—

to commit, and it would be a most unwise proceeding, after that step, to inflict the supposed punishment on Mr. TWEEDIE. Let the point be judged without prejudice; against the charge let the atonement be weighed; and we are quite sure that the instigations of no uncharitable and mistakenly interested persons will overbalance the just inclinations of the honourable-minded arbitrators. The chief parties in the affair should be advised to hesitate about pressing the matter any farther. The candour of Mr. TWEEDIE, in the admission of his error, and his attempt to redeem it, are, unless we be much deceived: worthy of imitation on the part of the gentlemen who may be his opponents. But *why* his opponents *now*?

The *Birmingham Journal*, of Feb. 13, contains a copy of a memorial presented to the King from the governors, trustees, and medical officers, of the Birmingham School of Medicine, containing a prayer, that "in order to give additional weight and efficacy to the institution," his Majesty would become a patron of the school, and allow it to be styled the "Royal School of Medicine and Surgery of Birmingham." The King consented, through Earle Howe, and at a subsequent meeting of the memorialists, their "humble and grateful acknowledgments" were unanimously voted to be "laid at his Majesty's feet," for his condescension on this occasion.

From a Correspondent. It is generally rumoured at the London University and Hospital, that it is the intention of the Council of the College of Surgeons to grant to the late pupil of Mr. LISTON, a public examination. Their announcement of the fact is awaited with anxiety.

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications to Mr. WAKLEY may be addressed to him at his residence, 35, BEDFORD SQUARE.

Mr. —. Nothing could have been more spirited or proper than the application to the Board of Guardians, and the refusal &c., under the circumstances stated.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

GIVEN IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XIII.

ATROPHY OF THE BRAIN AND SPINAL MARROW.

(Continued.)

GENTLEMEN,—In our last lecture we were occupied with a consideration of atrophy of the nervous centres. We described the anatomical lesions which characterize that lesion, and the symptoms accompanying it, but we were not able to complete our subject in a single lecture; let us now then pass to the history of atrophy in other parts of the cerebro-spinal axis, including the pons varolii, the cerebellum, and the spinal marrow.

Atrophy of the Mesocephale

(the pons) has been observed, but this is a very rare lesion; indeed we are acquainted with only one case of this kind; it has been published by M. CRUVEILLIER, to whom we owe so many interesting facts connected with pathological anatomy. In the case now alluded to, M. CRUVEILLIER found the pons varolii considerably deformed; it was at least one-third smaller than we find it in the normal state; this diminished volume of the mesocephale coincided with a remarkable atrophy of the anterior pyramidal body on the left side. The subject of this observation was affected with hemiplegia; half the body was paralytic, although no other lesion existed to explain the modification of mobility than an atrophy of the annular pro-

truberance. The intellectual faculties were intact; the individual seemed capable of reasoning and judging as perfectly as most men, but a remarkable phenomenon manifested itself in the functions of the organ of language; the patient was quite dumb, incapable of uttering articulate sounds to express his wants, his desires, &c.; yet M. CRUVEILLIER remarks that before the first symptoms of hemiplegia had set in, this individual spoke perfectly well. In our former lectures you saw an impossibility of speaking connected with other lesions of the nervous centres; with congestion, hemorrhage, encephalitis, &c. Here the organic change was quite of a different nature, yet the symptom to which it gave rise was the same; another proof of what we have said on the frequency with which various lesions of the brain produce an identical derangement of function.

We have now touched upon the history of atrophy as it manifests itself in the cerebrum and mesocephale; but if we desire to attain an intimate knowledge of this lesion, and avoid all source of error in the manner of estimating its degree, or even sometimes its existence, we must remember that certain parts of the cerebro-spinal axis exhibit a marked difference of volume, according as we examine them at different periods of life. It is certain that the nutrition of the nervous centres is not the same in all individuals and at all ages; hence arises a difference in the

Form, Volume, and Consistence of the Nervous Centres

with which we should be acquainted, otherwise we may mistake a normal modification for an organic lesion of the brain. You will find this subject treated in a masterly manner, in the thesis of M. CAZAVIÈRE, to which we have already more than once alluded. You will there find it proved in the clearest manner that the volume of the brain differs as we examine it in the child, the adult, and the old person. In extreme old age the dimensions of the cerebrum are evidently modified; if we measure the diameters of the brain, in a person far advanced in life, at the level of the centrum ovale of Nicussens, we find it has lost in two di-

rections; the transverse and longitudinal diameters of this part are diminished by some lines; the brain is less than that of an adult, both in its thickness and its length. This difference of volume is not confined to the portion of the brain just mentioned. We find a reduction of bulk in various other important parts; thus the corpora striata, the optic thalami, the mesocephale, all these differ as we examine them in the young person, in the adult, and in the old man. The assertions we have just made are not mere ideas, vague and imperfect maxims, unsupported by proof; they are founded upon accurate and repeated measurements which have been made of these different portions of the brain, at different periods of existence.

There is, however, one circumstance connected with this subject so remarkable that we cannot pass it over without notice. While the various parts of the cerebrum increase from childhood to adolescence, from youth to full-grown manhood, and then diminish in advanced old age, the cerebellum is the only portion of the brain that does not undergo any change,—that remains the same in old age, as at any other period of life.

The reduction of the various diameters of the cerebrum in old age has also been established by another mode of investigation. M. DESMOULINS found that in individuals who had passed their seventieth year, the specific gravity of the brain is reduced by $\frac{1}{20}$ to $\frac{1}{10}$ from the average weight of the adult brain. ("Anatomy of the Nervous System in Vertebrated Animals," t. 11, p. 620.) This diminution of the normal volume is certainly connected with a change of function, and perhaps the time may come, when, better acquainted with the normal disposition of the several parts that compose the brain, and with the varieties of this disposition depending on individual conformation, the influence of age, &c., we may be able to explain several derangements of function whose causes are now involved in obscurity because the examination of the dead body does not reveal any appreciable lesion to which we can refer them. Let us now turn to

Atrophy of the Cerebellum

and spinal marrow. Atrophy of one or both these portions of the cerebro-spinal axis may be, as we have already seen it to be in the brain, less a true atrophy or diminution of substance once well conformed, than an effect of imperfect development. The reduced volume of the cerebellum or spinal marrow, then, depends, not on a lesion of nutrition, but on a diminished activity or arrest of the developmental nîsus. The first remark we have to make, in connection with atrophy of the cerebellum is, that in all cases where the cerebellum has been

completely absent, the hemispheres of the cerebrum are equally absent at the same time; the disappearance of one portion seems necessarily to bring with it the absence of the other. In cases of this kind the individual is totally incapable of living when separated from the mother-stock; malformation, carried to such a degree, admits of fetal life and no other. The child perishes of necessity a few hours after it has been placed in relation with the external world.

Cases have been observed where the cerebellum has been more or less absent, although the hemispheres of the cerebrum are developed in a normal manner; a case of this kind, which is perhaps unique in the annals of the science, has been published by Dr. COMBETTE; you will find it in the *Revue Médicale*, No. for April, 1831. Here we find the

Cerebellum completely Absent.

In its place nothing was found but a quantity of serous fluid contained in the meninges; on each side a peduncle, not larger than a pea, was attached to the corpora testiformia, all the rest seemed replaced by a serous sac. The pons varolii as well as the cerebellum was absent, and the individual in whom this remarkable lesion of the cerebro-spinal axis was observed, had attained the age of eleven years: thus you see that agenesia, or total want of the cerebellum, does not necessarily render existence impossible, provided the other parts of the nervous centres be well conformed. The individual may even live for a considerable length of time; the child here was near twelve years of age, and we have reason for considering the disease as congenital, for had it been acquired, had this absence of the whole cerebellum depended on an actual destruction of the nervous substance caused by an organic lesion, it is not probable the child could have survived so long.

What were the phenomena observed during life in this case of complete atrophy of the cerebellum and mesocephale? What effect did it produce on the intellect? What modification in the function of motion? The intellectual faculties were obtuse, though not to a remarkable degree; the answers slow and difficult; the whole countenance expressive of stupidity: in a word, the child, though not exactly idiotic, still showed a deviation of the mental powers. The motility was also modified; the power of motion was considerably weakened in the lower limbs, which did not possess their natural force and vigour: hence the child was unable to support itself with any firmness; it fell down frequently; the legs crossed each other during walking, and were moved in an irregular unsteady gait. At length the child was compelled to confine itself altogether to bed, and after some time was

unable to stir, even when lying in an horizontal position: thus you see the modification of motility consisted in a gradual abolition of motion: to this were joined epileptiform convulsions, which continued for some time, and finally carried off the patient. The sensation of the integumental covering was not modified in any way whatever. There was no increase of sensibility in the commencement, no obtuseness or diminution of feeling, even when paralysis was most complete: the senses also remained intact. The child could see, hear, and taste in a perfect manner. The functions of nutrition, of circulation, and respiration, were carried on without any notable disturbance; however, the child is mentioned as being weak and delicate in constitution; a circumstance which is conformable to the opinion of older physiologists, who have attributed to the cerebellum the power of regulating nutritive life.

In what manner were the generative functions influenced? This is a question of peculiar interest in the present case, because the cerebellum was completely absent. How then do we find the reproductive organs? Gentlemen, the uterus, the fallopian tubes, the ovaries; in a word the whole generative system was normally conformed; and, moreover, the child, who, if you remember, was only eleven years of age, showed a precocious tendency to the passions of her sex, and was given to masturbation.

The case we have just noticed is one of too interesting a nature not to dwell upon it an instant and consider what general conclusions may be deduced from the phenomena by which it was accompanied. They are the following:—*First*. That abolition of the intelligence does not necessarily attend complete absence of the cerebellum: the mental faculties may even be moderately developed. *Secondly*. The power of motion in the lower limbs was lost; hence we conclude that the cerebellum acts on the faculty of motion, and is more or less necessary to its perfect accomplishment. *Thirdly*. There was no paralysis of sensibility, and hence the general feeling is not connected with the cerebellum.

Instead of complete absence of the cerebellum, as seen in the case just detailed, we may have a

Simple Diminution of its Volume.

Sometimes this atrophy is general; all parts of the organ are generally reduced in bulk. In the case communicated by Baron LARREY to GALL, and recorded in the *Annals* of this latter author, the posterior portion of the cerebellum was considerably diminished. Here the lesion was accompanied by a change of form in the osseous parietes, and could be discovered by an external examination of the head. The genital organs were also imperfectly developed.

GALL moreover asserts, that in individuals who have been castrated, the external occipital region undergoes a diminution of volume. According to him this phenomenon is constant; however, we would not undertake to render ourselves responsible for its accuracy. In page 271 of his great work on the anatomy of the brain, you will find another example of coincidence of a diminution of one of the lobes of the cerebellum, with a diminution of the testicle in the opposite side of the body; but he does not mention whether this partial atrophy of the cerebellum was attended with any modification of the intelligence, of sensibility, or of motility. Carried away by the pursuit of a favourite idea, he sees nothing but the reproductive organs, and the lesions they may present, without occupying himself with the phenomena of still more important systems. Other authors mention cases of atrophy of one or both lobes of the cerebellum, yet they do not mention any change in the form or disposition of the genital organs, or any derangement in their function. Indeed it is certain that a congenital lesion of this part of the brain does not of necessity bring after it a lesion of generation.

In volume fifth of the *Archives Générales de Médecine*, p. 99, you will find a case of diminution of one of the lobes of the cerebellum, where the principal phenomenon was a loss of sight (and remember how blindness is connected with numerous lesions of this part of the brain); the individual was an idiot from birth, but did not present any modification of the sensibility, or any derangement of the generative apparatus. An interne, M. PÉROT, has also described a similar case of partial diminution of the cerebellar lobes, and here again we do not find any lesion of the genital organs.

Atrophy of the Cerebellum on one Side, and its Connection with Paralysis.

When treating of cerebral hemorrhage and its effects, we stated the curious, though well-established fact, that when effusion of blood takes place simultaneously into opposite sides of the cerebellum and the cerebrum (as, for example, into the left lobe of the cerebellum and right hemisphere of the cerebrum), the latter organ acts alone, seems to absorb the power of the former, and loss of motion occurs only on the side opposite the lesion in the cerebrum; on the other hand, when hemorrhage takes place into the substance of the cerebellum alone (the cerebrum remaining intact), we have constantly paralysis in the opposite side of the body. It is remarkable that the same phenomena occur in atrophy of the brain; thus, when the cerebellum is atrophied on the left side, and the cerebrum is, at the same time, diminished in volume on the right side, the former does not exercise any influence over the motions of the body; its effect

seems lost in that of the cerebrum, and we only find paralysis on the side of the body opposite the lesion in this latter portion of the nervous centres. We have examined the archives of our science to determine how far the law now announced, which is fully true with respect to cerebral hemorrhage, may be applicable to atrophy of the cerebellum. We have been able to discover only three cases of atrophy of one hemisphere of the cerebellum, coexisting with atrophy in the opposite hemisphere of the cerebrum, and in all these three cases only one side of the body was paralyzed—viz. that opposite the diminution of the cerebrum. One of these cases is recorded in volume fourteen of the *Archives Générales de Médecine*; it is also described in the thesis of M. CAZAUVIÈRE on agnesia; here the patient, a female, was affected with hemiplegia of the left side of the body; there existed in the brain atrophy of the left hemisphere of the cerebellum, and at the same time atrophy of the right hemisphere of the cerebrum. The second case was communicated to the *Anatomical Society*, by M. BODÉY, interne in the hospitals, and may be found in the annual report of the Society for the year 1830; this individual had hemiplegia on the right side, but, on the left, motion and sensation were intact; after death were found atrophy of the right lobe of the cerebellum, and, at the same time, atrophy of the cerebral hemisphere on the left side. Finally, our third case has been published by Mr. BELL, of the *Salpêtrière*, in the "Bulletin" of the *Anatomical Society* for May 1831; the subject of this observation was paralytic at the left side of the body. On examining the body, Mr. BELL found a considerable atrophy of the right cerebral hemisphere, and a diminution of volume, with flattening of the left hemisphere of the cerebellum. In this latter case, the individual was subject to apoplectic fits, and here let us remark the coincidence of epilepsy with a lesion quite different from that to which it is commonly attributed.

Atrophy of the Cerebellum alone, or conjoined.

Sometimes partial atrophy of the cerebellum exists alone, or is accompanied with an opposite state of another portion of the cerebro-spinal axis—viz. hypertrophy of the spinal marrow. M. HUTIN has given us an example of this kind in a journal, entitled, "*Nouvelle Bibliothèque Médicale*," t. 1, p. 34, January, 1824. Here the atrophy occupied the medullary centre of each lobe of the cerebellum; the white substance of the corpus rhomboideum did not exist, but that body was represented by a small pyriform, hard, brown-gray mass; the whole extent of the spinal column was hypertrophied; the chord, instead of leaving a considerable interval, as it does in the normal state, be-

tween the parietes of the vertebral cavity, completely filled it, and was, at the same time, indurated. What were the symptoms in this case? The chief phenomenon was an excessive sensibility of the whole skin. The patient was unable to stand upright, because the soles of the feet were too tender to bear his weight. When any part of the skin was touched, he gave signs of excessive sensitiveness, and even great pain, sometimes manifested by convulsive movements. At length the external world became, at every instant, a cause of pain; the unfortunate patient was unable to stir, or place himself in relation with a single object, and he at length died, wasted, exhausted, and literally worn down by painful sensations. This fact is a very remarkable one, and although the history of the case is given by M. HUTIN, with some details, yet we find no mention whatever made of the genital organs.

These are the principal facts we know connected with atrophy of the cerebellum; we may add, that the lesion may exist alone, or in union with atrophy of some other part of the nervous centres: thus, for example, it is not uncommon to find a diminished volume of the cerebellum coincide with atrophy of the spinal marrow. In some cases it is a true agnesia of the chord that we observe, not an arrest of development. Here we do not find any trace of the cerebro-spinal axis; the cerebrum, the cerebellum, and the spinal marrow, are all equally wanting; and the fetus, like those which we have already noticed, is incapable of sustaining an extra-uterine existence. This lesion is denominated "Amyelia," that is to say, a condition in which

The whole Spinal Marrow is Absent.

while a fluid, contained in a membrane, somewhat similar to the meninges, fills its place, and the nerves, which in a normal state are attached to the chord, seem to derive their origin from the rudimentary membrane. We find, at the same time, two different conditions of the osseous parietes which enclose the chord. In the first, the bones comprising the vertebral cavity are involved in the same lesion as that which has affected their contents, and we find the whole cavity open at its posterior part, or more or less imperfectly formed in the different regions; in the second case, the vertebral canal has attained its perfect degree of development, although the substance of the chord may be reduced to its maximum of atrophy; this is the same thing that we have already observed for the brain, where absence of the encephalon coincides with a well-formed skull, or with various lesions of the cranial parietes.

Imperfect Development of the Spinal Marrow.

Instead of being completely absent, the spinal marrow may present merely an im-

perfect development of one or more parts; the lesion is then called "atelomyelia," and may exist with a great variety of degrees. Thus in some cases we may find a greater or less portion of the spinal marrow divided, as in the fetus, into two lateral portions, from the absence of the gray substance that unites the two distinct chords, which, at an early period, constitute the spinal marrow. These two primitive chords or lateral portions form, by their approximation, a kind of furrow, which, at a later period, is transformed into a canal; this canal is really permanent in many animals, but in the human subject it is ordinarily obliterated at birth; however, it may persist, and then we find a canal of greater or less extent occupying the centre of the spinal marrow, commencing at the upper part, and seeming to form a junction with the fourth ventricle. In several cases the white or medullary substance appears to be perfectly well developed, and the lesion of nutrition affects exclusively the gray matter of the chord. Is it to a want of development that we should refer the presence of a canal in each lateral portion of the spinal marrow? GALL described these canals as existing in the normal state, but this is now found to be an error; however this may be, M. CALMIL saw the lateral canals in the bodies of two insane patients (*Journal des Progrès et des Institutions Médicales*); in one they existed all along the two sides of the chord; in the other it was impossible to follow them beyond the cervical region.

Instead of imperfect development, we may find a

Simple Diminution of the Volume of the Spinal Marrow,

without any change of its organization; this diminution may be either general or partial; when general, the lesion is very easily discovered. We see that the bulk of the chord is evidently reduced below the normal standard. M. MAGENDIE has recorded a case of this general atrophy of the chord, in which the lesion was accompanied by paralysis of the limbs. M. OLIVIER has also seen two examples of the same kind; in one, the volume of the chord was reduced to at least one half of its normal bulk; in the second, the whole chord was one-third less than it ought to have been. We have already remarked, that atrophy of the spinal marrow may be partial, occupying only a small portion, or a particular region, of the chord. You know that the portion of the nervous centres contained in the vertebral canal presents a kind of swelling (*renflement*), or

Protuberance at the Origin of the Nerves

which are attached to it. In cases of partial atrophy, one or more of those protuberances may be absent. Thus in a case observed by M. HURRI, the diminution of volume en-

gaged chiefly the lumbar renflement, which was reduced to the size of a common pen. In another case, cited by the same author, the brachial and lumbar protuberances were atrophied at the same time.

The Medulla Oblongata

(*bulba rachidienne*) may also be reduced to such a degree of smallness, as to seem wanting. M. CRUVEILHIER has described a case of this kind in a child, in whom the atrophy of the bulb coincided with an excessive density of this part; in fact, it presented almost a stony hardness; it was also accompanied by a conversion of nearly the whole substance into gray matter. We have already mentioned a case where atrophy of the cerebellum gave rise to loss of speech. In the case just mentioned a similar phenomenon was observed, or rather the child was affected with a great difficulty of speaking; she spoke excessively slowly; pronounced each word syllable by syllable. The power of the muscles that act on the larynx and pharynx was gradually abolished, and the child died from a difficulty of deglutition, joined to a loss of mechanical power of respiration; the muscles of the chest becoming finally implicated, respiration was rendered more and more difficult, and death took place in a state of true asphyxia. Indeed it may be laid down as a general rule, that atrophy of the spinal marrow in most cases produces a greater or less degree of paralysis. This loss of motion becomes gradually more extensive, more intense. The respiratory muscles are at length implicated in the general disorder; a difficulty of breathing sets in; the patient soon loses the power of dilating his chest, and dies asphyxiated.

Ramollissement of the Brain.

We have now studied two principal lesions of the nervous centres opposed to one another in their anatomical characters, but not so different as you might be inclined to imagine, in the functional modifications which they produce. We have concluded the history of hypertrophy and atrophy. We must now turn to another class of lesions, where the number of molecules remaining the same, they present a change of consistence, and become either hardened or softened. We have already touched upon several points intimately connected with softening of the nervous centres, for it is absolutely impossible to lay aside the consideration of ramollissement, to separate the pathological history and the symptoms of this affection, when we speak of various other diseases of the brain, as, for example, encephalitis, apoplexy, meningitis, &c. They approach so closely in certain points, that we cannot trace a faithful history of the one, without frequently introducing the other; however, we must study ramollissement

apart, if we desire to obtain a correct knowledge of its progress, symptoms, and termination. We must examine it independently of inflammation of the brain, of abnormal injection of the nervous pulp, independently of congestion and sanguineous effusion. In a word, we must study this important lesion by itself, apart from all others, and we shall endeavour to push our investigations as far as the actual state of medicine will permit, although we may occasionally have to repeat our observations, and employ, again, certain illustrations which you have already heard in a former part of the course. We will commence with ramollissement of the nervous centres in our next lecture.

CLINICAL LECTURES

ON

SURGICAL CASES,

DELIVERED IN 1836, AT THE

JERVIS-STREET HOSPITAL, DUBLIN,

BY

WILLIAM WALLACE, M.D., M.R.I.A.,

Surgeon to the Hospital, and to the Infirmary for Diseases of the Skin, Venereal Diseases, and Diseases of the Urinary and Genital Organs.

TETANIC SYMPTOMS, OR LOCKED JAW, RESULTING FROM INJURED NERVES.

GENTLEMEN,—I will commence this day's lecture by relating to you the heads of a very rare and interesting case:—

Philip O'Neill,

A tall muscular countryman, of a sanguineous temperament, and very blue eyes, aged between thirty and forty years, was thrown down, while leading a cart-horse over Essex bridge, when the wheel of the cart traversed his left leg a little below its middle, causing a fracture of both bones, with a communicating wound. He was immediately conveyed to this hospital, and being placed in bed, was treated according to the common practice.

No remarkable symptom occurred until the morning of the seventh day, when I was much surprised to find the bandages and splints greatly deranged. I was the more surprised at this, as up to that period the position of the limb had not sensibly varied from one visit to another, nor did the patient complain, at any time, of any uneasy feelings from position or bandages. Indeed, every thing had progressed in the most favourable manner, from the day of his admission, until that on which the displacement occurred. The wound had also begun to granulate, and even to cicatrize. Although I made strict inquiry, I could not

ascertain, from either nurse or patient, the cause of displacement. The bandages were re-adjusted, the limb was replaced in a proper position, and thus the patient was left, without any feeling any particular anxiety about his future state.

On the following morning, that is, on the eighth day after his admission, I found the limb again displaced; and I was informed that he had had a very restless night; that there were frequent spasmodic twitchings in the fractured leg; and that he found it impossible to preserve it during the night in the position in which it had been placed.

Such was the commencement of a series of as untoward symptoms as any I have ever witnessed. I shall not detain you with the daily reports of the case,— suffice it to say, that this patient, who had been advancing in the most favourable manner for seven days after admission, died four days after the spasms commenced in his leg; that is, on the eleventh day after the injury was received. The spasm gradually increased, from the morning of the eighth day, and in the course of thirty-six hours arrived at a state which it is difficult either to conceive or describe. Spasm is a bad, or insufficient, term to use. The limb was convulsed, and so constantly and so much, that for scarcely a minute could it be kept either by the efforts of the patient or by the pressure of assistants, firmly in any one position. Indeed, all such attempts seemed greatly to increase the convulsion. It was not only tossed to and fro, but occasionally raised with convulsive force, even some feet, from the surface of the bed. The bandages and splints could no longer be kept on. The wound in the soft parts (which parts had now altogether lost their healthy aspect and had become pale and glassy) as well as the fractured bones, appeared to be quite disregarded, so violent were the pains which the muscular actions produced. The lower fragment of the limb was thrown during the spasms into every possible position; with regard to the upper, it was knocked about like the loose arm of a flail used by a thrasher of corn, at one time being bent forwards, at another backwards, or to one side or the other, at angles of various degrees; and the bones at these periods protruded at the wound to a great extent.

The convulsions of the limb in a short time extended upwards, and then the muscles of the thigh co-operated with those of the leg, in producing the most violent and unrestrainable tossing or dashing about of the whole limb. At the end of the second day after the spasms had commenced, his countenance acquired a tetanic aspect, and he began to complain that his jaws were rigid, and that he could not swallow. Upon trying him with a little drink, I found that every time he attempted deglutition, a violent spasm took place in his throat, by which the

further progress of the liquid was obstructed. The situation of the poor fellow was at this period a source of the greatest distress to me. His symptoms were uncontrollable by any means devised, and his sufferings appeared to be great indeed.

On the fourth day, as if worn down by violent and constant pain and spasmodic action,—by exhaustion from absence of all sleep, and from want of nutriment, his countenance became pale and sunken, and his pulse tremulous, rapid, and weak. But the spasm in his limb and all muscular rigidity having at the same time ceased, and the power of deglutition having returned, I could not avoid having some hope, notwithstanding the degree to which he had been worn, that a favourable change was about to take place. On the following morning, however, my expectations were dashed, by finding that the poor fellow was no more; that he had died a few minutes before I entered the hospital, that is about twenty-four hours after the muscular system had become quiet.

I examined the body on the subsequent day, and have preserved this drawing, and the following notes of the

Morbid Appearances.

"The muscular system in general is rigid, and the muscles are marked, as if in a state of contraction. His countenance still presents a tetanic aspect. The pupil of the right eye is considerably more contracted than that of the left.

"*Right Leg.*—The upper portion of the

tibia is protruded one inch through the wound. This leg is some inches shorter than the other, and the state of the muscles and other parts is such, that the limb cannot be brought to its natural length. Having made an incision in the skin, on the outside of the fore-part of the limb, both upwards and downwards, so as to increase the extent of the wound, and having dissected a flap on each side, the bones are found to overlap nearly two inches. Having next removed the peronei muscles from the middle third of the fibula, the fracture of this bone is observed to correspond to the part where it is crossed by the fibular nerve, as it turns round to the front of the leg; and this nerve lies on the upper end of the lower portion of the fractured fibula, which end is remarkably sharp. The nerve in this situation, and for an inch or two above and below, is preternaturally vascular and much thickened, and the surrounding are soft parts infiltrated with blood, and diseased from suppurating having taken place among them. It is very evident (I have observed in my note of the dissection), from the manner in which the muscles covered and crossed the nerve and the sharp end of the fibula, that every time they contracted they must have pressed the nerve firmly against the bone.

"*Head and Spine.*—A quantity of a serous bloody fluid exists in the cavity of the arachnoid. The vessels of the membranes of the cerebrum, cerebellum, medulla spinalis, and oblongata, are very turgid. Great effusion between the pia mater and arachnoid—particularly on the superior surface of the hemispheres. An effusion of blood on the outside of the sheath of the spinal marrow, nearly opposite to the middle of the chest. The plexus choroides livid from congestion; some reddish serum in the ventricle; the substance of the brain very firm, and over-vascular.

"*Abdomen.*—The gall-bladder contains much bile. The capillary vessels of some of the small intestines are in a state of congestion. The intestines are, in general, irregularly dilated and contracted, the transverse arch of the colon, and the cæcum, are much dilated, and the end of the ilium and several parts of the large intestines are irregularly contracted."

Was this a Case of genuine Tetanus or not?

In many points of view it strictly resembled tetanus, but not in others, provided we confine our views of tetanus within the bounds placed by some to the characters of this disease—or, in other words, if we deny the name of tetanus to every disease which does not present certain symptoms, in general considered pathognomonic. The period at which the spasmodic symptoms set in, viz. on the seventh day, and when the wound was granulating and even cicatrizing, is the

period and the state of the wound at which traumatic tetanus in general commences. The permanent rigidity of the jaws, the difficulty of swallowing, and, above all, the peculiar cast of countenance, were also in a high degree characteristic of tetanus. On the other hand, the manner in which the spasms commenced—that is, in the wounded limb, their gradual extension to the head, the absence of pain in the epigastric region, and of rigidity in the muscles of the abdomen, as well as of any decided spasms of the trunk, are all phenomena unlike what we commonly observe in genuine tetanus. The cessation of spasms, and the restoration of the power of deglutition, so long before death, are also symptoms which I have not observed in true tetanus. Nor have we any good reason for supposing that in this disease the cause of mischief is seated, as was evidently the case in the present instance, in an irritated or injured nerve, or that there exists such a state of the brain as was on dissection observed in this case. Such are the reflections which occur to me, when I compare the case of O'Neil with the numerous cases of ordinary tetanus which I have witnessed.

The case of Hagerty, noted in the hospital case-book, seems to me to have many points of analogy with the case of O'Neil, and what is important to us on the present occasion, it furnishes those symptoms which have been considered pathognomonic of tetanus, viewing this disease in the common manner, which were wanting in the case of O'Neil; while O'Neil's case affords symptoms, considered equally characteristic of tetanus, which were wanting in the case of Hagerty. I shall read you the heads of

Hagerty's Case.

This patient, who was a labourer, aged fifty-four years, was admitted with the soft parts covering the left great-toe, much contused and torn, and with a wound of the same shin, or of the front of the leg. These injuries had been caused by the limb having been jammed between a lamp-post and a cart. He had lost a large quantity of blood, and he complained much of pain extending up the leg. On the ninth day, when the wounds were suppurating and granulating healthily, the nitrate of silver was applied, by my directions, to some exuberant granulations on the skin. This application seemed to cause great pain, evinced by loud and repeated cries.

Tenth day. He still complained of pain, and he described it as shooting from the front of the foot and leg along the calf, ham, thigh, and back, up to the neck.

Eleventh day. He had several spasmodic twitches in the limb, which extended up the trunk.

Twelfth day. The spasms in the limb became more frequent and severe, and he

complained of rigidity of his jaws, with inability to open them to their full extent. During the general spasms, the head and trunk were drawn backwards.

Thirteenth day. Same symptoms continued, and rather increased.

Fourteenth day. The jaws were much more fixed, and the muscles of the neck and abdomen were very rigid. On this day he had frequent general spasms, commencing in the limb.

Fifteenth day. He was as on the 14th, with the addition of pain in scrobiculo cordis.

Sixteenth day. Stiffness of jaws was increased, but the spasms were milder since yesterday. Slight drooping of the upper eyelid; pain in scrobiculo cordis less. Salivation commencing, from the calomel and Dover's powder, which he had been taking since the twelfth day.

Seventeenth day. Rigidity of neck diminished. Rigidity of abdomen nearly the same. Had four mild spasmodic paroxysms since yesterday.

Nineteenth day. Spasms much milder and less frequent; scarcely any rigidity of the muscular system; copious perspirations. Complaints of sickness of stomach, or of what he calls a water-brash.

Twentieth day. Occasional, but very mild spasms. Rigidity of jaws, neck, and abdomen, diminished.

Twenty-fifth day. No spasms; no muscular rigidity. Suffers much from profuse salivation. Was discharged cured on the 16th of May, about six weeks after admission.

The Symptoms, if combined, in the foregoing Cases, are those of Genuine Tetanus.

You may observe, that this case presented, as I have said, certain characteristics of tetanus, which were wanting in the case of O'Neil. Thus, there existed in Hagerty's case, abdominal rigidity, pain in scrobiculo cordis, and convulsions of the trunk, during which the body was bent backwards; while certain symptoms were wanting which were found in the case of O'Neil, and which are considered equally pathognomonic as those which did exist. Of these, the most remarkable was the absence of the tetanic countenance, which was strongly marked in O'Neil, and was ~~marked~~ in Hagerty simply by a drooping of the eyelid, and this observable only on the ~~sixteenth~~ day, and perhaps not deserving of being considered expressive of a tetanic countenance.

When the case of Hagerty was passing under my observation, the impression was made on me, that the symptoms originated in an inflammation or morbid state of the peroneal nerve, as in the case of O'Neil; that this inflammation had commenced in the nerve so low as in the dorsum of the great-toe; that some of its branches, which

passed through the wound on the shin, had been irritated by the application of the nitrate of silver; that the inflammation or irritation had subsequently extended along the sciatic nerve, through the popliteal space, and up the thigh to the spinal marrow; and that thence resulted the more general muscular affections.

Now it is evident, that if we combine the symptoms of the cases of O'Neil and Hagerty, we shall have all those that occur in the most genuine forms of tetanus. We shall, however, have also

One most important Symptom present, which does not exist in ordinary Tetanus,

so far as I have had an opportunity of witnessing the disease for more than fifteen years in this hospital, so famed for accidents. I allude to a spasmodic affection of the muscles of the part injured, and it was with this symptom that the general spasm commenced in the cases of O'Neil and Hagerty; whereas rigidity of the muscles of the jaws, or of the back of the neck, without any pain or convulsion of the limb, however severe or trifling the wound may have been, is the almost uniform mode of commencement of what is called genuine tetanus. In support of this fact, let me recall to you from the case book of the hospital the heads of two or

Three Cases of Genuine Tetanus.

Case 1—Gannon, a strong and healthy child, aged three years, was admitted with a wound four inches long, which penetrated through the integuments, on the outer side of the knee-joint. The joint was not injured. A quantity of dirt and gravel was imbedded in the wound. There did not exist any apparent constitutional disturbance.

Third day. Suppuration commencing.

Seventh day. Wound granulating at its upper angle, sloughy at its inferior end. The child looks pale and sickly.

Eighth and ninth days. Restless and peevish.

Tenth day. Unable to open his mouth, and when he attempts to take a drink, a slight convulsion ensues, with a tetanic expression of countenance. The power of moving his lips, however, continues perfect, and when he is at rest, his countenance has not any tetanic appearance. No rigidity of muscles of either neck or abdomen.—*Evening.* His countenance has, even when at rest, the tetanic aspect. There exists a rigidity of the muscles of his neck and abdomen: and when a convulsion is excited by any attempt to drink, the head is drawn back, and, even when quiet, he is unable to bend it forwards.

Eleventh day. He had several convulsions during the night, when attempting to drink, but was quiet when not excited. His paroxysms became more frequent and more severe during the day.—*Evening.* He has had

two violent paroxysms. One which he had at ten o'clock has been thus described in the case-book. His body is so violently bent backwards, that his occiput and heels alone touch the bed, his trunk and lower limbs forming an arch. All the muscles of his neck, back, upper and lower limbs, are hard and rigid. All the features of his face are violently contorted. His eyes are turned upwards and inwards. Subsequently, his breathing became laboured and stertorous, and afterwards so faint, that, joined with a state of insensibility, it was supposed he was dead. After a minute or two, however, he recovered, turned on his side, and called to his mother for drink.

These violent paroxysms recurred with an interval of an hour, until about three o'clock in the morning, when he expired.

Case 2.—Scully, aged eleven years, received a deep punctured wound in the hollow of the sole of his right foot, caused by leaping from a height on a thick blunt hook. He leaped from an ass-cart on the pavement to fasten the trace, which had become loose by the hook falling out on the ground, and it was on this hook he leaped.

Second, third, and fourth days. Accelerated pulse, restlessness, pain in the head, perspirations, foul tongue, sick stomach.

Fifth, sixth, and seventh days. Seemed to be progressing to recovery.

Eighth day. Frequent yawning, of which he himself complained.

Ninth day.—In the morning complained of stiffness in the back of his neck, and difficulty of deglutition. No inflammation in his throat to be observed. No pain in fancies.

—*Mid-day.* Muscles of jaws rigid. Considerable difficulty of opening his mouth; pain felt in the epigastrium, when he attempts to sit up. Muscles of abdomen slightly rigid. The tetanic aspect exhibited in his countenance by a wrinkling of his eyebrows and forehead, and by a divarication of his nostrils.—*Evening.* Irritability of stomach. Rejects his drink. Very frequent convulsive paroxysms; each lasts, however, only a few seconds; during these, the muscles of the back are contracted suddenly, and, by a quick jerk, throw forward the abdomen. Each paroxysm is attended also by a quick expiration, and an increase of pain, which he refers to the epigastric region, and which elicits a groan. During the intervals of the paroxysms, the rigidity of the muscles of his abdomen and neck continues. He frequently asks to be placed sitting up in bed, and when the attempt to raise him is made, he becomes from head to foot as rigid as a board. When he wishes to take drink, which he can do only while sitting, he is unable to bend his head forward, and asks impatiently his father to bend it. His skin in general is moist, and his face and breast are in a state of perspiration. Pulse 120.

Tenth day.—He had a paroxysm every five or six minutes during the night, and, on one of these occasions, the opisthotonos was so violent, as to raise him almost entirely out of the bed. The least exertion he makes, on turning him, or asking him a question, or even any sudden noise, produces a paroxysm; and, independently of any excitement, he has one every three or four minutes, but each lasts only a very few seconds. He complains of having bitten his tongue, and often cries out with pain, which he refers to his loins. He seems occasionally to drop for a minute into a doze—his eyes half closed, but, in an instant, he awakes with a sudden jerk. His stomach is very irritable, and occasionally rejects its contents.—*Evening.* Paroxysms more frequent—during five minutes he had no less than ten; his pulse during the paroxysm is 138, in the interval 108. Bowels confined; makes no mention whatever of his foot. The wound is nearly healed.

Eleventh day.—Is extremely weak; paroxysms have been very frequent during the night, but they were not so violent, nor did he cry out with them so much, as before. Complains of pain in his belly, and back of his neck. Has a strong desire to drink, but says there is a stoppage in his throat. Complains of itching in his face. His fingers are not engaged during the paroxysms, nor are they rigid in the intervals.

Not to detain you longer with particulars, this child died in a convulsion, on the fifth day from the commencement of the tetanic symptoms, and some time previous to death, great dyspnoea, with delirium, set in.

Case 3.—Sadleir, aged 30, a strong and healthy labourer, had his right hand jammed between two beams of timber, in such a manner, as to cause the phalanges of the three fore-fingers to be over-extended or flexed backwards, so as to produce a compound dislocation of their articulation with the corresponding metacarpal bones. The flexor tendons were torn across, where they cover the joints, and the cartilaginous surfaces of the bones were visible. The metacarpal ends of the phalanges were thrown on the palmar aspect of the metacarpal bones. There was a wound between the thumb and fore-finger, about half an inch long, through which a mass of muscular flesh was protruded in such a manner, that it seemed to be girt by the orifice of the wound. The bleeding was trifling. He complained much of a sense of numbness, but of no pain. The parts were easily restored to their natural position, and the injury appeared then so trifling to him, that when the propriety of removing the fingers was hinted at, he expressed himself so strongly against an operation, that it was not further spoken of.

Third day. Suppuration with much tumefaction.

Fourth day. Increase of discharge, which is rather thin. The skin of his hand and forearm presents a slight blush of red as far as the elbow.

Fifth day. Matter formed on the dorsum of the hand, in the course of the tendons, and discharged by an incision.

Eighth day. Complained of soreness and stiffness of the jaws and throat. His tonsils seemed inflamed and enlarged. In the evening he complained of pain in the epigastrium.

Ninth day. Stiffness and rigidity of his jaws, and inability to open his mouth increased. Profuse and general perspirations. Has had two convulsive paroxysms; pulse 102; complains of no pain.

Tenth day. He expired this morning, immediately after a spasmodic paroxysm. It was reported that he had had a spasm, almost every hour, from the evening of the ninth day, until the morning of the tenth; that they became more and more severe; that during the paroxysms his face became almost black; that all night the muscles of the back of the neck and of the abdomen had been in a state of great and constant rigidity; that at first the spasms had lasted about one minute, but subsequently not less than a minute and a half.

En passant, I wish to observe, that this was one of the most rapid cases of tetanus which I have ever witnessed, and the violence of the symptoms was by no means proportioned to the rapidity with which the disease ran its course. The patient was kept under the influence of tartar emetic from the first appearance of the disease, until his death, and from what I observed in this case, I would never again think of trying that remedy.

In none of these cases, and if necessary I might detail to you many others, did the wounded limb attract attention, either by pain or spasm. Were there no other circumstance than this, to distinguish them from such cases as those of O'Neil and Hagerty, this alone would be quite sufficient; and if the latter cases are to be viewed as examples, they should be considered to form a variety distinct from the former.

There has been much discussion respecting what is

The Wounded Tissue which is the immediate Cause of Tetanus.

You are all aware that the opinion prevails that this disease is produced by wounds of tendinous parts. Are not such cases as those of O'Neil and Hagerty highly suited to cast light on this obscure point in pathology? For example, if the irritation or inflammation of a large nerve is capable of influencing the centres of the nervous system in such a manner as to cause a series of symptoms almost identical, if not entirely

imilar, with those of genuine tetanus, we are prompted by analogy to infer that it is in some such way that ordinary tetanus is produced. Nor does our incapability of discovering in this disease organic lesions in the nerves of the injured parts, authorize us to conclude, in our still imperfect knowledge of minute structure, that no organic lesion exists. And if the immediate cause of tetanus be seated in the spinal portion of the nervous system, as the inquiries of my friend Dr. REID of this city, and, subsequently, of others, go to prove, an additional argument will thereby be afforded for inferring that it is an injury of the nervous tissue that gives origin to tetanic disease, and not of either the tendinous, or, as some suppose, for example the late Dr. PARRY, of the muscular.

It is remarkable that the effects which we know to arise from an irritated nerve, are always more severe a few days after the injury has been inflicted, than immediately on its receipt. This corresponds with the phenomena presented by tetanus. For the symptoms of this disease rarely indeed commence for some days after the infliction of the injury which causes it. In the cases of *O'Neil* and *Hagerty*, the nervous symptoms began, as I have already observed, about the same time, and in the same state of the wound, as we would have expected tetanus. Thus in *O'Neil*, the first symptom of nervous mischief was on the eighth day, and in *Hagerty*, on the tenth day, while in the cases of *Scully* and *Sadler*, they commenced on the eighth day; and in the case of *Gannon* on the tenth day. This points out a close relationship among these affections.

In the memoirs of Baron LARREY, you will find many facts, which, in my mind, demonstrate the probability that a local injury of nerves is the immediate source of mischief in tetanus. He often noticed, for example, a remarkable connection between the character of the tetanic symptoms and the situation of the wound which caused them. He observed, both in Egypt and Germany, that when the wound involved nerves in the front of the body, the symptoms were cinprosthotonic, and when those on the posterior part, opisthotonic; but that when both classes of nerves were injured, complete tetanus ensued. It was also a remark made by him, that wounds in the course of the larger nerves were very often followed in the climate of Egypt by tetanus. But what is still more to the purpose, you will find on record some cases which are really as cases of tetanus, in which there was an injury of a nerve more or less similar to that which occurred in the case of *O'Neil*, and probably also in that of *Hagerty*.

Mr. LISTER, one of the able professors of surgery in the University of London, has given us, in the *Edinburgh Medical and Surgical Journal*, a case of tetanus in which he

performed amputation with temporary relief, and when he examined the amputated limb, he found that the branch of the median nerve going to the thumb was torn two-thirds across, and its extremity inflamed and thickened for nearly an inch. He also, subsequent to the death of the patient, found about two inches of the same nerve at the bend of the arm, very vascular, but without effusion or thickening of the envelope.

Dr. HENNAN has, in his *Military Surgery*, mentioned that he found the radial nerve thickened, and a small splinter of bone sticking in it, in a man who died of tetanus.

Baron LARREY has recorded the case of the son of a general officer who died of tetanus, consequent on amputation; and upon examining the stump, the median nerve was found included in the ligature with the artery. He also mentions a case in which he suspected that tetanus was caused by a ligature on the crural nerve. He removed the ligature, canterized the nerve, and the man recovered.

You will also find, in the first volume of LALLEMAND'S *Researches on the Brain and its Appendages*, the case of a soldier, aged about 38 years, whose subclavian artery was tied for aneurysm. When the ligature was drawn tight on the vessel, the patient experienced great pain in the neck. This pain diminished the next day, but on the fourth and fifth days it became very severe. On the seventh night, there was "perte de connaissance," particularly of the inferior limbs. (LALLEMAND conceived that the convulsions of the upper limbs had been prevented by the bandaging.) Immoveable pupils, short and frequent respiration, small and irregular pulse. On the eighth day the head was drawn back by spasms, and death took place in the evening. On dissection, it was found that the ligature on the subclavian artery had included the branch of the brachial plexus, which comes from the third pair. An abscess was found in the posterior lobe of the left hemisphere. The vessels of the cerebral substance, and those of the pia mater, were preternaturally developed, and the ventricles contained some reddish serosity.

There are probably other cases of an analogous kind on record, which I have either not read, or which may have escaped my memory. Those which I have mentioned are, however, quite sufficient, in connection with the two which we have ourselves witnessed, to authorize us to conclude that there does exist a form of tetanic disease, which is in very close relation with, if not entirely dependent on, an injury of a nerve. May we not, as I have already said, consider such cases as forming a peculiar variety of tetanus? This seems to me to be the more correct way of considering this subject.

When we reflect on the different results which have followed the same kind of treatment in different cases of tetanus, I think we are compelled to believe that authors have included under this term many forms of disease which differ so essentially from each other, as to require dissimilar modes of treatment. This would certainly be a natural way of accounting for the discrepancy which exists among reported cases.

Of the various Modes of Treatment

adopted, there are few that have afforded more discordant results than that by amputation. It is, in general, now never thought of; yet LARREY seems to have obtained advantage from the practice, and even from the division of the nerve leading from the injured part. I confess, that when I reflect on the facts connected with this subject, I am disposed to conjecture that the cases of tetanus in which this mode of treatment will be beneficial, are such as those we have been considering; and I have scarcely a doubt on my mind, that, if amputation had been performed at a sufficiently early period, or the irritating extremity of the fibula removed, or even if the injured nerve had been divided in some part of its course, between the spine and the seat of injury, the life of O'Neil might have been saved.

Should further investigations lead to the conclusion that there is a peculiar form of tetanic disease, which has for its cause an injury of a large nerve, and that these are the cases in which an early amputation, or the division of the nerve between the injured part and the brain, is likely to be useful, our attention will be directed to distinguish such cases from others; and I am induced to believe, from what I have seen, and for the reasons already advanced, that the situation or part in which the spasms commence will be a powerful assistance, as a

Means of Diagnosis,

if not of itself sufficient. It is to be regretted that in the recorded cases I have mentioned, and in which the symptoms were connected with an injured nerve, no notice has been taken as to the exact manner or situation in which the spasms commenced. They do not, therefore, afford us the assistance on this subject which we might otherwise obtain from them. RICHERAND says, that he has sometimes noticed in wounds which threaten tetanus, that a persevering extension of the limb during sleep often manifested itself before other symptoms were observed. Do such cases belong to the class of tetanic affections which arise from injured nerves of large size? To the same class most probably belong also three cases of tetanus recorded by Sir GILBERT BLAKE, in two of which the symptoms affected the side of the body in which the wound was

situated, and in the third, they were accompanied by a trifling and rather agreeable sensation in the part.

If there exists a form of tetanus dependent on a laceration of a nerve, and if such form calls for amputation, or the division of the injured nerve, or the removal of the irritating cause, it must be clear, from the facts unfolded by the case of O'Neil, and by the cases recorded by LALLEMAND, that such cases will not be benefited by such operations, unless they be executed early, or before the disease has extended so far as to cause inflammation of the central portions of the nervous system. This precisely corresponds with the rule of practice given by LARREY; he advises that they be performed before inflammation commences.

Mercurial treatment has often been supposed to be useful in tetanus; and in the case of Hagerly there could be little doubt, from the close connection observed between the improvement of his symptoms and the commencement of salivation, that material service was obtained from the action of the mercury. Will further experience sanction the conclusion, that it has been in cases of tetanic disease arising from the injury of a nerve, that mercurial treatment has been serviceable?

In conclusion, and as my only apology for having occupied so much of your time with this lecture, I have to observe, that should it turn out, that it is in cases of tetanus from injury of a large nerve, that advantage is to be expected from mercury, or from amputation, or from the division of a nerve, or the removal of causes of irritation; and that the diagnostic symptoms, which I have laid down, are sufficient to distinguish these varieties of tetanus from others; it will thus be admitted, that a step has been achieved in the study of the symptoms and in the treatment of a disease, respecting which every thing seems to be, as yet, in confusion. The facts which I have witnessed those which are on record, and the reflections which both have created in my mind encourage me greatly to endeavour on every opportunity to ascertain the distinguishing peculiarities of each case which may present itself to me. In short, I feel convinced, that one cause of failure in the treatment of this disease, has arisen from our great neglect of its varieties.

ST. GEORGE'S HOSPITAL.

CLINICAL LECTURE

ON A CASE OF

RANULA.

Delivered in the Session 1835-6.

BY MR. WALKER.

GENTLEMEN,—It is my intention to bring under your notice this morning the particulars of a very interesting case which presented itself a short time since amongst the out-patients under my care. It was one of sublingual tumour, occupying the usual situation, but differing in some points from that form of disease which is known and described to you under the name of "Ranula."

The patient, Elizabeth Holloway, an interesting healthy-looking girl, about 19 years of age, perceived for the first time, about two years ago, that a small tumour was growing under her tongue. At this time it was no cause of pain or inconvenience, either in swallowing or speaking, nor would she even have been aware of its existence had not her attention been drawn to it by a female relative who had herself a few years previously suffered from a tumour occupying the same situation, and who was, therefore, more sensible of a slight hisping in the speech of the patient. A few months since, the tumour, from having remained quiescent, began gradually to increase in size, and materially to interfere with the functions of the parts in the vicinity of which it was situated. Swallowing caused her inconvenience rather than pain, and her voice, from its natural soft tone, changed into a note much resembling that of a frog's croak. It is, in fact, from this peculiarity that the disease has obtained its name of ranula. Her voice was thick and reedy from the pressure caused by the tumour (which had now attained the size of a pullet's egg), upon the superior portion of the larynx. The living mucous membrane of the mouth moved easily over the surface of the tumour, and there appeared to be no impediment whatever to the natural flow of saliva. You may remember that at about this time I introduced a blunt probe into the ductus Whartoniensis. It did not enter into the tumour, but passed downwards to its under surface, a circumstance which led me to prognosticate that the tumour was situated in the cellular structure under the tongue, and altogether unconnected with and unattached to the sublingual ducts.

She was extremely anxious to have the tumour removed, and I accordingly operated

in the following manner:—She was placed in a window fronting the light; the head was thrown backwards and supported; the motions of the tongue were checked, and commanded, by its apex being pressed against the bony palate of the roof of the mouth. Whilst in this position, the mucous lining of the mouth, which was kept on the stretch over the tumour, was divided in that situation by the lancet, and the cyst of the tumour was exposed. That was next divided, and a considerable quantity of thick atheromatous matter immediately escaped. On examination I found the cyst to be much firmer and denser in structure than is usually attained in these cases, and of sufficient tenacity to bear some firm manipulation. I secured it by a pair of common dissecting forceps at the opening previously made through the mucous membrane, and dissected it out with a flat aneurysmal probe. At its inferior position it was attached to the mucous membrane by a small peduncle, of about the size of a crow-quill, which was divided by the scissors. The operation proved troublesome, from the escape of the contents of the cyst, and the inconvenient and awkward situation which it occupied, as the cellular structure at this part is loose, and but little force is required to detach or separate it from a tumour of this kind, and I should therefore always advise you to effect this by an instrument similar to the one which you saw me use—viz., a flattened aneurysmal probe. The use of a knife in operating on these parts is dangerous, from the chance you run of wounding any of the sublingual vessels, which are of a large size, and the little control which you can have over the movements of your patient, for I can safely promise you that you will find few so quiet and tractable as this patient was. After the tumour was removed, the situation it occupied was carefully examined, and finding that the whole of the cyst had been removed, and that there was no hemorrhage from the part, I ordered her to rinse her mouth out frequently with warm water, and to take a pill of calomel and antimony at night, and a senna draught on the following morning, and at her very urgent request I allowed her to return home to her friends in the neighbourhood of Coldbath-fields.

Thus much of this case, gentlemen, you were most of you enabled to witness, and I regret the more that I could not prevail upon the patient to remain for a few days in the house, as it is during that period that the most important part of the treatment in such a case as this is called for.

* On examining the tumour previous to its being placed in the Museum in Grosvenor-place, we found the above remarks fully verified.—*Rep. L.*

Twelve hours after the operation she was attacked with great difficulty of breathing and deglutition, which continued unabated until I saw her on the following day, about twenty-four hours after the operation. I found her tongue enormously swollen, rendering it impossible for me to examine the throat. Every attempt which she made to swallow produced symptoms approaching those of strangulation, her face was flushed and turgid; skin hot and parched; pulse 120, rapid and thready; and her countenance expressive of the greatest anxiety. Now, with symptoms such as these it may frequently be requisite, in full, strong, and plethoric persons, to abstract blood largely from the system, and produce a decided impression at once, but in more delicate subjects topical bleeding will be found quite sufficient to answer this purpose; but even this you must do effectually, and check the inflammatory action at once. Twenty-four leeches were ordered to be applied to the throat, followed by a linsed meal cataplasm; six grains of calomel and five grains of James's powder were administered immediately, and were followed in four hours by a strong senna draught. The leeches were re-applied on the following morning, for although the painful sensation of suffocation about the throat was materially relieved, there still remained sufficient difficulty in deglutition and respiration to render their re-application a matter of prudence. She took the infusion of roses with sulphate of magnesia and diluted sulphuric acid every six hours, for a few days, when she continued to go on without any further let or hindrance to her perfect recovery.

The Symptoms which sometimes follow an Operation on Parts near the Throat,

where there is required any force or violence to separate the morbid from the healthy structures, are frequently of a distressing, and sometimes of an alarming character, and the consequent restorative inflammation, if I may use the term, which is naturally set up in the part for the reparation of the injury, frequently affects the surrounding important organs of respiration and deglutition, in the manner which I have already described to you occurred in this case; the same symptoms occurred in the patient M'Donald, after I had removed the tumour, situated externally, near the region of the parotid gland, and dipping downwards and forwards under the angle of the jaw; but they were speedily and effectually relieved by the same means being employed as above detailed. In the treatment of these cases you must be active at the onset, and attack them vigorously; you must not be satisfied with putting on six or eight leeches, but you must apply a couple of dozen, and repeat the application of them very soon, if you do not find the symptoms speedily and

completely relieved; and, as I before told you, if your patient be young, vigorous, and plethoric, you may, with great safety and relief to him, take a large quantity of blood in a phlebotomy from the arm, and afterward repeat the depleting effect, by the abstraction of blood locally, bearing always in your mind the great importance of these organs in the animal economy which are to be thus preserved and kept free from inflammatory action.

The Disease in the present Case

(Holloway's) did not partake of the ordinary character which is usually obtained by the sublingual tumour denominated ranula, but came more properly and particularly under that class of tumours which is denominated encysted. It was unconnected with the sublingual duct, and was situated in the loose cellular tissue beneath the tongue. It is not very uncommon to meet with encysted tumours occupying this situation, the cyst, however, is generally found to be very thin and attenuated, and the contents are most commonly of an albuminous glairy character, resembling the white of an egg. Encysted tumours of this nature are frequently met with in other parts of the body; I have removed them from the labium pudendi, and from the inner surface of the lips; they seem to occur and form under surfaces covered by mucus membrane, and where glandular apparatus abounds, more frequently than in other parts. They seldom admit of removal by dissection, from the extreme delicacy of their texture, this circumstance rendering it very difficult, and almost impossible, to separate them from the surrounding parts without leaving some portion of the cyst behind; and when this happens, you may be pretty sure and certain that the disease will return again. The method of proceeding where extirpation is impracticable is the following; you must proceed in the first steps of the operation as I have already explained to you;—freely divide the mucous membrane of the mouth and the cyst itself, empty the cavity of all its contents, and allow all bleeding to cease. Then wipe out the cavity with a piece of lint, and rub over the whole of its inner cavity with a piece of caustic potash, so as completely and entirely to destroy the whole cyst. After this is done, you may if you please wash out the patient's mouth with some vinegar, which, by decomposing the caustic, will check its further action on the surrounding parts. The slough of the cyst will separate in a few days, granulations will spring up from the bottom of the cavity, cicatrization will take place, and the cure will be thus effected.

I will now detain you a few minutes by explaining to you the

Course, Nature, and Treatment of Ranula, that disease I mean which is more commonly

denominated "ranula." This, like the encysted tumour, generally occupies some part of the cellular space under the tongue, and between the rami of the lower jaw, and is gradual in its growth, and has a semi-transparent appearance. The origin of this disease can be dated from obliteration of the common orifice of the sublingual and submaxillary ducts; the discharge of saliva is thus checked and prevented, and there is a consequent accumulation in the duct, the secretion becomes inspissated, and mixed with the mucus poured out by the lining membrane of the canal, and in this way a tumour, sometimes of considerable magnitude, is produced. When it is practicable, some authors have recommended the introduction of a small probe into the mouth of the duct, and treat the constricted orifice by gradual dilatation, as in the cases of strictures of other mucous canals. In this way I have known the distended cavity to have become emptied, and a free exit established for the subsequent secretion of mucus to escape. When the orifice of the duct cannot, however, be re-established in this manner, the treatment of it by caustic potash is the best; or, if the tumour be a very large one, the excision of a portion of the mucous membrane, with the parietes of the cyst, may be substituted for simple incision. This is the method which I should advise you to adopt, but other plans besides these have been recommended. The nitrate of silver has been proposed, and will, I have no doubt, often succeed; its object is precisely the same as that of the caustic potash, that of destroying the cyst, but in this respect I rather believe that it is less to be depended upon than the kali purum. There is another mode of treatment which is sometimes adopted in these cases; it is one, however, which I feel it to be my duty strongly to caution you against - it is the introduction of a seton. A skein of silk, or part of one, is drawn through the substance of the tumour, and tied in a knot closely under the tongue. The object of this method of treatment is manifest; it is that of producing inflammation and consequent obliteration of the cyst. This is a very nasty mode of proceeding, independent of its being a very dangerous and inefficient one; I have seen it productive of great inflammation in all the surrounding parts, and attended with the severe symptoms which I enumerated to you in a former part of this lecture as occurring in this case, and I have never seen it cure the disease. The degree of feverish excitement and general disturbance of the whole system which I have seen attend this mode of treatment, would prevent my ever having recourse to it.

Besides the accumulation of saliva,

Earthy Deposits in the Salivary Ducts
under the tongue, principally formed of the

phosphate of lime, are often met with; they seldom produce any inconvenience, nor do they interrupt the flow of saliva, and perhaps they are not discovered until they become inconvenient from their size and magnitude in the mouth. I have removed several, and one a short time since from a girl who presented herself among the out-patients. This was of a larger size than any which has previously fallen under my notice, it was about the size of a horse-bean. There is of course no reason why they should not attain a much greater size than this. They may be removed by a very simple process. You have nothing to do but to divide the membrane of the duct with the point of a lancet, and you can then easily dislodge the calculus by means of the edged extremity of a probe; it will generally escape without any assistance, after the division of the parts. It, however, sometimes happens that the presence of a calculus in the ductus Whartoniensis is productive of considerable inconvenience to the patient, and escapes from the duct without operation. This occurred in a case (the preparation of which I now show you) which was given me by a friend some short time since with the following history. The patient had suffered for several years from pain and uneasiness at the inferior surface of the tongue, and from a painful spasmodic affection of the miglo-hyoideus muscle, the stone was discharged during the night from the duct, and all her former painful sensations immediately left her.

ON THE
LAWS OF SICKNESS,
ACCORDING TO AGE,

EXHIBITING A DOUBLE COINCIDENCE BETWEEN THE LAWS OF SICKNESS AND THE LAWS OF MORTALITY.

By T. R. EDMONDS, Esq., late of Trinity College, Cambridge.

THE law of mortality of any population, consists in the expression, for successive ages of life, of the number dying out of a given number living. Similarly, the law of sickness will express the number constantly sick at any age, out of a given number living at that age. The law of sickness, as will presently be seen, admits of a simple and precise definition; but it does not immediately inform us how many individuals at a given age are yearly attacked by sickness. This law has regard to the duration, and not to the number of cases of sickness suffered by a given number of individuals.

There have been published only two

observations on the law of sickness, one from returns collected by the "Highland Society of Scotland," the other from returns recently collected and just published by the "Society for the Diffusion of Useful Knowledge." In the former, 85,000 years of life, in the latter, 24,000 years of life have been observed. The period of life observed, extended from the age of 20 to the age of 80 years; but for ages above 60, the results are not deserving of much confidence. In both observations, the quantity of sickness suffered by a given number living, increases with the age according to the same rate. *This rate of increase is identical with the rate of increase in the mortality according to age; and is expressible by the number or "constant" which I have used in the construction of all my theoretical tables of mortality, between the ages of 15 and 55 years.*

According to this new theory, the mortality at any year of age, exceeds that of the preceding year by 52.991 per cent, which is the same as saying that the mortality during each decennial interval of age, exceeds that of the preceding decennial interval by one-third, or 33.3 per cent, so that the mortality doubles in 23½ years.

I now subjoin a table of the relative and absolute sickness at each age, as experienced in the Scottish and English benefit societies, together with the relative results according to theory. The absolute numbers for England have been extracted from an article in the *British Medical Almanac* for 1836, from the pen of the editor of that valuable work. The relative may be converted into the absolute numbers by using the common multipliers appended.

	Relative Sickness and Death.					Absolute number constantly Sick, & dying annually, out of 100 living.			
Between Ages	20-30	30-40	40-50	50-60	Common Multiplier	20-30	30-40	40-50	50-60
Sickness { Scotland	.57	.67	1.00	1.83	1.97	1.13	1.32	1.97	3.60
England	.60	.71	1.00	1.69	2.56	1.54	1.83	2.56	4.32
Deaths . . . England	.51	.78	1.00	1.61	1.85	.95	1.45	1.85	2.98
Theory55	.74	1.00	1.43	—	—	—	—	—

On inspection of the above table of relative sickness and death, it will be perceived that for the three decennial intervals of age from 20 to 50, the coincidence between the theory and the observed facts is nearly perfect. Between the ages of 50 and 60 years there is an apparent, but no real opposition. For according to the theory of mortality, a new rate of increase begins, or a new constant comes into operation at some variable age between 50 and 60 years. The above theoretical numbers are founded upon the assumption that the new constant comes into operation at the age of 55 complete years. If an earlier age (say 53) had been adopted, the theoretical numbers would have agreed with the facts for England. In the case of Scotland, we have no information respecting the contemporaneous rate of mortality. In England, the elevated ratio of sickness between 50 and 60 years, coincides with the elevated ratio of mortality at the same age. The establishment of this coincidence between the law of sickness and the law of mortality is the main object of the present remarks.

The fact being acknowledged, that the sickness suffered by a given number living, increases with the age, according to the same law which regulates the increase of mortality, it necessarily follows—that there

exists a fixed proportion at every age between the quantity of sickness and the number of deaths. If there are two years of sickness to every death at any one age, the same proportion holds good for every age; at least between the observed limits of 20 and 60 years. According to the observation just made on English benefit societies, the constant proportion is that of one year and a half of sickness to each death at every age. From my own experience, I am inclined to the opinion, that two years of sickness to each death, is the proportion most generally prevalent. In the present inquiry, the exact amount of this proportion is a question of no importance; it is sufficient to know, that all observations (including a third unpublished extensive observation of mine) agree in showing this proportion to be constant at all ages.

Adopting as true the simple proportion of two years of sickness to each death, we obtain the following interesting consequences. If out of 100 living at any age, 4 are constantly sick, then it may be assumed as a fact, that the annual deaths will be two in number; and reversely. If at any age, the proportion of sickness to each individual, amounts to the 20th part of a year, the mortality in one year will amount to one in fifty. If at any age, the mortality

in one year is represented by one per cent of the living, the sickness due to each individual will be *one week*, which is nearly two hundredth parts of a year. The reader may easily trace similar consequences from adopting any other constant proportion than that of one year to one hundred.

Four years ago, I published some tables of health insurance, founded upon the principles above explained. The observation of the "Highland Society" was at that time the only one extant, on which the graduation of sickness according to age could be founded. I considered that great confidence might be reposed on the correctness of the relative results obtained from this observation, more especially as they were in harmony with the theory of mortality. But I entertained strong suspicions as to the correctness of the absolute results; and I felt persuaded, that the absolute sickness therein expressed, was very much less than that generally prevalent in England. In my published health tables, the scale of relation is that exhibited by the English and Scottish observations, or rather is that of the theory with which they so nearly coincide. But I have adopted for the base of my tables, a number which is more than 50 per cent greater than that of the table of the "Highland Society," and 20 per cent greater than that indicated by the English observation just published. The additional experience which I have since acquired, has served to confirm the opinion which I first hazarded respecting the absolute sickness most generally suffered by the English population. The results of my theoretical tables do not substantially differ from the results of Dr. Price's tables of sickness, which have been in universal use for fifty years. But every two successive numbers in my tables, bear the exact same relation to each other, which is not the case in Dr. Price's tables.

All my tables of life and health insurance

may easily be distinguished from the tables of any other person by the "constant" connecting together any two successive numbers. For example, at page 28 of my "LIFE TABLES," I have given the values at every age, of a life insurance of £100 for one year, deduced from the table of "Village Mortality," which is a theoretical table founded on Dr. Heysham's observation at Carlisle. At the ages of 20 and 21, the values are .6529 and .6724 respectively; at the ages of 30 and 31, the values are .8757, and .9018 respectively. The reader will easily perceive that the excess in each case is measured by the constant 2.99 per cent. Under the age of 55, for every ten years increase of age, the "Premiums for one year" increase *one third* part, very nearly.*

ON THE MORTALITY AT EACH AGE OUT OF A GIVEN NUMBER OF CASES OF SICKNESS.

Within the last few days, I have met with an extensive observation lately published by Dr. Southwood Smith, Physician to the *London Fever Hospital*, which brings the new theory of mortality, and the chief of its three constants, in close apposition with therapeutics and the practice of medicine. By means of this theory, when the number dying out of a given number living is known

* The reader may learn with some surprise that this new theory of mortality has been already extensively applied to practice, and has served as the basis of pecuniary engagements of great magnitude. For more than six years this theory has been the regulator of all the published lists of prices offered by a London Life Insurance Company, as may be seen by the annexed comparative table. The numbers in the first and second columns are in the exact proportion of 6 to 5 to the original numbers in the third and fourth columns:—

Age.	Annual Premium for Insurance of 100 <i>l</i> . according to			
	The Advertisements in 1830, and the Prospectus in 1836, of the same Life Office.		My Theoretical Table B 24, published in 1832.	
	For One Year.	For Life.	For One Year.	For Life.
20	£ s. d. 0 15 8	£ s. d. 1 11 9	.6529	1.3222
30	1 1 0	2 2 0	.8757	1.7493
40	1 8 2	2 17 1	1.1741	2.3776
50	1 17 9	4 2 0	1.5731	3.4159
60	3 5 4	6 10 9	2.7225	5.4459
70	6 18 4	10 18 6	5.7655	9.1041

at any one age, the mortality at every age of life is also known. By means of the same theory, as I have proved above, the relative quantity of sickness suffered at each age of life is also known. The constant of mortality is identical with the constant of sickness; the same number which measures the increase of mortality according to age, measures also the increase in the quantity of sickness suffered by a given number of individuals. The new observation proves that the same constant, in the case of fever, measures the increase of deaths according to age, out of a given number attacked. It appears in the highest degree improbable, that this number, of all others, should regulate the mortality in fevers, without being at the same time applicable to other extensive classes of disease. *The materials for the decision of this question abound or ought to abound in all public hospitals.

The observation of Dr. Smith is founded upon 6000 cases of fever occurring during the ten years ending in January, 1834. I subjoin the results in the form in which they have been published. I have added for comparison a column containing the numbers resulting from the theory, or from an increase of one third part (34.3 per cent) for every ten years increase of age.

Between Ages.	Out of 100 attacked by Fever, there die according to	
	Fact.	Theory.
5—16	8.3	—
15—26	11.5	12.5
25—36	17.1	16.8
35—46	22.0	22.6
45—56	30.5	30.3
55—66	40.7	40.7
Above 65	44.6	—

The coincidence between the facts and the theory is sufficiently close to prove all that is required. The small existing variations might have appeared, even if the coincidence had been perfect at intervals of five years of age. The theoretical numbers are founded on the assumption that the cases were equally distributed over each decennial interval of age, of which no evidence is presented. Dr. Smith has omitted to state the absolute numbers at each age on which his results are founded. The facts were probably very deficient in number at the beginning and at the end of his table; so that the results here are entitled to little confidence. The information would have been complete if he had given his materials distributed in quinquennial gradations of age. In the column of ages Dr. Smith has adopted an erroneous form of expression;

instead of "between the ages of 15 and 26," he evidently intended to say, between the ages of 15 and 25 complete years, which is the form generally adopted.

If it be admitted that the aggregate of severe diseases resemble fevers in their fatality according to age, we are led to the following novel but inevitable conclusions, applicable between the limits of 15 and 60 years of age. That a given number living at every year of age suffer the same number of attacks of sickness; and that the duration of each case of sickness at any age, is proportional to the mortality at that age. The deaths out of a given number living, vary with the age, in precisely the same degree as the deaths out of a given number attacked; consequently, the proportion between the number living and the number attacked is constant. The proportion of sickness (in duration) to the number of deaths has been proved to be constant at every age. And since the number of cases of sickness (out of a given number living) at each age is constant, the average duration of each case must be proportional to the number of deaths out of a given number living, that is, to the mortality. Assuming that one tenth part of the living at every age are yearly attacked by sickness, the facts above announced may be thus illustrated. If 1000 living at the age of 20 suffer 100 attacks of sickness, 10 deaths and 1000 weeks of sickness; then 1000 living at the age of 43, will suffer 100 attacks of sickness, 20 deaths, and 2000 weeks of sickness.

If it be confirmed by future observation, that diseases in general are subject to the same law as fevers, the knowledge of the new theory of mortality will form an indispensable branch of medical education. (This theory has been explained and applied in Nos. 605, 614, 640, 641, and 648 of THE LANCET.) Without this knowledge it will be impossible for a medical man to form any correct idea of the value of different remedies, when his patients differ in age. This theory will inform him that if he loses by death double the proportion of patients at the age of 43 than at the age of 20, the effect of his remedies in each case is the same.

46, Regent-square, London;
13th Feb., 1836.

HOPITAL DES ENFANS MALADES,
PARIS.

RESEARCHES INTO THE DISEASES
OF CHILDREN.

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND
PATHOLOGY.

TYPHUS FEVER IN THE YOUNG.

THE disease which French physicians are in the habit of describing under the various names of "typhus fever," "follicular enteritis," "dysenteritis," "intestinal exanthema," has hitherto been observed with care in the adult subject only. The facts on which the works of ANDRAL, LOUIS, CHOMEL, and others, on this affection, are founded, were exclusively collected in hospitals dedicated to the reception of adults. For many years, however, M. GUERSENT, during the course of his lectures, has been accustomed to point out the existence of this disease amongst children, and the researches which we have ourselves made, leave no doubt on our minds but that typhus fever occurs very frequently after the age of ten years. It may, we know, even occur so early as at four years of age, but we have never observed an example below the latter age, although we have examined more than 260 subjects, aged from twelve months to three years old.

The symptoms which characterize typhus fever in children, are nearly the same as those which are observed in adults. There are, however, in the former some peculiarities which depend on the age of the subject, and which we propose to illustrate in the following cases. We would also call attention to the points of resemblance which this disease is supposed to have with certain anomalous cases of hydrocephalus. For our own part, with all due respect to the opinion of some distinguished writers and practitioners, we must confess that we have never seen a case of typhus fever, however severe, which could be confounded with the symptoms of acute meningitis, or hydrocephalus. The distinctive characters of the two last-mentioned affections have always been so clearly marked as not to give rise to the least embarrassment or hesitation in the mind of the physician. Once indeed (and we shall report the case at length) we

saw a boy labouring under inflammation of the brain, in its most acute form. The physician diagnosticated typhus fever, and the error was not discovered before two or three days had elapsed, but here Mons. G. was led astray by a false history of the case, which he did not examine or in any way regard. The slightest examination of the patient would have been sufficient to reveal the true nature of a disease which was so little obscure as to be diagnosticated by the nurse.

The treatment pursued by the physicians of the hospital *Des Enfants* varies. MESSIEURS GUERSENT and JADELOT still continue BROUSSAIS' method, and employ sanguineous emissions. M. BAUDROUQUE prefers the purgative method, by Seltzer water in particular. Blisters to the legs and thighs are very frequently had recourse to, and bark is occasionally given, either by the mouth or in lavement, in the adynamic form. In cases of ataxic fever, baths, with cold effusion on the head, are a favourite remedy in the hospital.

CASE 1.—Louis Haquelle, 9 years of age, of a lymphatic temperament, hair light-coloured, skin white, &c., generally enjoys good health. He has been in Paris only five months, and lives with his mother and brother in a small chamber, ill ventilated, and unwholesome. On the 1st of September, without any known cause, he experienced a sensation of uncomfortableness, with loss of appetite and headache. These symptoms persist during the four days that follow: however, the child continues to go to school, but on the 5th he is seized with continued fever, excessive headache, accompanied by ringing in the ears, complete anorexia. The child was now confined to bed, and placed upon diet. On the 6th an abundant epistaxis. On the 8th the patient was received into the hospital.

On the 9th we examined the boy for the first time, and observed the following circumstances:—Position of the child is relaxed, he lies on his back; great prostration of force; immobility of the countenance; face pale; answers slowly, but correctly, if the attention of the patient be fixed by any particular question; frontal headache; ringing in the ears very troublesome; the lips are dry, and covered with a crust; the tongue red, smooth, and dry; thirst very great; no vomiting or nausea; the abdomen is sonorous on percussion, and tender when pressed upon, especially about the umbilical region; no stools since his reception into the hospital. We do not observe any rose-spots; skin warm and dry; pulse 108; inspirations 36; cough pretty frequent; the sonority of

the chest is normal. We hear a mucous rale on both sides.—*Acidulated water (syrup-mol) 2 jugs; 8 leeches round the umbilicus; emollient cataplasm to the leech-bites; lavement; diet.*

In the evening, exacerbation of the febrile movement; delirium, which continues during the night.

10. The agitation of the night previous has been followed by a deep prostration; somnolence; stupor; eyelids closed; the force and frequency of the pulse have fallen; pulse 96. The leeches have drawn a great quantity of blood; no active treatment is employed.

11. The evening and night have been found in a still higher degree of agitation; the patient left his bed several times, and it was necessary to employ the strait-waistcoat; in the morning, alternations of agitation and prostration; the child cries whenever the hand is applied to the abdomen, or any other point of the skin; two stools, one very liquid; we now perceive some lenticular rose-spots on the abdomen; the cough persists; pulse 112; respiration 36. *Remedies the same as before, except leeches.*

12. No remarkable change worthy of notice.

13. During the night a very abundant epistaxis, followed by excessive prostration. On the 14th, we find the patient still delirious at the morning visit; he is excessively agitated, and cries out constantly; it is with difficulty that we can count the pulse, which is 132; venesection was immediately practised at the arm, and about five ounces of blood taken away; the clot is soft; no trace of inflammatory crust.

15 and 16. The ataxo-adyamic symptoms are more prominent; the patient does not answer a single question, and is unable to recognise his mother. The lips are cracked, and furnish a sanguineous exudation; the tongue is dry, like a bit of parchment; pulse excessively feeble, varies from 112 to 120; temperature of the skin not much elevated; one liquid stool a day; the abdomen is tympanitic. *Tepid bath, with cold affusion on the head; four ounces of an emollient draught; sinapisms to the legs.*

17 and 18. The same remedies are continued. The patient is pretty calm; he answers some few questions, and does not seem to suffer any pain. Still the tongue continues dry and dirty, and the pulse frequent; the child has no diarrhoea.

20. The patient lies nearly in a state of coma; the eye is fixed and dull; the eyelids half open; the pupils dilated, but contractile; he does not answer when spoken to; emission of urine involuntary. The tongue and teeth covered with a dark crust; deglutition difficult; sensibility of the skin is now obtuse; pulse 118, small, irregular. *A blister to each leg.*

21. The stupor persists; the pupils are

now nearly immoveable. *A lavement of bark is ordered; two blisters to the legs.*

22. Tumefaction of the left parotid; somnolence as before; prostration the same; excretion involuntary. *Poultice to the tumour.*

24. The face of a yellow leaden colour; complete loss of consciousness; the patient utters a few feeble cries when he is changed in bed; excoriations on both thighs, on the sacrum, and over the right elbow; the arms are raised up from time to time; the extremities are cold; pulse weak and very compressible, 112. *Ether Draught; Lavement of Bark.*

From the 28th of September to the 2nd of October (the day of the patient's death), gangrenous eschars were formed on both thighs, and on the elbow, as also at the points to which the blisters had been applied. The leech-bites have become the seat of deep ulceration. The tumefaction of the left parotid has subsided, but a purulent fluid is discharged from the ears; the pulse remains feeble and compressible; the skin almost cold. The patient remains in a state of absolute silence, though on the 29th he seemed to recognise his mother. The diarrhoea is abundant, and the stools involuntary.

The wounds are dressed with a pomade containing bark; the ether draught is continued; a lavement of quinine given, and a few spoonfuls of claret wine by the mouth.

The patient died on the 2nd of October, in the most extreme degree of marasmus &c.

Examination of the Body Eighteen Hours after Death.

The body is extremely emaciated; large superficial ulcerations occupy the right elbow and both thighs. There are a few large sudamina on the anterior surface of the chest; cadaveric rigidity very well marked.

Skull.—Dura mater normal. The occipital fossa contains about two spoonfuls of fluid and clear serum. The arachnoid every where presents its normal colour, and is easily separated from the subjacent parts. The pia mater offers no other change than a slight serous infiltration; the substance of the cerebral hemisphere is moderately injected; when divided into three slices, we find no trace of ramollissement or other morbid change. The central parts offer their normal colour and consistency. The cerebellum is more pale and more firm than the cerebrum. The pons varoli normal.

Chest.—The larynx, trachea, and bronchi, are pale, and lined with mucus; the bronchial glands normal; the two lungs are pale anteriorly. The base of the right lung is united to the diaphragm by a pseudo-membranous exudation; in the upper part of the lung we find a portion, about the size of an ap-

ple, which has passed to a state of gray hepatization; the two other lobes are healthy; they contain but little blood; the left superior lobe is partially white, the inferior lobe normal. The heart is pale and flaccid, of a natural volume; pericardium healthy. The lining membrane of the lungs does not present any change of colour.

Abdomen.—The anterior wall of the stomach (internally) offers a patchy injection; the remainder of the mucous membrane is pale, and of normal consistency; the duodenum is tinged with bile; the jejunum and two upper thirds of the ileum are pale; in the inferior third of the latter intestine we observe no less than twenty-seven ulcerations, occupying indistinctively the glandulæ agminatæ and segregatæ; these ulcerations are superficial and merely involve the mucous tissue, which is soft and injected for the extent of about twelve inches near the cæcum; the ileo-cæcal valve is riddled with ulcerations; the mucous lining of the cæcum presents a livid colour, and is remarkably thickened; the glandulæ segregatæ of the colon are very apparent, and marked in the centre by a dark point; in the intervals the mucous membrane is pale and of good consistency; the mesenteric ganglia are not more developed than in the normal state; two or three are of a livid colour, and rather hardened than softened; the spleen, which offers its ordinary volume, is a little less firm than natural.

CASE 2.—François Chevalier, 4 years of age, was carried to the hospital Des Enfants Malades, on the 5th of November: he persons by whom he was conducted inform us that the child, who was convalescent from the whooping-cough only a few days, while on the route from St. Omer to Paris, was seized with vomiting, diarrhœa, and fever; these two latter symptoms persisted for five days following the attack, and on the evening of the fifth day were accompanied by prostration and some convulsive movements.

7th. Position variable; alternations of prostration and of agitation; stupor; low rires now and then; the child does not answer; the eyelids are half open, and the pupils are normally dilated; the sensibility of the skin is not changed; the lips are dry and cracked; the tongue dry and red; the thirst excessive; the abdomen tender and tympanic, painful every where on pressure; we do not observe any of the leucular rose-pots; stools frequent and involuntary; skin warm and dry; pulse very quick, about 40; cough rare, accompanied with a râle bilant at both sides of the chest. *Gum brought; sinapiens to the legs; diet.*

The same symptoms persist during the days of the 7th and 8th; we cannot observe any convulsive movement, or change in the

cutaneous sensibility; the child does not recognise his parents who come to see him, and continues to utter low cries from time to time; the sense of hearing is obtuse, and that of sight seems perverted. The evacuations are still frequent and involuntary. The pulse varies between 136 and 140. On the night of the 8th the child fell from his bed in an access of delirium; in the morning we find the right cheek blue and excessively tumefied; the lips and gums furnish a sanguineous exudation; the tongue is very foul and dark; the pulse is even quicker than yesterday; we count 160 pulsations; the tympanitis and diarrhœa persist. The little patient sank in the evening of the 9th in a state of stupor.

Post-mortem Examination.

Skull.—The vessels which run along the surface of the brain are evidently injected. The arachnoid membrane retains its normal transparency, and is easily detached from the convolutions, the sub-arachnoid cellular tissue is very slightly infiltrated with serum; the pia mater does not contain any granulations or purulent secretion. Three ounces of serum at the base of the skull; one ounce in the ventricles; the cerebral substance itself is quite free from injection. No trace of tubercles or ramollissement.

Neck and Chest.—Larynx and trachea normal. The bronchial tubes are gorged with mucus. The right lung adheres to the parietes of the chest for an extent of about two square inches. We observe a few gray demi-transparent granulations underneath the pleura covering the lungs. Both these latter organs are congested in the posterior part: the bronchial glands contain tubercular matter.

Abdomen.—The mesenteric glands are a little augmented in volume, of a rosy colour. The spleen is enlarged, but its consistence is normal. Liver healthy. The interior of the stomach is marked by numerous folds, whose edges are red. The mucous membrane, however, is free from softening; the membrane lining the interior of the duodenum is remarkably pale; the same decoloration exists in the jejunum and in two-thirds of the ileum; the glandulæ segregatæ are here very much developed. In the inferior third of the ileum, we count about twenty groups of an oval form, injected and prominent; three, placed near the ileo-cæcal valve, are ulcerated partially. The membrane lining the great intestines is furnished with a great number of follicles not ulcerated, but presenting a moderate degree of injection and slight diminution of consistence.

We will add some other cases, and attach to them some remarks in our next number.

CASE OF

ANEURYSMAL TUMOUR IN THE ORBIT

SUPERVENING INJURY OF THE HEAD, AND TREATED BY

LIGATURE OF THE COMMON CAROTID.

To the Editor of THE LANCET.

SIR,—I should feel obliged by the insertion of the following case in your publication. If not too long, I think you will consider it sufficiently interesting. Having omitted all details of treatment, which was that usually pursued in similar cases, and having confined myself to an account of the principal occurrences, I am not aware that the history could be advantageously curtailed. I have the honour to be, Sir, your obedient servant,

GEORGE BUSK,

Surgeon to the Seaman's Hospital.

H.M.S. Dreadnought, Feb. 19, 1836.

Richard Simmons, aged 20, a seaman, was admitted, July 13, 1835, labouring under the usual symptoms of concussion of the brain, with very considerable hemorrhage from the right ear, and a small wound behind the left. It was stated that he had received a very severe blow on the right side of the head, from the gaff of the vessel to which he belonged, by which he was rendered immediately insensible, and he was nearly so on admission, and could with difficulty be roused. At first he was very pale and cold, but in an hour or two he rallied. The hemorrhage from the right ear continued all night. On the following day he was quite sensible, but appeared dull, not complaining of any pain; pupils natural. On the 15th he was still dull, and completely deaf in the right ear. The eyelids, and the integuments around the left orbit, were swollen, apparently from serous effusion; they were not discoloured or painful. The pupil of the left eye was dilated and fixed, vision however was unimpaired, but he was unable to move the globe of the eye in any direction, and had slight paralysis of the facial muscles on the left side.

On the 18th some increase of inflammatory symptoms required attention, but was readily subdued. The pupil was observed to have become irregular, the irregularity consisting in an elongation downwards, and vision was not quite clear; there was occasionally a very partial rotatory motion of the globe, as if caused by the apparently involuntary motion of the superior oblique muscle. He had some headache, confined principally to the left side.

On the 21st his mouth became slightly

affected by mercury. On the 24th the headache was very trifling, but the left side of the face had become numb, and felt very uncomfortable. He complained of great dryness in the mouth, although his tongue was quite moist; there was also considerable purulent discharge from the right ear.

On the 25th the integuments of the left side of the face and head, extending to the vertex, were extremely tender to the touch, but without any morbid appearance. The pupils continued unaltered on the 28th, the conjunctiva of the left eye was much inflamed, and swollen from oedematous effusion, and on the 31st purulent matter was deposited between the lamellae of the cornea, at the lower part, with nebular opacity, but the eye was much less painful, and the headache gone; his health was now in most respects restored, and the functions were properly performed.

He began soon to complain of curious noises in the right ear, from which the discharge continued, and he was very deaf. The eye was not painful but the onyx was increased. In the beginning of September the paralysis and loss of sensibility were complete. The anterior lamellae of the cornea had given way, and a deep ulcer occupied the site of the abscess, of a healthy character. No change of importance took place until about the 29th of November, when he became affected with small pox, and was sent to the Small-Pox Hospital, whence he returned on the

1st of December. On his re-admission the state of the face unaltered; the eye generally was prominent and much inflamed, the ulcer on the cornea was large and in a very irritable state. The severity of these symptoms was soon pretty well subdued, and attempts were made by counter-irritation in every form, and other means, to remove the palsy of the face, without effect. Sensibility in some measure returned, preceded by anomalous painful feelings in the affected integuments. He continued in this state without any change in symptoms or appearance, except that the eye seemed to protrude rather more from the orbit than had been previously observed. The ulcer on the cornea filled up.

His general health being quite restored, and medical treatment not appearing to have any effect on the local complaint, he was desired and recommended to go to his friends in the country and trust to the efforts of nature. However, on the 1st of February, on making examination of the eye, I felt on pressing the globe a distinct pulsation, and, farther, found, deeply situated in the upper and inner part of the orbit, a firm pulsating tumour, which appeared about half an inch in its transverse and longest diameter; it was situated between the levator of the eyelid and the bone, and did not show itself externally, but when the

eyelid was raised, it caused some projection of the loose conjunctiva.

The pulsation of the tumour was accompanied by a very distinct whizzing sound, which could also be felt on pressing the parts in its immediate neighbourhood. Through the stethoscope a very loud aneurysmal whizzing sound was communicated, which could also be heard in applying the instrument over the inner canthus of the other eye, and on the left side of the frontal bone as high as the roots of the hair, and nearly as far back as the ear. He has very loud noises in the head in the right ear, resembling the sound of church bells, and in the left like the breaking of waves on the sea shore. He complains more of these incessant noises than of anything else.

Operation.—As pressure on the left common carotid put a stop to the pulsation and sound of the aneurysm, and to the noises in the head, it appeared to me that the placing of a ligature on that vessel presented ground for hope, and perhaps the only hope, of affording him relief or even permanent cure. As a preparatory step, he being very well able to afford the loss, twenty ounces of blood were taken in the evening, and, on the next day, February 2nd, the left common carotid was tied. Immediately on tightening the ligature, the pulsation and sound of aneurysm ceased, as also did the internal noises.

In the evening, four hours after the operation, obscure pulsation could be felt in the tumour, which, however, was not so large. The whizzing sound could also be plainly heard with the stethoscope, and over as large an extent. There was no pulsation in the temporal artery. The internal noises were at intervals nearly as loud as before the artery was tied, and at others nearly absent. He felt great pain on swallowing; pulse 110. He took ʒss of *Liquor. Opii Sedativ.*, and a wetted cloth was applied to the forehead and eye.

Feb. 3. In the morning, the pulsation was very obscure, and the sounds much diminished. The internal noises were also much less. He had had no sleep, and complained much of pain on deglutition, and on coughing, and of severe pain in the left hypochondrium. He has also a very troublesome cough, which he has had for some time. Pulse 120, sharp. He was bled to 16 oz. with immediate relief, and in the evening was much easier in all respects.

4. No remains of the tumour could be felt, and all pulsation was gone from the orbit, nor could any sound be heard with the stethoscope. The internal noises are quite absent, and his hearing is somewhat improved. Pulse 100, soft, skin moist, and tongue clean. The pain had left the left hypochondrium, but he felt some in the right when coughing. The wound was dressed, and the sutures were removed; union

had taken place to a great extent. In the evening the cough was occasionally severe, with mucous expectoration, and pain referred to the diaphragm. Pulse 120, soft, skin moist; bowels not opened. He had some calomel and compound extract of colocynth, and a mixture with sulphate of magnesia, and tincture of digitalis, and a linctus for the cough.

5. He felt very comfortable; has had several stools; countenance pale; pulse 100; eye less prominent.

6. Feels weak, but is quite free from pain; cough nearly gone. The conjunctiva is much less vascular than before the operation, and the cornea is clearer. Some grumous blood was discharged from the left nostril during the night. Pulse 90.

7. Pulse 80. The lips of the wound are opened, but it is filled with healthy granulations; sleeps well; appetite too good.

11. He sat up several hours, and on the 15th, the ligature came away.

18. The wound is all but cicatrized; he is quite free from pain or uneasiness; feels only hungry and weak; he is not yet allowed meat; pulse 70, soft. No remains of the aneurysm can be detected; the eye is returned wholly to its natural level; the upper half of the cornea is quite clear, the lower is occupied by a dense leucoma, to the centre of which runs a large red vessel from the conjunctiva. That membrane is hardly vascular, and vision is good through the clear part of the cornea when the lid is elevated; the pupil natural. The left side of the face is paralyzed, but sensibility is perfect except on the left side of the nose, where he feels pricking pains when touched. He has no power of motion whatever over the globe of the eye, and is still very deaf, and more so in the left ear than in the right, but has no noise in the head. His intellects have never been affected. Pulsation is very distinct behind the lower portion of the sternocleido-mastoid muscle, probably in the subclavian.

If any change of consequence takes place, while the man is under my care, I will take the liberty of communicating the particulars through the medium of this journal.

CASE OF

HEMORRHAGE FROM THE MOUTH.

By JULIUS WOLFF, M.D., Liverpool.

A. D., the commander of a vessel, twenty-five years of age, of robust constitution, being in good health, was attacked with a slight hemorrhage issuing from the mouth. In the beginning the saliva was only tinged with blood, but, soon afterwards, pure blood ran out uninterruptedly. Common remedies

were applied, without success. He then sent for his physician, who ordered astringent gargles, but ineffectually. Two days afterwards another physician was consulted, who ordered venesection, astringents to be swallowed, gargles, and warm foot-baths. Now and then the hemorrhage stopped for a few hours, but returned again, and so the patient went on for a fortnight.

January the 20th, 1835, at nine o'clock in the evening, I was sent for. I found the patient sitting in bed, his face flushed, and the pulse full, but not very frequent. The blood ran uninterruptedly out of his mouth, and I could not discover the source. The patient did not complain of any uneasiness besides, but was much alarmed at the great and constant loss of blood, and durst not move. I could not trace the hemorrhage to any cause. The patient was of a plethoric habit, and had frequently had bleeding at the nose, which was always difficult to be checked. I ordered a venesection, and a warm foot-bath, and during the bleeding the hemorrhage ceased, the astringent remedies being continued. About an hour afterwards it began again.

I now saw distinctly that the blood came from the roof of the mouth, and from a small spot of the gingiva, near the third lower molar tooth. I proposed to touch the part with nitrate of silver, and to extract the third molar tooth. The former proposal my colleagues accepted, but the latter they objected to. After the application of the nitrate of silver, the bleeding stopped, but a quarter of an hour afterwards it began again. The patient's face was pale, and the pulse small. Other complaints, which generally attend such great losses of blood, were not present.

I was now determined to extract the tooth; but on account of the blood which gathered so rapidly, I could not see the lower set of teeth. I caught a tooth in the region where I suspected the blood to come from, and after I had extracted it, the bleeding stopped. I filled the socket with wax, applied mustard plasters to the soles of the feet, and the before-mentioned medicine was continued.

The patient slept for a few hours, and recovered a little. Eleven hours afterwards the hemorrhage began again. My colleagues had by this time forsaken me, and the case being now left to my sole care, I had him placed in an arm-chair, and applied uninterruptedly every two minutes fresh ice to his cheeks, and let ice melt in his mouth, and soon afterwards the bleeding was checked. The room was kept as cool as possible, and the half-sitting position in the arm-chair and the application of ice were continued. From time to time the warm foot-bath was used. He was put on low diet, and I gave him decoct. crystal. tartar. c. syrup. rib., for a drink. The hemorrhage

stopped for thirty-six hours, and then began again with renewed violence. During this time the patient had recovered a little, but began now to complain of giddiness, noise in the ears, and dimness of vision. The pulse was trembling, and the countenance anxious. The last-mentioned remedies were continued. I filled the whole cavity of the mouth with wax in such a manner that the air could only go through the nose, and by means of a bandage which I applied, not the least motion of the jaw was allowed. The nourishment of the patient was beef-tea, with eggs, which was poured with teaspoons between the lips, and was swallowed very well.

After ceasing for ninety hours, during which time the patient recovered a little, the bleeding began again very severely. I now had recourse to the actual cautery, touching the socket of the tooth, and the whole roof of the mouth, until the bleeding stopped. In twelve hours it began again, but the cautery being repeated thirteen times, it was finally checked. The scab caused by the iron came off after the roof had obtained a new integument.

Mr. D. bore all this with admirable patience, though the frequent return of the hemorrhage dejected him sometimes. It had lasted now, with the interruptions stated, for more than five weeks, the shortest intervals occurring in the first fortnight. The patient was kept during more than six weeks in the half-sitting position in an arm-chair in a cold room, where uninterruptedly the application of the ice and the astringent medicine were continued.

After these six weeks, I allowed him to sleep in his bed again, but in a very cold room, I gave him *acid. sulphur. dilut.*, and, afterwards, *serum lactis alumin.* (consisting of *lactis vaccini*, libram unam, ebulliat in vaso figulino; dein adde *aluminis* drachmam unam; colatura D. S., for a drink); ordered proper diet and rest; afterwards, proper exercise in the open air, and on the eighth week of my treatment Mr. D. visited his friends again, after having been reported frequently to be dead. A few months after he recovered the red bloom of his face.

In such a case I should like to consult a Hahnemanist. What an effect would the 24th dilution of a grain of aconit. napel have produced here? or the quintillionth or the decentillionth part of a grain of *nux vomica*, *arnica montana*, *ignatia*, *belladonna*, *chamomilla*, *cafeia arabica*? The diet alone, I think, would have been ~~hahnemanically~~ of the same use as the doses of *cafeia arab.* For in the choice of the diet I was very particular. He took at first water-gruel, peeled barley, cooling drinks, and afterwards beef-tea, with an egg, which, I suppose, could, hahnemanically also, not increase the hemorrhage.

I do not think it improper to add to this

subject the following remarks:—The mother of Mr. D., 62 years of age, of robust constitution, experienced the cessation of menses 6 years ago, but was until that period always regular, and not copious. When young she frequently suffered from hemorrhage of the nose. In the month of February she suffered from a very severe inflammation in her throat. I ordered leeches, but the surgeon refused to apply them. (There is in Germany a lower class of surgeons, who apply leeches, bleed, etc.) When I asked him the reason, he told me that he was "afraid that he might not be able to check the bleeding, because he knew from experience that it was not an easy matter to check a bleeding in this lady. But he did not object to a venesection. He opened a vein, and I applied two leeches on the sternum, in order to convince myself of what the surgeon had stated. The wound of the vein bled for many hours after a bandage was applied, and I was obliged to make a strong compression before the desired effect could be produced. To the leech-bites constant compression, and many other remedies, were applied, yet eight days afterwards a little blood was now and then yielded.

Mr. D.'s sister, about 30 years of age, tall and stout, had had three children, and suffered, when young, frequently from bleeding at the nose. Her menses were regular, and not copious. When brought to bed, her loss of blood was not uncommonly great. She assured me, that a few years ago she cut her finger, and lost such a quantity of blood, that she fainted several times, and the hemorrhage was stopped only with very great difficulty.

Mr. D.'s younger brother, who frequently suffers from hemorrhages of the nose, had a molar tooth extracted. The bleeding was not stopped until the third day arrived, and repeated application of the actual cautery had been made.

Neither Mr. D.'s father, nor his elder brother, was liable to hemorrhages, but this tendency existed in the family of his mother, several of them having suffered from it, one of them a few years ago really dying from hemorrhage. The disposition is therefore inherited from the mother.

94, Duke Street, Feb. 1st, 1836.

REMARKS ON MR. OSBORN'S ANALYSIS OF BLOOD.

To the Editor of THE LANCET.

SIR,—In THE LANCET for Feb. 20th there is a paper by Mr. Osborn, chemist, of Southampton, on "Petroleum in the Blood." The alleged detection somewhat surprised me, as petroleum really means a spirit or

oil of rock, and was so called because it was distilled from a mineral. Mr. Osborn, however, calls it a peculiar kind of petroleum, but fails, I think, to show that it in the least resembles petroleum in its character and properties. The first test which he made use of was that of touch, the second that of smell; the one was disagreeable, the other adhesive. If this be precision, then indeed chemistry is a superficial science. He next says, "it is soluble in alcohol, and turns of a thick brownish white colour, when well mixed with water. By evaporating the spirit, the tar again floats on the surface." Of what? He does not say, neither does he tell us, whether it is the alcoholic solution of the tar or the tar itself which turns of this strange colour. He says very little else about its chemical and physical properties, except that "it burns like common tar (not like petroleum), leaving a smell not unlike that of burnt feathers." The smell of burning animal matter is much alike in all cases. He then ("the quantity obtained being too small for redistillation") heats a little in a bulb glass, to the temperature of ebullition, when a spirit was given off, which took fire when brought in contact with a lighted taper." What the temperature of "ebullition" is he leaves us in the dark, and how he can call that a "spirit" which might have been a gas (for he never condensed it, even if it were the vapour of a spirit), I am at a loss to determine.

The process made use of is most incompatible with any correct mode of searching for a minute quantity of matter in any body, and at the same time shows a want of knowledge of chemical equivalents which is quite at variance with his title of "chemist." He begins, without any visible object in view, by adding "an ounce of concentrated sulphuric acid to each pound of blood (of which he takes eight pounds) before separation;" which he allows to stand four-and-twenty hours, being frequently stirred; to this he adds for each ounce of sulphuric acid, two ounces of carbonate of lime, but why he was so liberal of chalk does not appear, as equal weights, or at any rate a very slight quantity more in weight of chalk than of acid, would have formed a perfectly neutral salt, forty-nine parts by weight of oil of vitriol uniting with fifty of carbonate of lime, they being as nearly as possible equal weights.

Now as Mr. Osborn was working for proportions, as he afterwards states he was, he appears to me to have gone in a very clumsy way to attain his object: he makes use of "an earthenware retort" (capable, of course, of holding eight pounds of blood) having its beak lengthened with "a tin tube three feet long, the extremity of which was introduced into a quart bottle, the bulk of the retort into a sand-bath, which was placed in a charcoal furnace." When ana-

lyzing for proportions, it is customary to use apparatus of glass to prevent contamination or loss. That Mr. Osborn cannot have had sufficient practice to entitle him to make and publish an analysis of the blood, is, I think, from these statements, apparent; and as far as I am capable of judging, he appears to have obtained nothing but the well-known animal oil of Dippel, as the substance, so far as can be gathered from his description, appears to resemble it in its characters and properties.

I should not have intruded myself on the notice of your readers, but that I have observed lately a great number of persons, attempting an analysis of the blood, who have no pretensions to a scientific or practical knowledge of chemistry. Hoping that this analysis of Mr. Osborn's paper will obtain a place in your valuable and equitable journal, I remain, Sir, your obedient servant,

W. C.

Brompton Square;
February 22nd, 1836.

REMARKS

ON

DR. WILLIAMS'S RECLAMATION

RELATIVE TO DR. HOPE'S LATE EXPOSITION

OF THE

SOUNDS OF THE HEART.

To the Editor of THE LANCET.

SIR,—The perusal of some remarks by Dr. Williams on the newly-adopted opinions of Dr. Hope, in the *Medical Gazette* of September 12, 1835, to which my attention has just been directed, has induced me again to request of you the favour of a place in THE LANCET for a few observations on the heart's sounds.

In 1832 I forwarded to THE LANCET a paper containing an explanation of the heart's normal sounds, the correctness of which has been partially, and, I have little doubt, will, sooner or later, be generally adopted. Very similar views had, I have since found, a short time before been advanced by M. Rouanet, at Paris, in an inaugural thesis, and, previously to this, brought forward by Dr. Billing, when President of the *Hunterian Society*, in a paper read at the annual meeting of that Society in 1832.

These views were then new, and opposed to the opinions of all other writers on this subject. The views of M. Rouanet and myself with regard to the heart's second sound, have been quoted and adopted by Drs. Hope and Williams. The explanation of the first sound, however, as given by M. Rouanet, has been adopted by Dr. Hope

with an important modification, which modification Dr. Williams asserts, in the paper above mentioned, is nothing more than less than his own original explanation, first published in his *Lectures on diseases of the chest* in 1828, and to establish the point in favour of his former view, that the heart's sounds were muscular sounds, Dr. Williams makes, amongst others, the following remarks:—

"Dr. Hope, in his work published in 1832, ascribed both the first and the second sounds of the heart to the collision of the particles of fluid; and, until the publication of the 'Appendix' in April last, he had not, in his several writings on the subject, expressed any distrust or qualification of his original opinion."—(These views, he it remembered, were, at one time, adopted by Dr. Williams, but they met with a complete and unanswered refutation by me, in a paper in THE LANCET of Sept. 23rd, 1833.)—Dr. Williams continues,—"Here, however, he comes to the conclusion that the second sound is caused by the closure of the sigmoid valves, and that the first is compound, 'consisting, first, possibly, of a degree of valvular sound: secondly, of a loud smart sound, produced by the abstract act of sudden jerking extension of the muscular walls, in the same way that such a sound is produced by similar extension of the leaflets of a pair of bellows; to avoid circumscription, he calls this the sound of extension; thirdly, a prolongation, and, possibly, an augmentation of this sound, by the sonorous vibrations peculiar to muscular fibre.'"

The same experiments which led Dr. Hope to adopt and modify the opinion of M. Rouanet as above, led Dr. Williams to the following conclusions:—"That the first sound is not dependent on the closing of auriculo-ventricular valves is evident, from five observations in which the closure of these valves was partially or completely prevented, yet the first sound continued."

I have here to remark that the experiments referred to, as detailed by Dr. Williams, were not conclusive in favour of his view, but the contrary; for we have it on the authority of Dr. Hope, that the partial impediment to the action of the valves produced an equivalent alteration in the intensity and clearness of the heart's sounds.

These remarks are also at variance with the following, which occur in the next page:—

"If some of these circumstances be removed, as in my experiment, where the resistance of the valves, or the mass of blood, was taken away, the sound of the heart will be heard in the duller and more subdued character of common muscular sound. Probably, in common pulsations, the ventricles do not attain the degree of tension that is sonorous until the closing of the auricular valves; this closure, as the consequence of the resistance, brings about its sound."

ic muscular tension, which continues until the contents of the ventricles are sufficiently expelled. This accounts for the sudden snapping commencement of the first sound, and suggests how the due action of the valves contributes to its clearness. The auricular valves, the chordæ tendinæ, and the internal fibres of the ventricles, if they train the same degree of tension as the exterior of the ventricles, may have an equal share in the production of the first sound; but I am disposed to think that what we hear proceeds chiefly from the contracting business of the external walls of the heart, both because they are nearer to the ear, and because, in one observation, the contraction of the left ventricle upon my finger within was by no means so abrupt or strong as that of the exterior, as felt by the other hand, and still heard through the stethoscope."

I cannot conceive how Dr. Williams can question, whether or not the valves attain a degree of tension equal to that of the muscular substance of the ventricles. In a paper, in *THE LANCET* of Jan. 12, 1832, I have demonstrated that the valves must attain a *more abrupt* and a *greater tension* than the substance of the ventricles, and I feel confident that Dr. Williams's acquaintance with physics would, after a short consideration on the point, lead him to the same conclusion. Dr. Williams should remember, that his finger trammelled the action of the very valve whose degree of tension he assumes to have measured. The ingenious arguments, in the latter part of the above quotation, appear to me to involve a *petitio principii*; they certainly do, if Dr. Williams would wish to infer that the first sound is not of valvular origin, because the sound heard by the ear, is that occurring in the internal fibres of the ventricles; for, the question is not, *Where* are the vibrations? but, What is the *cause* of those vibrations?

Again: "The *cause* of sound is resisted and on; and the strongest and quickest motion, most abruptly and forcibly resisted, will give the loudest sound. Hence the ventricles, rapidly contracting from their flaccid state, give most sound when their motion is *first resisted* by the mass and weight of the blood within them, which is confined within the auricular valves."

And when, I would ask, is the motion "first resisted?" Why, when the valves close. And when is the blood "first confined?" Why, when the valves close. *Ergo*, Dr. Williams concludes that his explanation, given in 1832, of the first sound is a muscular sound, is correct. Really, this appears to me to be a decided *non sequitur*. Dr. Williams further argues, that the above three explanations of Dr. Hope are all contained in "one simple principle,"—that of sudden tension. This, I think, is perfectly correct; but I cannot allow that this principle is

contained in any of Dr. Williams's previous expositions of the heart's sounds, nor that the above explanations are applicable to muscular sound; but I think the reader will perceive that all the above explanations are resolvable into that given by me in *THE LANCET* of Sept. 23, 1833, in a paper to which Drs. Williams and Hope have referred, and from which the following quotation is taken:—

"Any flexible solid, suddenly brought from a state of relaxation to a state of tension, vibrates, and its vibrations are sonorous or not—i. e. audible or not, according to its physical structure. At the commencement of the systole of the ventricles, their auricular valves are flapped into play, and, at the instant of their closure, the whole substance of the ventricles and the valves are suddenly brought to a state of tension, and then, consequently, they vibrate. I leave it to the reader to determine whether the vibrations of the valves, or of the muscular substance of the ventricles, would most contribute to the formation of the first sound."

The objections advanced by Drs. Hope, Williams, Boulland, and other writers, may be valid, and may apply to the theory of M. Rouanet, but they do not apply to mine. I remain, Sir, your obedient servant,

F. L. BRYAN.

Stowmarket, Feb. 23, 1836.

GERMAN JOURNALS.

Press of matter prevents us from passing in review all the articles contained in the last numbers of the German journals which we have received; we shall, therefore, content ourselves with an enumeration of their contents, and a brief notice of the most important papers to be found amongst them.

Hecker's Annalen, Vol. II. Nos. 3 and 4; and Vol. III. No. 1.

1. On the Influence of Trades and Professions on the Health and Mortality of a Population. Part I. By Dr. FUCHS. We shall wait until the second part is published before giving an account of this interesting memoir.

2. On Gastro-enteritis. By Dr. KOHLER of *La Charité*.

3. ON SCARLATINA.

By Professor LICHTENSTADT of Berlin, St. Petersburg.

This is a long memoir, containing an account of the epidemic scarlatina which prevailed in St. Petersburg in the winter 1834-35. The author, agreeing with most writers, considers scarlatina as a disease which

is eminently contagious; he cites several cases, where it was transmitted from house to house through the medium of visitors, who themselves remained unaffected; however, by using proper precautions, he was always fortunate enough to avoid the danger. The period of contagion is often protracted to a very considerable length of time; the professor was accustomed to consider six weeks as the maximum, but during this epidemic the disease was evidently transmitted from one individual to another, at the distance of eight weeks from the commencement of the attack; a long-continued exfoliation of the epidermis seems to favour the prolongation of the contagious period. The only method of checking the disease, is to avoid as much as possible all circumstances by which its contagious property may be propagated. Dr. Lichtenstadt has experimented with belladonna—a remedy much praised latterly as a preventive, but without any good effect.

The march of scarlatina may be divided into three periods; that of invasion, that of eruption, and, finally, the period of desquamation. The first rarely lasts beyond twenty-four hours; as a general rule, it may be laid down that the disease is dangerous in proportion to the shortness of the first period; however, this admits of several exceptions.

The second period, or that of eruption, lasts usually from seven to nine days, unless it is cut short by the child's death. In the latter case it may terminate in eighteen hours (one example of which kind the author observed), or in thirty-six hours after the commencement of the period. The colour and extent of the eruption are very various. Some writers advance that a deep-red colour, uniformly spread over the whole body, is a favourable sign; on the contrary, the author thinks the danger is always increased in proportion to the intensity of the eruption.

The pulse, as is usual in this disease, was always quick, and not reduced by the appearance of the eruption; at 100, it was not an unfavourable symptom; the pulse often rose to 120, and this also without indicating any great danger; but the disease was always the more grave and fatal, in proportion as the pulse exceeded this latter degree of frequency.

Bloody evacuations were sometimes observed during the course of this period, but they did not seem to exercise any remarkable influence in its march or termination; several children were seized with epistaxis, some recovered; others died. One patient, who died on the fourth day after copious loss of blood from the nose, was seized thirty-six hours later with violent hemorrhage from the vagina. The indications drawn from an examination of the urine, or alimentary excretion, do not present anything remarkable. The state of the tongue has always been considered of great import-

ance, especially for the diagnosis of scarlatina. We have almost invariably observed the red, developed papillae, at a very early stage; however, the author says, in the present epidemic, for the first few days after the appearance of the eruption, the tongue was covered with a whitish, or a yellow-white fur, by no means characteristic of scarlatina, and not differing from that observed in common fevers; however, the anterior portion and edges of the tongue gradually assumed a reddish colour, which soon acquired the true scarlatina tint.

Some cases of gangrene of the fauces were observed, but the author saw hardly any example of the diphtheritic inflammation described by BRETONNEAU as extending to the pharynx and larynx. In one case this gangrenous inflammation was complicated with croup. In several cases also, especially towards the end of the epidemic, the author observed a ringing cough excessively like croup, but all these terminated favourably. The duration of the desquamating period is various. In some cases the desquamation was not completed six weeks after the commencement of the disease; in others it was still more protracted. The complication of this period was, as usual, anasarca; general anasarca and abdominal dropsy often occurred, but never in a fatal form: one case of fatal thoracic effusion presented itself in the case of a child four years old; the cavity of the chest contained two pounds of clear fluid. No case of acute effusion into the cavity of the skull was observed.

The treatment pursued by the author seems very rational, and does not differ in any remarkable manner from that which would be adopted in this country. He justly condemns the antiphlogistic method, when pushed to too great an extent, preferring mild cooling regimen, and a moderate use of blood-letting when absolutely necessary. The experiments which he made with cold affusion do not seem to have given very favourable results, and he prefers rubbing the skin with warm oil. The inflammation of the throat did not appear to be alleviated in the least degree by leeches, and purgatives with emetics had not a much better effect. In a word, the result of the author's observations on the treatment of the second period is, "that medicine is only of negative value, and that when a cure does take place, we are indebted to nature for the fortunate result."

THE MOTOR AND SENSITIVE NERVES.

4. De Differentia et Nexu inter Nervos Vitæ Animalis et Vitæ Organicæ. By J. VAN DEEN. Lugd. Batav. 1834.

THE fourth article has the above title. After a short description of the difference

and relations existing between the nerves of animal and organic life (the motor and sentient nerves), the author proceeds to distinguish these nerves according to the difference of their functions. The first chapter contains a rapid history of the experiments hitherto performed on the anterior and posterior branches of the spinal nerves, and a description of the manner in which the nerves are distributed in the posterior extremity of the frog. The first and most external of these nerves (*nervus inguinalis*) passes out between the 7th and 8th vertebra, and is distributed to the muscles and integument of the inguinal region and upper part of the thigh. The second branch (*nervus cruralis*) passes to the muscles and skin of the thigh. The third (*nervus ischiaticus*) is lost in the integuments and muscles of the leg and foot. These three nerves have each a double root, while the fourth, or pudic nerve, distributed to the skin of the perineum, has only a single posterior root. The latter is furnished with a whitish oblong ganglion situate outside the coccyx, while the ganglia of the sensitive roots of the other nerves are placed in the vertebral canal; these four nerves anastomose with each other and with the sympathetic nerve. The author repeated the usual experiments on the anterior and posterior roots of the nerves in frogs, and obtained results exactly similar to those described by Müller and Panizza. He next endeavours to ascertain the nature of the connection between the several nerves just described. After dividing both roots of the inguinal nerve, the frog was unable to draw up the foot towards the abdomen. Division of the crural nerve produced paralysis of the thigh and leg. Division of the three branches was followed by paralysis of the whole extremity; when the inguinal nerve was divided above its connection with the crurals, the motion of the foot towards the abdomen was equally destroyed. After division of the united branches of the inguinal and crural nerves, the animal could no longer move the thigh to the abdomen, and the same result was sometimes obtained by cutting through the inguinal nerve above its junction with the crural. The author explains this latter phenomenon by the fact that the inguinal nerve is often very large, and contains some of the primary filaments of the crural. When the superior part of the anastomosis between the inguinal nerve and the crural is cut through, the whole limb is paralyzed, just as if they were divided below the point of union; and hence the author concludes that the primary filaments of these nerves here not only lie in juxtaposition, but decussate each other. If the ischiatic nerve is divided above its junction with the crural, the toes, foot, and the greater part of the leg, are paralyzed, but the animal can still jump. On the con-

trary, when the crural is divided, this motion is lost, although the action of the foot and leg remains.

In order to verify the experiments of Flourens, both hemispheres were removed in a rabbit; the animal lay in a state of stupor, but when the extremities were stimulated it moved: three quarters of an hour later the cerebellum was removed, and on dividing the corpora quadrigemina, violent convulsions came on, and death followed in an hour. The removal of the right hemisphere in another rabbit, did not produce any external signs of pain, nor did the division of the olfactory or facial nerves of the same side give any sort of effect. The animal lay quiet, but moved when the extremities were pinched. Touching the corpora quadrigemina, caused rapid motion of the limbs. An hour after the experiment, the animal closed the eyelids when light was passed near the eyeballs; the pupil contracted; during the night it lay quiet, and died in thirty-one hours after the operation. A portion of the cerebellum was removed in another rabbit. The animal gave no signs of suffering: on cutting down deeper, some lateral motion was produced: after some time the motions ceased, but the animal was unable, with all his efforts, to raise himself up. Resection of an hemisphere in another rabbit, produced a rotatory motion that lasted six hours, and did not reappear, although the animal lived for seven days. From the above experiments the author concludes that the cerebrum is the organ of volition; the cerebellum that of co-ordinating motion; the spinal marrow the conductor; and the nerves the exciting agents of motion. In the second chapter, the author endeavours to show that the lower an animal is in the scale of creation, the less difference do we find between the nerves of animal and organic life. When a simple nervous system exists, it serves equally for motor and sensitive functions: he regards the recurrent nerve of insects as the *nervus vagus*, which possesses no evident sensation, according to his experiments; it has the peculiarities of an organic as well as an animal nerve. The independence of the *vagus* and sympathetic nerves is proportioned to the elevated scale which the animal holds (as Weber first proved), and this fact is confirmative of the opinion advanced by our author in the connection between the nerves of animal and organic life. As a proof of its truth, the author quotes a discovery which he made while observing the larvæ of the rana paradoxa. He found a lateral branch of the *nervus vagus* (similar to that in fishes) which anastomoses with the branches passing to the branchi, with one distributed to the head, and with one for the intestines.

The sympathetic nerve is altogether absent in the beginning, and only makes its

appearance in the course of the animal's development. The vagus at first grows in proportion to the growth of the tail and anterior extremities. When these are fully developed, and the animal assumes more the organization of a land animal, the vagus declines. The formation of the vagus and the sympathetic nerve are in inverse proportion, and the animal and vegetative nerves are the more independent of one another in proportion as the animal holds a higher rank in the scale of creation. The author distinguishes three classes of nerves, according to the independence or non-independence of the animal and vegetative nervous systems: viz.,—1st. In the lower classes of animals we find only one nervous system, both being united to form this one. 2nd. The distinction is imperfect in those cases where the vagus, detached from the central nervous system, possesses animal and organic functions. 3rd. Here there is a distinct sympathetic nerve, which is the more perfect and independent as the animal is placed higher amongst the mammalia.

The mutual connections between the organic and animal nervous systems has a double object. On the one hand it endows the organic nerve with motor and sometimes even with sensitive properties. On the other hand it gives organic force to the animal nerves, without, however, interfering with the sympathetic affections.

The sensorial nerves consist, 1st. In the chief nerves of the senses which have no connection with the other animal nerves, nor any direct or indirect anastomosis with the organic nerves. (The *nervus centralis* perforates the optic, and probably a similar state occurs in the so-called double anastomosis of the facial and auditory nerves.) 2nd. The nerves which convey not only the qualities of things, but also their effects on our bodies. These comprehend the nerves of taste and feeling; all these nerves, in addition to their peculiar function, are possessed of sensibility in general. 3rd. The remaining sensitive nerves, which seem simply to possess the power of sensitiveness.

The motor nerves are, first, nerves that do not anastomose with the sensitive nerves: to those belong the third, fourth, and sixth nerves; and, secondly, those that unite with sensitive nerves. The motor power of the organic nerves is derived from the motor cerebro-spinal nerves; every one knows that this property continues a long time after the central nervous mass has been removed. On the other hand, the animal nerves possess certain organic properties, viz. the nerves which accompany the arteries. Neither the brain, nor the spinal marrow, nor the sympathetic nerve, can with propriety be regarded as the centre of nervous actions. Were the latter the case, for example, for the celiac plexus, an

animal would die immediately when it is removed, and not gradually, from peritonitis, as the author has found. We can only discover a centre of this kind in inferior animals, where the animal and organic systems are united together, but in higher orders if we seek this, we must look for it in a point where the animal and organic powers are united, and from which they act upon the other nerves. This point is the medulla oblongata, which gives origin to the *pervus vagus*. This is possessed of a power intermediate between that of the animal and organic nerves. Its animal function cannot be destroyed (as in animal nerves) without injury to its organic functions; it is developed before the sympathetic. Respiration, the function over which it presides, is a mean between the animal and organic functions, and, besides this, it exercises an evident influence on the digestion and circulation, and is the first which enters into activity in the new-born child.

PAROCHIAL MEDICAL CONTRACTS.

"DA DENTRAM MISERO."

To the Editor of THE LANCET.

SIR,—In the concluding part of my last communication (which you did me the honour to insert in THE LANCET of the 2nd ultimo), some of the errors of the Poor Law Commissioners are briefly recorded. I pointed out the increase produced in the number of medical monopolies; the still further reduction of the late wretchedly low rate of medical pay; the inhumanity of farming out the care of sick paupers to the lowest bidders, by advertising for tenders, and the impropriety of employing young men, immediately from the schools of medicine, to attend in difficult and dangerous cases of midwifery &c. I observed also, that by paying the surgeon a fixed price per patient, while the power of granting orders for his aid was limited to the relieving-officer, severe and dangerous cases only would be committed to his charge, and often not until it would, under Divine Providence, be too late to save the lives of paupers. And, lastly, my tears were expressed as to what might become of those unhappy patients, for whose medical care nothing was to be paid. Certainly a most unaccountable method of providing medical aid for a portion of the sick, to leave the surgeon that he is not to receive any remuneration for his remedies and services. In the Commissioners' Report to Lord John Russell (Aug. 8, 1835) are the following words:—"In some Unions, as in the Wexcombe Union, it has been provided, that the terms of the contract should be a remuneration, at

a given sum per head, on the number who receive medical aid; but with the proviso, that the gross charge shall not exceed a given amount;" and again, "that the aggregate charges for medical relief within the new Unions, shall not exceed the aggregate of the former expenditure for medical relief in the separate parishes now included in the Unions." The old salary was fixed at 10*l.* per annum; the new charge is 2*s.* 6*d.* per patient; the number of patients 100; of which the first 80 are to be paid for (eighty half-crowns being equal to 10*l.*), and the last twenty are to be attended and provided with medicine gratis.

In this letter, Sir, allow me to comment on some other points, introduced in the above-named Report, concluding with remarks on the scheme proposed by your ingenious correspondent "RURICOLA," in the course of which his strictures on my plan, it is to be hoped, will be sufficiently answered.

The advantages of the Commissioners' system of medical contracts are singularly illustrated in their Report, by the evidence of a medical witness. "I approve of the system," says the witness; "but the amount in the present contract is inadequate. I think I shall lose a guinea a-week by it. In some of the parishes it is at present only one-third of what I have received in former years for the same time. But I approve of the system for these reasons; it is a self-acting check upon the relieving officer in giving improper orders, or withholding proper orders, upon application for medical relief, in making the patient feel that, in receiving it, he is a pauper, and causing the parish a specific charge for him; and upon the medical man, by causing an inquiry into each case, so that none can escape attention, and by that means also securing proper attendance to the patient." Certainly no relieving officer, in the *honest* discharge of his duties, will give improper orders in favour of medical men. But, according to the Report, "the inferior officers" (under the old system) "have been fed by the medical officers, to search out, and give them information of, cases, under the expressed, or the implied condition, that they should be allowed to charge whatever they pleased for attendance and treatment of non-parishioners, under suspended orders of removal, or orders of medical relief given by the overseer." Now, suppose the relieving-officer to be fed for granting as many orders, during a healthy year, as would not otherwise have cost the amount of the old salary; or suppose the surgeon to be his son, or his nephew, or his bosom friend, what becomes of "the check" on giving "improper orders?" On the other hand, imagine them at variance with each other, while the relieving officer is anxious only to prove his zeal for economy, and to curry

favour with most of the guardians; where is the check on "withholding proper orders?" And, lastly, how is "proper attendance to the patient secured," under a system which entails on surgeons a heavy pecuniary loss?

The Report speaks of the "credit of the appointments," "the wider fields they offer for the display of care and skill, leading to more profitable practice,—the inducements differing in degree, but being similar in kind, to those upon which men of the most eminent skill find it to their interest to give their services to the chief medical institutions of the country." *Credit* in receiving an appointment from guardians as the reward of a medical contract, entered into by letters of tender, through public advertisements, in precisely the same way as that in which bakers and butchers are appointed to serve the Unions with bread and meat!!! It is admitted, by implication, that these enviable fields for the display of practice (and horse-nauship) at half-a-crown, or three shillings, per patient per annum, are *unprofitable*; which circumstance, together with the degrading condition of the paltry pay annexed to those appointments, will sufficiently explain why many of the most respectable surgeons in the provinces are at issue with the Commissioners.

If medical men are to be paid so much per patient, I would humbly request the Commissioners' attention to the following rate of pay, founded on the scale already constructed by me, and the relative number of sick annually occurring among a given number of paupers.

Without quoting Dr. Rees, and other able writers, on this point, and without pointing out causes which must ever produce variations in calculations of the above kind, perhaps I may be permitted, at once, to set down the number of sick as one in every three persons throughout the year. More than this proportion occurs in the parochial medical practice of this town, and less in the adjoining rural parishes; but, as a general average, the proportion of sickness to health, occurring annually, is not over-rated, considering that paupers consist of persons of all ages, and of both sexes, and that they are exposed in a degree beyond all other classes of the poor, to the evils of poverty. My former scale of prices, per pauper, begins with 2*s.* for the care of from 50 to 300, and thence descends through fractions, as the scale ascends by single hundreds, to 10,000 persons; the price, per pauper, at that number, being 9*d.* and a fraction. For patients, therefore, I would suggest a scale, beginning with 6*s.* (per patient) for 100, and below that number descending in price, in like manner, as the scale ascends, by every 33 patients, up to any number attended by the medical officer, thirty-three and a half being the proportion of sickness among 100 paupers.

urged in favour of parties finding their own drugs, another reason occurs to me, viz., that those surgeons who do not dispense medicine, will thus have it in their power to accept of medico-parochial appointments. I am, Sir, your obedient servant,

J. C. YEATMAN.

Frome, Somerset, Feb. 12, 1836.

THE LANCET.

London, Saturday, February 27, 1836.

THE public mind has once more received a terrific shock in consequence of the fatal catastrophe which has just followed another infliction by the cat-o'-nine-tails, on the back of a marine in the barrack of Woolwich.

But was the flogging the cause of death? The medical witnesses who were examined at the inquest think that it was not. Eight of the jurymen were, in the first instance, of a contrary opinion, but a majority of that body ultimately decided, that "the unfortunate man died by the visitation of God, and not by the hands of any person or persons whatsoever." This is the verdict. But whom will it satisfy? None but the advocates of human torture. None but the admirers of a brutal system of treating the soldiers and sailors of this country.

Some of the facts of this case we can state from personal observation. When it was stated in the *Weekly Dispatch* of Sunday the 21st instant, that another unfortunate criminal had been flogged at Woolwich under very distressing circumstances, and when we farther saw, on Monday last, that the victim of cruelty had ceased to exist, and that an inquest was to be held on the body on that day, the Editor of this journal considered that as a member of the medical profession, and as the occupier of a seat in the Legislature, it was his duty to see the body of the deceased, and to inquire personally into the circumstances of the case. Accordingly he proceeded to Woolwich,

on his arrival at two o'clock, he was not a little astonished to hear that the inquest after the jury had been sitting for about an hour and a half, had adjourned to the following morning, to be again resumed at nine o'clock. On repairing from the *Ship Tavern*, where the coroner and jury had met, to the Infirmary of the barracks, we were at once admitted to a view of the body. No attempt was made at concealment, no desire was manifested to misrepresent the details,—none to withhold the knowledge of a single fact from any inquirer. The conduct of Mr. PARKIN, the chief-surgeon of the barracks, was not characterized by the slightest reserve, and his conduct clearly manifested that he had in all respects discharged his duty to the sufferer. The advocates of the flogging system cannot, in this instance, cover the disgrace of the fatal event by accusing the surgeon of neglect, or the absence of a knowledge of his profession, or of unkindness of heart; and both the relatives of the unfortunate soldier and the public may be assured, that all was done in the Infirmary of the barracks, that could be accomplished by medical skill and humane attention, to divert the catastrophe which followed the flogging.

As the young man had died only on the previous morning, the body was perfectly fresh, and no sign of disease appeared upon it, from head to foot, except in the remains of the cruel blood-red wounds (which were situated immediately over the spinous processes of the dorsal vertebrae), and in the inflamed surface by which those wounds were surrounded. So far, therefore, as external appearances were concerned in viewing the body, the only evidence of disease was observed when the treatment of torture had been applied. It was prudently determined, therefore, by the jury, that an examination of the internal organs should be instituted, and the inquest had adjourned a short time before we reached Woolwich, for the purpose of having the body executed.

It was agreed, we understood, that the examination was to be conducted by the barrack surgeons, by Mr. BURRIS (the parish surgeon), and Mr. GRAINGER, of the *Fleet Street School of Anatomy*. Unfortunately, we were prevented from attending the adjourned inquest, but a brief report of the proceedings was published in the *Times* of Wednesday. As no contradiction of any portion of that report has since appeared in the journal in question, we may, we suppose, take it for granted that the abridgment of the testimony has been correctly given. On looking at the list of medical witnesses, however, we find no mention made of Mr. GRAINGER. We are the more surprised at this circumstance, because, on returning from Woolwich, we met Mr. GRAINGER travelling in the direction of that place, and his private residence is situated within a very short distance from the barracks. We ask, then, was Mr. GRAINGER present at the post-mortem examination, and if so, why he was not questioned in reference to the comparatively inexperienced and unknown Mr. SAMUEL SOLLY? and who were the medical witnesses on the occasion? Mr. PARKIN, surgeon of the barracks; Mr. JAMES LAWRENCE, a naval surgeon, who was sent down by the head of the Navy Board; Mr. BUTLER, the parish-surgeon, of whom we have heard it said that he is not unfavourable to the punishment of flogging; and Mr. SAMUEL SOLLY, a young person employed in the dissecting-room of *St. Thomas's Hospital*, whose reputation as a pathologist has yet to be tested.

After the medical testimony had been given, eight of the jurymen declared that they were of opinion that the death was produced by the flogging, but the other nine jurymen, after returning a verdict of acquittal upon the medical evidence, and at last the verdict which we have above written was recorded.

As the medical witnesses may allege that their evidence has not been correctly re-

ported, we shall not insert any portion of it on the present occasion; but shall wait until we can procure an official copy of the testimony, through the instrumentality of a motion in the House of Commons, and an order from the Crown. As the report, however, in the *Times* agrees throughout in stating that the medical witnesses all concurred in declaring positively, that the flogging was not the cause of death, but that the man died from the effects of a fever, and that the fever was the product of some foulness of the air, or of the earth, or of the waters under the earth, we cannot refrain from saying a few words on this part of the subject. We must tell these gentlemen, therefore, at once, that their opinions are unsound and unphilosophical, and utterly at variance with those of every esteemed writer on morbid anatomy, and if such evidence—if such nonsense can be termed evidence—were generally received in our courts of judicature, the science of medicine, and even medical practitioners themselves, would be converted into objects of scorn, derision, and disgrace.

Observe. The only apparent cause of the fatal calamity,—the only cause which was subjected to the operation of the senses,—is discarded by these acute practitioners and witnesses, in order that, like so many ghosts, they may spirit themselves into the air, earth, and water, to discover, in absurd conjectures and wanton hypotheses, a reality which they have not the sagacity to detect in a plain matter of fact. What was the state of the health of the man when he was flogged? It was sound and excellent. Nay, it was alleged by all who knew him, that he was in rude and robust health. He was in this state on the 8th of February, the day on which his back was lacerated. On the 20th he was a corpse. Now mark. The medical witnesses are not content with merely saying that they cannot discover the cause of death on inspecting the body, but they take upon themselves to say that the flogging was not the cause of death! Ab-

surdity can go no farther. If in such a case they be incapable of maintaining the affirmative proposition, how can they prove the negative? We will not say that such conduct is dishonest, but we cannot refrain from alleging that it is most mischievous. Ah, had there been a medical Coroner in this case, we will undertake to say that the public mind would not have been shocked by such a verdict as has been recorded by the non-medical Coroner for Surrey.

On the 8th of February, then, the day of the flogging, WILLIAM SAUNDRY was in a sound state of body, and when we saw the corpse, on the 20th instant, the day after his death, the blush of health was still apparent on his cheeks, and, as we before stated, there was no emaciation, no sign of disease or injury, except upon the back where the horrid punishment had been inflicted. The cat, as is well known, consists of nine strings of cord, with knots in each string, and a hundred strokes from this infernal machine, would necessarily produce nine hundred cuts on the skin. And on what part of the body was this dreadful punishment inflicted? Why within a few inches of the brain, the great centre of the nervous system, and directly over the spinal marrow, whence so many nerves essential to the existence of life originate. Good God! The shock which the whole system must receive from the infliction of such torture would be enough to kill the hardiest, the least sensible, of the brute creation. Now, did the medical witnesses cut down through the skin at that part? Did they cut through the bodies of the vertebræ and examine the spinal chord and the membranes immediately under the wounds in the back? If they did make such an examination, how is it that the report in the *Times* makes no mention of it? And if they did not, how can they dare to allege, in the face of the profession and the public, that the flogging was NOT the cause of death? If they did not examine the state of the spinal marrow,

we tell them that their investigation was worse than useless. It was only calculated to delude. Do these gentlemen believe that the skin covering the spinal marrow may be cut, bruised, and lacerated, with perfect impunity? Do they think that there is no sympathy between the skin and the nervous system under such torture? Impossible! Their own every-day treatment of affections of the spinal marrow proves directly the reverse. They cup, blister, leech, and canterize the skin immediately where the scourge was applied in the instance before us, to relieve inflammation and other affections of the spinal marrow, and the membranes of that important structure. The bite of a leech, or a bit of blistering fly, can operate on the spinal marrow, but nine hundred cuts and jags in the same situation cannot produce trembling in a single fibre of the nervous system! Oh this monstrous mockery of the unerring principles of the science of medicine! Will these medical practitioners deny that the prick of a pin in the finger, that a fibre of wood in the same part, will often so affect the nervous system as to produce locked-jaw and death? But there is a case, of recent occurrence, quite to the point. What was the cause of death in the case of the unfortunate Miss CASHIN? The application of a stimulant lotion to the skin in the very situation in which this poor soldier was flogged. There was no wound in the back of that young lady. Yet she was literally stung to death by the caustic lotion, and the stings which the soldier received were scarcely less poisonous or severe.

When we are placed in possession of an official copy of the evidence taken at the inquest on the body of William Saundry, we shall return to this painful subject, but in the meantime, we do trust that the English nation will call, as loud and true, for the abolition of the brutal system of flogging, as it is practised in the British army and navy.

CONTRARY to the expectation of the Ministers themselves, the charter for founding the Metropolitan University was not completed by the 24th inst. The arrangements, however, are sufficiently advanced to admit of the choice of a Chancellor, and Lord BURLINGTON, who was a senior wrangler at one of the English Universities, and is distinguished for his literary and scientific attainments, will be the first individual appointed to fill that high and distinguished office.

SINGULAR CASE OF DOUBLE VISION.—At the *London Medical Society* on the 22nd inst., Mr. FIELD related a remarkable case of double vision, which in some particulars differs from the usual symptoms of such affections. The patient is a young man, aged 22, of abstemious habits, and so studious in playing and writing music, as frequently to lose a great portion of his night's rest. He first began to see objects double about two years ago, but he did not pay any attention to the circumstance. Since then the affection has continued to increase, and he now sees two distinct objects, one a few inches above the other; that which he takes to be the real object, appearing rather the brighter of the two. It is only at a certain distance that he experiences this phenomenon. When near, objects are not doubled. There are no symptoms of disease of the brain. The eye is dark, and the pupil does not contract to the usual extent of healthy action. What is most remarkable in the case is, the fact of both eyes being similarly affected; so that if the patient closes either, the same result follows as when they are both open. Various opinions were expressed in the Society with regard to the cause. Mr. KINGDON thought that the habit which the eye had acquired of looking at two bars of music at once, together with the abstemious habits of the patient, might have had considerable influence in the production of the disease. Mr. PILCHER considered it either to be the result of incipient amaurosis, or an irregular action of the muscles of the eye. Mr. DUNN, the President thought that the cause must exist in the ball of the eye itself, some alteration, perhaps, in the humours. It was the general opinion of the Society, that the great application to music should be at once dispensed with by the patient.

DETECTION OF ARSENIC.

After an operation at the *Westminster Hospital* on Saturday last, Mr. W. LYNN exhibited to the students a new process designed for detecting arsenic in "the smallest possible quantity." The fluid supposed to contain the poison is put into a phial containing a small quantity of metallic zinc. Some diluted sulphuric acid is added, and hydrogen, with the arsenic, should any be present, is evolved. A small glass tube, inserted into the cork of the phial, gives exit to the gas which is ignited, and a glass receiver is held over the flame. The hydrogen mixes with the oxygen of the atmosphere, and forms water, while the arsenic is deposited in its metallic state on the sides of the receiving vessel.

[Might not this test in many instances be fallacious, from the fact of zinc frequently containing arsenic?—*REP. L.*]

ANTIDOTE FOR THE POISON OF MORISON'S PILLS.—At the close of an eloquent and excellent expostulation on the folly of yielding credence to the falsehoods promulgated by the dealers in quack medicines, for which, however, we are unable to find room, a correspondent adds the following statement:—"I wish to make known generally, for the use of those who are guilty of the folly of habitually taking the Morison's pills, that the best means to be adopted to relieve the distressing vomiting and purging which frequently follow their employment, consist simply in taking copious draughts of lukewarm water (in the case of sickness) to assist the stomach in its attempts to dislodge the poison, and mucilaginous and gelatinous drinks, such as barley-water, linsced-tea, mutton and chicken-broth, will mitigate the severity of the purging, and afford some protection to the internal coat of the intestines from the acrid and irritating effects of the gamboge, aloes, and colocynth, which are found in the pills." Our correspondent most justly remarks that until the practices of quack doctors and the use of patent medicines are interdicted by Parliament, medical science can only be a by-word with the public, as astronomy formerly was disgraced by the connection of astrological conjuration with its observations and study.

ANATOMY IN IRELAND.

THE following official letter has been lately addressed by the Inspector of Anatomy in Dublin, to the Right Hon. Lord MORPETH, Secretary for Ireland:—

Office of the Inspector of Anatomy,
Dublin, Feb. 1st, 1836.

MY LORD,—As Inspector of Anatomy I have the honour to submit the return and report for the quarter ending this day. During the last three months the number of subjects sent to the schools, exceeds that sent during the entire of the year before last.

An attempt was lately made to revive the revolting practice of exhumation. Two of the party were sent to Newgate. Afterwards thought it prudent to permit them to join the Queen of Spain's troops, with their ringleader Malone (whom I had formerly convicted). Thus has this gang of desperadoes been transported with their own consent.

I am happy to acquaint your Lordship that the advantages presented to the Students of Anatomy in Dublin, are now equal to those of any other part of the world. The supply of subjects is regular without conflict, and abundant without outrage to public feeling, as formerly. The gratifying testimony to that effect of the Professors of the eight schools of Dublin was published in *THE LANCET* of March 14, 1835.

The approbation expressed by the Dublin Professors has been further confirmed by the annexed testimonial from a very influential public body. The Inspector has only endeavoured to carry into effect the enlightened intentions of our liberal Government. I have the honour to be, my Lord, your obedient servant,

JAMES MURRAY, M.D.,
Physician to the Lord Lieut. of Ireland.

ROYAL BELFAST ACADEMICAL INSTITUTION; Joint Boards of Managers and Visitors, Feb. 2, 1836; Extract from the Minutes.

Resolved Unanimously,—"That the thanks of the Joint Boards are due to Sir James Murray, Inspector of the Schools of Anatomy, for his uniform attention to the interests of the Anatomical class of this Institution.

JOSEPH STEVINSON, *Secretary*."

MEDICAL CORONERS IN IRELAND.—*To the Editor*.—Sir,—In compliance with a desire expressed in a late number of *THE LANCET*, I herewith send you a list of the Irish medical coroners, with their places of residence, taken from Pettigrew and Oulton's "Dublin Directory" for this year. I am, Sir, your obedient servant,

JOHN BROWNE, M.D.
25, Holles-st., Merrion-sq., Dublin;
20th Feb. 1836.

Cavan, John M'Fadden, M.D. (and another), Cootehill.

Down, George Tyrrell, M.D. (and two others), Banbridge.

Dublin, James M'Carthy, Apothecary (and another), Amberg-street.

Leath, Henry M. Blackwell, M.D. (and two others), Danier.

Monaghan, Robert Murray, M.D., Beech-hill, Monaghan.

Wexford, James Hamilton, M.D. (and two others), Gorey.

MR. MORGAN OF GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I shall feel obliged, as will the rest of Mr. Morgan's hearers, by your giving insertion to the following statement, though it is with extreme reluctance that I make any complaint on the subject. I do, however, most justly find fault. The apathy, disrespect, and apparent indolence, of Mr. Morgan towards his pupils, compel me to adopt this mode of troubling you for a small space in your valuable publication. Mr. Morgan announced at the beginning of the session that his lectures on ophthalmic surgery would be delivered on every Thursday evening, but after the first three lectures Mr. M. seldom has appeared for any two weeks consecutively. Consequently, he lately had to announce that, unless he lectured three evenings a week, it would be totally impossible for him to complete the course ere the middle of June, but if the pupils would listen to three lectures per week he could terminate the course by the end of March, and, as he did not feel particularly anxious to lecture to empty benches, he hoped that some gentleman present would take the sense of the meeting and communicate it to him in the museum, where he would await the proceeding, which ended by a great show of hands in favour of three lectures being given a week. Yet Mr. Morgan has not given a lecture on a Thursday evening since, which will be three weeks up to Thursday, February the 4th. Mr. M. cannot have had the interest of his pupils in view by this neglect; he evidently has thought that he might neglect them at his pleasure. I shall forbear saying more at this time, awaiting some apology from Mr. M. at his next lecture, or the strict deliberance of the three as arranged. Mr. M. must be well aware that his pupils have had to arrange their time for the three evenings, and most likely have some other lecturer, in order to attend according to his new arrangement. My name and address are at your service. I am, Sir, your obliged servant,
H. D. E.

February 1, 1836.

COLLEGE OF PHYSICIANS

THE LAST HALIFORDIAN LECTURE.

To the Editor of THE LANCET.

SIR,—On Monday evening last I was introduced as a visitor at the first dinner for the season, of the College of Physicians, and as I am but little accustomed to such proceedings—at all events have not been made insensible to their improprieties by habit—and being, moreover, personally uninterested, and, therefore, it may be presumed, an impartial observer, you will perhaps favour me with an opportunity of stating what impression was made upon me by the scene. In doing this, if any one should think me an uncourteous guest, I would simply say, that I make no scruple in sacrificing courtesy to justice and professional usefulness, when both happen to be incompatible. There were present, as I am told is generally the case at their first meeting, a number of distinguished individuals,—the two archbishops, several bishops, the premier, and some other leading political characters. Two things, above all others, awakened my reflection, viz.—the conduct of the President as an individual, and that of the College as a body. The president delivered an oration on the death of some individuals who were distinguished for their attainments in science, Bacon, Boyle, Newton, Locke, Addison, Johnson, and Sir W. Jones. It contained a brief account of the circumstances attending the death of those eminent men, and a more particular description of their moral and religious characters. They were held up as examples to stimulate our virtue, and to strengthen our confidence in the faith we have adopted. From this account the discourse would appear to be sufficiently appropriate,—for I think on such an occasion it should not be wholly unprofessional, nor on the other hand so technical as to be uninteresting to the non-medical guests. But the mode of its execution removed from my mind every favourable impression made by the plan, and substituted in its place a feeling, deep and unmingled, of disgust and abhorrence. My object, Sir, is simply to express my feeling, not to prove it to be just, for that could not be done to one who did not witness the exhibition, and as those who did, I am sure it need not. The manner of this discourse then convinced me, that what the president did not care to say to the students, he was determined to mix with the public about it with every sentence he uttered, and that he therefore made a parade of religion for unworthy worldly purposes, as one who professes to respect real religion. I was almost choked with disgust at this apparent mockery of a sacred theme. I think it an indelible stain

upon the religious character of this age and nation, that any man should dare to deliver such a discourse in the presence of the leading men of the church, and of a liberal and learned profession. Yet all this is done by the nominal head of the medical profession in England, the chief official medical attendant of the monarch. Can it be true also that he has acquired this station more by this and similar practices than by the exercise of any solid, to say nothing of sacred, attainments in his profession?

The second matter which arrested my attention was the separation of the fellows from the licentiates. The upper part of the room was barred off, for the exclusive use of the president, the fellows, and the titled guests. Over the other parts wandered the licentiates and the minor attendants! To argue that the fellows were thus set apart for their merit, is to outrage truth most grossly. If a man has been at Oxford or Cambridge, though he may have spent his time in every species of hypocrisy, blackguardism, and debauchery, he may become a fellow of the College. It is useless to allude to individuals, the principle being the important thing; but on this occasion I saw, amongst many other men equally worthy of being mentioned, the vice-president of the most learned society in Europe, thrust as a licentiate among the lower ranks, like a boy in a booth, to stare at the show prepared for view in another part of the room. How can such an impudent and degrading system be tolerated even for a single moment. Finally, Sir, I am astonished that the licentiates will go to the College at all. They should stay away in a body, and thus diminish the number of gazers. I am, Sir, your very obedient servant,

OBSERVATOR.

London, Feb. 23, 1836.

DR. W. CUMMIN.—MR. EDITOR,—However contemptible your opinion may be of those individuals who contribute to a journal whose main object ever has been to traduce the character of the general practitioner, and to libel the students, it is monstrous to suppose that Dr. Cummin should come forward and publicly deny that he was not the coadjutor of Dr. Rod. Macleod. Permit me to ask if it be not a fact that the papers read before the Medical and Chirurgical Society are instantly sent to Dr. Cummin for the sole and avowed purpose of enabling the said Dr. C. to make such extracts and abstracts from them as he may, in his wisdom, think fit for insertion in the Gazette. Should you have any doubt of the truth of this statement, let me refer to Messrs. Glendinning and Partridge, the present Secretaries of the Society, or their predecessor, who has himself become so expert in mak-

ing "Elegant Extracts," and by whom these arrangements with the Gazette were originated. I am, Sir, your obedient servant,
A FELLOW OF THE SOCIETY.
Feb. 22, 1836.

with a coronet upon it, and livery servants behind, whose outer coats showed much better than other portions of their dress. I am, Sir, your obedient servant.

OBSERVER. •

Dr. W. CUMMIN.—To the Editor.—Sir,—Something more ought to be made known with regard to the expostulatory letter addressed by Dr. Cummin to you respecting the secret editors of the Medical Journal. Notwithstanding the statements therein made and conjointly testified, I understand that the gentleman who questioned Dr. Cummin, positively declares that Dr. Cummin did deny to him in explicit terms that he had any thing to do with the editing of the Gazette. Dr. Cummin it is thought was alarmed into telling this story by the momentary fear of avowing the connection, but having gathered courage afterwards when he saw the statement in print, he denied that he had ever disavowed the connection, because his acquaintances would have thought worse of him as denying what was so notoriously true, than they even did for his hiring his time and services to Dr. Macleod. This is the report. The student, I understand, was warned not to question Dr. Cummin without having by him an independent witness, but he was too unsuspecting to take the advice. However, he came straight out of the room and told to every one around exactly what appeared in the letter in your journal. I am, Sir, yours obediently,

W.

St. Bartholomew's, Feb. 19, 1836.

QUACK PILL ADVERTISING.

To the Editor of THE LANCET.

SIR,—You mention that you shall speak further respecting the late murder by Morison's pills. I was induced the other evening to visit Exeter Hall for the purpose of hearing a Dr. Lynch lecture on hygiene. Morison himself, I believe, was on the platform. Between two and three hundred supporters of the system were present, and applauded to the echo the attacks of this "Doctor" on the profession. His subject was apoplexy, and he misquoted a number of great authorities to prove that they decided on condemning bleeding under any circumstances in that affection. His lecture was a tissue of absurdities and abuse. He spoke of the late murder, and said the victim was doing well until the "Doctors" were called in. He afterwards left the Hall in a carriage, which had, evidently for effect, been placed at the door for a long time before,

LATE ADDRESS TO APOTHECARIES' HALL.

To the Editor of THE LANCET.

SIR,—From the zealous and able manner in which you have uniformly advocated the rights of students, I feel it a duty to apprise you of any circumstances connected with the subject.

I see on the cover of the last week's LANCET, a number of names of students at the London University, who affirm that they were opposed to, and had nothing to do with, the meeting at the Crown-and-Anchor; at the head of the list is a Mr. LEGGATT, who is a pupil of that very courteous functionary, Mr. Secretary WATSON. Doubtless this Mr. LEGGATT will be recompensed for the pains he took, during three or four weeks, in endeavouring to collect a tolerable list of names for the support of his master's interests. I need hardly say, Mr. Editor, that the greater part of these honourable and liberal minded students, in a short time, intend to present themselves for examination at the Hall in Blackfriars; and I have no doubt that this mean-spirited publication of their names, is designed to act as a demulcent on the surly growl of a WHEELER, or a RIDOUT, or to restrain the annoying gesticulations of a MERRIMAN. I am informed, on the authority of a student who was present at the first meeting at Anderton's Hotel, that not a few of these celebrated gentlemen took a prominent part at that meeting, and even wished to become proposed as members of a committee for conducting the succeeding meeting at the Crown-and-Anchor. A Mr. BRIGHTMAN was very conspicuous on the occasion. So much for the firmness of the students at the London University. I consider this proceeding a most unjust one towards all those gentlemen whose names have not appeared in the list (many of whom have taken neither side of the question), inasmuch as of course they will be considered at Apothecaries' Hall as having approved of, or taken a part in, the meeting. I am ashamed of such conduct in medical students, and regret that the character of the London University has been tarnished by the selfish feelings of a few interested persons, operating on the fears of their fellow students. I remain, Sir, your obedient servant,

A STUDENT OF MEDICINE AT THE LONDON UNIVERSITY.

February 23, 1836.

LATE ADDRESS TO APOTHECARIES' HALL.

To the Editor of THE LANCET.

SIR,—I entreat you to extend your kindness to me who earnestly desires to make known the fact, that there are yet many scores of medical students at the London University, who have not disgraced their names by signing the cringing indirect petition to the Apothecaries' Company, allowed by you to be advertised last week. The professed object of the advertisement is perhaps without parallel in the way of *excuse* for its appearance. The petition is said to be got up to negative a *pretended* report, that the students of the University organized the late meeting at the Crown-and-Anchor. But it is really designed to furnish the Apothecaries' Company with a list for reference in case its favour should be necessary during some future examinations. How disgraceful thus to follow the example of the agents of the Apothecaries' Company at *King's College*! And, worst of all, to attempt to betray those fellow students who, from motives of conscience, refused to place their names among those of the frightened memorialists. When I entered my name as a student in medicine at the *London University*, I did so partly in consequence of the liberal principles on which the school is founded, thinking to enjoy the society of students whose minds and actions were far above those whom I had lately quitted. I sought the companionship of independent men, men with higher characters and objects than might be cherished elsewhere. How miserably am I disappointed on finding, in a moment, that I am among so many who profess liberal principles only as a *matter of convenience*! The petitioners, too, have prostrated themselves at an age when the mind is more usually moved by generous and bold impulses. The proceeding might have been excusable in weak old age, whose long experience too often brings timidity, but for men who are beginning life, it is a sad commencement. You, Sir, whose constant kindness to the *London University* can never be repaid, are willing to ascribe this silly act to the fears of youth, but there is an armour which students may put on that is proof against intimidation, and he who wears it need not be a veteran.

If the students of the London University hold opinions which are adverse to the present medical regulations, whether agreeing or not with the *Medical Register* at the Crown-and-Anchor, they should, without resort to other schools, to declare them frankly, and not merely say, "We disclaim, &c." what others have done. How poor and how feeble is the declaration, and the more so from the great length of time which has elapsed, before these feeble sentiments could be forced

to an announcement! Change of individuals alone can change the public opinion of the students of the London University, so fouled by this advertisement. Allow me, Sir, in conclusion to add, that the advertisement has completely marred the expectations of those who watched with pleasure the increase of our *liberal* school. The ignominious stain time alone can remove. Your obedient servant,

A STUDENT IN MEDICINE AT THE
LONDON UNIVERSITY.
London, Feb. 22, 1836.

LATE ADDRESS TO APOTHECARIES' HALL

To the Editor of THE LANCET.

SIR,—The document published on the wrapper of the last LANCET, is remarkable from more causes than one. The first name that appears in the list is that of Mr. LEGGATT, the late apprentice to Mr. WATSON, the secretary of the Society of Apothecaries. The fourth name, that of Mr. AYRES, is that of one who is already known to the Court of Examiners as being connected with a botanical prize, and who thus expresses his gratitude for the gift. The name of Mr. A. TIBSON, a little lower down, is that of a student who received a similar honour. He, too, thus repays his gift. Several other names are those of apprentices of Examiners at the Hall, or of persons who are particularly interested in the welfare of the Company, and these gentlemen have been the indefatigable agents and promoters of the address. They have left no stone unturned to get names to prove—that it is time that the examinations for diplomas were made public! I am, Sir, your obedient servant,

AN UNIVERSITY STUDENT.
Feb. 23, 1836.

To the Editor.—Sir,—Permit me through the medium of your valuable journal to respectfully recall to the recollection of Dr. Quain, an assertion contained in his prospectus, issued precedent to the publication of the first division of the series of "Anatomical Plates illustrative of the Structure of the Human Body;" viz. "The work is in such a state of forwardness, as to ensure a regular publication; a fasciculus will be ready for delivery every fortnight on the 1st and 15th of the month." Need I add that the promise has not been fulfilled? It is not the opinion of one individual, but the united opinion of many, that the future fate of the work mainly depends on a speedier publication, for this reason,—that numerous per-

women have relinquished the work, fearing that the several divisions will never be completed, and that dependent on its present slow publication, by hastening which Dr. Quain would confer a great obligation, not only on the numerous class of medical students, but on medical men generally. I am, Sir, your obedient servant,

A MEDICAL STUDENT.

London, February 23, 1836.

WESTMINSTER MEDICAL SOCIETY.

Saturday, Feb. 13, 1836.

Dr. ADDISON in the Chair.

THE amount of the Society's funds was announced this evening, and it appeared that they were at a low ebb compared with the funds in hand in the preceding year, the difference arising from the small number of new members this session.

Dr. JOHNSON detailed some further particulars of the case of affection of deglutition and articulation reported in a late Number. The patient was better to-day; the stomach can receive, without much inconvenience, double the former quantity of broth. When injections of broth were administered, although opium was mingled with them, attempts at vomiting had generally followed, but not when the broth was passed into the stomach. The system still, as before, retained the nutritious portions of food, and when vomiting took place, all but the nourishing parts were ejected. The pulse, however, gets weaker, and her strength decreases. He proposed to pass the electro-galvanic shock from above downwards, in front, along the course of the eighth pair of nerves, which he believed were implicated in the disease.

Mr. STREETER inquired whether apoplexy during pregnancy was likely to affect the child, and whether utero-gestation proceeded after an attack.

Dr. UWINS supposed that apoplexy was of rare occurrence during pregnancy. He regarded the pregnant condition as desirable to the female who was predisposed to apoplexy.

Dr. RYAN related a case of pregnancy, accompanied with apoplectic symptoms,—the pregnancy eight months advanced; but the patient was predisposed to cerebral affection, and the attack was induced through taking twenty-five drops of laudanum, which led him to regard it not as a genuine case of apoplexy occurring during pregnancy. A practical point, of considerable interest in a medico-legal sense, was that the delivery was accomplished during the state of insensibility.

Mr. STREETER said that he also thought

that genuine apoplexy during pregnancy was rare. The following case happened within the last five weeks. The apoplectic seizure was followed by hemiplegia; the woman was three months advanced, and in the thirty-third of her age. The influence of these attacks in bringing on delivery he believed to be considerable. This woman had had three miscarriages and two premature labours. Notwithstanding the present attack of apoplexy, gestation was proceeding normally. The paralysis of the left leg, which was complete, has in some degree subsided, but the arm of the same side remains permanently affected. Consciousness existed up to the time of the attack. The approach of the fit was manifest to a child, by an alteration in the voice, and a particular appearance of the eyes. The sufferer said she felt cold and faint, and experienced a deadened state of the left side. She returned home from a short distance, and ascended a few stairs, but shortly after was found by the servant in a state of insensibility, in which she had remained from ten to fifteen minutes. When somewhat rallied she was bled, and leeches were applied, as she complained of pain over the temples. What was the proper treatment in such a case. Should delivery be encouraged?

The members preferred discussing Hahnemanism, and the question of Mr. Streeter remained unanswered.

Dr. JOHNSON here made some remarks on Hahnemanism, which we reported last week.

Dr. UWINS acknowledged his total ignorance of Hahnemanism, but as some men of acquirements and good character had embraced the doctrine, he thought it ought to be examined before condemnation. No doubt, Dr. JOHNSON recollected when he (Dr. J.) condemned phrenology, which he now advocated.

Dr. JOHNSON replied that he did not advocate phrenology until he had studied it.

A discussion ensued between Mr. STREETER, Mr. KING, and Dr. JOHNSON, with regard to the administration of large doses of tartar emetic, which the two former gentlemen characterized as very dangerous, much mischief being ascribed to the extent to which it was often prescribed. Indeed, remedies in general (Mr. KING thought) were given in much too large doses, and especially those of which we could not pronounce the exact effects and mode of operation. Mr. KING said that he was fully satisfied that more success had resulted from the Broussais treatment than was ascribed to it, and that it was far wiser to act by the milder than on the more energetic plan of treatment. As to Hahnemanism, though it might be safe sometimes, it was not adapted to the treatment of diseases of a grave nature.

At the conclusion of these remarks, which were more interesting to the audience than

we can make any report of them profitable to the reader, Dr. Addison delivered his opinions on Hahnemannism, but of these we have not at present any account before us.

WEBB-STREET SCHOOL.

PRESENT TO MR. GRAINGER.

ON Wednesday last the students at the above school assembled in the Theatre for the purpose of presenting to Mr. GRAINGER a token of their personal regard, and their high opinion of his zeal and abilities as a teacher. The proceedings commenced at one o'clock, when the benches were crowded with pupils.

Mr. CHALDECOTT having been unanimously voted into the chair, briefly and appropriately stated the object of the meeting. Two very highly-finished silver salvers were then brought into the theatre, and exhibited as the intended gifts. Upon the larger was engraved the heraldic arms of Mr. Grainger, with the following inscription:—

“RICHARDO D. GRAINGER,

Viro Humanissimo, præceptori anatomie peritissimo, hoc argentum in diturnum, tum virtutis, tum ingenii, testimonium dono dederunt alumni

A. D. MDCCCXXXVI.”

Upon the other was engraved, “Presented in the Theatre of the Webb-street School of Anatomy and Medicine, to Richard Dugard Grainger, Esq., by his pupils, as a very sincere expression of personal attachment and respect, and in especial testimony of his very high sense they entertain of his zeal and ability as a teacher. Feb. 24, 1836.”

The Committee then waited upon Mr. Grainger to request his presence, which was accordingly acceded, amid the loudest shouts of applause. When the cheering had subsided, Mr. Grainger was addressed by

Mr. BICKERSTETH* as follows:—“Sir, often as you have been welcomed into this theatre, the occasion was never, perhaps, attended with such a thrill of delight on the part of the welcomers. I approach you on behalf of the pupils, to present you with a memorial of their esteem and regard; but honourable as is the task I have to perform, it is one which is attended with no ordinary degree of difficulty. I have myself not had the gratification of knowing you so long as many who are present, but yet long enough to entertain the warmest esteem for your character and exertions in this school. We are met, sir, to offer you a demonstra-

tion of our attachment and respect. I do not refrain from saying much on this occasion because I do not feel much, or because my breast throbs with less intense feelings than move the hearts of those who have deputed me to represent their sentiments. Your presence prevents me from adverting to many things which I should be anxious to say in evidence of my regard for so excellent a teacher, while assuring you of their esteem and respect. Recollecting the circumstances under which this school was formed, and remembering the unparalleled difficulties it has had to encounter, we are persuaded that the undaunted resolution, indefatigable perseverance, and resplendent talents, exercised by your late lamented brother and yourself, could alone have raised it to the eminence which it enjoys, after having crushed the thralldom of monopoly and oppression. (*Loud Cheers.*) Long may it flourish, sir, under your skill and protection, and ever retain its character for industry and independence. It is not my intention, on the present occasion to enter upon a lengthened review of the peculiar difficulties that at one time impeded the onward progress of our profession, but I may perhaps be permitted to remark we are aware of them.—that we are sensible of the extraordinary impediments which were opposed to the exertions of the late respected Edward Grainger, before he succeeded in gathering round him a larger body of pupils than ever flocked to the prelections of any anatomical teacher in this metropolis. But not only did he found a school, which soon became marked for the acquirements of its scholars, but to him may be ascribed the credit of having raised the standard of medical education to a height which it had never before attained in this country. (*Cheers.*) Individually, as a scholar, I feel a debt of gratitude towards him. As a member of the medical profession, I feel it infinitely increased. Would that he could be present! But there is among us one who has confirmed that success which it was to be hoped would crown his labours,—one of his earliest associates in the school,—one who now upholds its reputation with remarkable energy. (*Loud cheers.*) To him, on behalf of the pupils of this school, I beg to express the fervency with which the impression is entertained, and to him,—to yourself, Sir,—our warmest thanks are due. Your unremitting efforts for the welfare and advancement of your pupils demand this from them. The merits of the school do not consist in the magnificence and stateliness of its walls. (*Hear, hear, hear.*) To its internal arrangements are the honours which attend superiority due; and, in this respect, the school of Webb Street may proudly lift up its head as high as that of any school in the metropolis, and no title among students

* This gentleman is, we believe, the nephew of Lord Bessborough, the lately appointed Master of the Rolls.

can rank higher than that of being under the instruction of a Grainger, a pupil of this school. (*Loud cheers.*) With the earnest hope, sir, that you may long be spared to enjoy the success of your exertions in the growing advancement of the institution, and that it may be an important place of instruction in the new Metropolitan University, I now, on behalf of your admiring pupils, solicit your acceptance of these memorials of our esteem, attachment, and respect. (*Great cheering.*)

Mr. GRAINGER, amid a repetition of the cheering, then addressed the class.—Although, gentlemen, he said, I cannot plead the excuse that I am unaccustomed to address a public assembly, and still less an assembly in this theatre, where, at all times, I have been received with the strongest proofs of attachment from my pupils, yet, the present occasion, I assure you, finds me at a loss to express to you the feelings of gratification under which I labour. But I will not, with the vanity which is so inseparable from our nature, attribute all the kindness you have this day manifested, to mere personal motive, but to higher and more distinguished objects. In this institution I have aided in the establishment of a system in which the teachers, trusting solely to their own merits for success, have met with the reward which usually attends indefatigable industry, and to the influence which this school has consequently had in promoting the general welfare of the medical students in this metropolis, and the improvement of medical education generally, do I chiefly ascribe the possession of those honours which have been conferred upon me to-day. This theme is to me more grateful than that of my own humble talents. Few who are now here can tell the condition of the metropolitan schools, or the condition of medical education, when this school was first established. At present it must afford us the greatest satisfaction to see that, in every school in this metropolis, the only rivalry among the teachers is who shall most efficaciously discharge their duties, but there was a day in which the medical student had to look rather to his own unaided and unguided exertions than to any benefit he could hope to receive from his instructors. (*Hear, hear.*) There was not then, in this great metropolis, probably more than one teacher employed in communicating a knowledge of practical anatomy to a class of from three to four hundred students, and you who are employed in the active study of your profession must be aware how utterly incapable one individual would be to afford instruction to so multitudinous an assemblage. The students were entirely thrown upon their own resources to obtain that acquaintance with the human body which is so indispensable to the safe practice of their profession. You will judge, then, what medicine owes to the

founder of this school (and in the benefits of which I myself have greatly participated), who sunk into an early grave, the victim of industry in the cause of science. I gladly avail myself of the opportunity of thus publicly recording the debt of gratitude which I myself owe to my lamented relative, and to point out the claims he had on your admiration as the founder of this school. I can hardly describe the difficulties which he had to meet—offered to his progress by opponents who ranked among the first men in the profession, and his competitors were no less in station than a Cooper and an Abernethy. Yet not only did he establish the school, but he acquired for it in five years the highest reputation, and he had assembled around him, unaided by the slightest extrinsic agency, a larger class than had ever before attended the most celebrated teacher of this or any other metropolis. I lately had occasion to send to his Majesty's Government an account of the number of students who attended his lectures, and I confess to you, that although I was aware that their numbers were very great, yet, so many years having elapsed, upon referring to the book in which these, in some degree, sad memorials, were recorded, I was surprised to see the immense number to which they reached. Gentlemen, my only claim upon your kind feelings arises from the circumstance that I have, in some degree, with the assistance of my able colleagues of that and subsequent periods, maintained the success and reputation of the school. (*Hear, hear.*) I mentioned to you, gentlemen, that when this school was first instituted, the profession of teacher was in a very few hands, and the system allowed them all to be appointed through the means rather of family connection and influence with powerful corporations, than any intrinsic merit of their own. Not that I wish in the least degree to reflect upon individuals. I speak of the system, and say, without the fear of contradiction, that the plan at one time was to adopt only those teachers who had the strongest recommendations from relations, and who could catch the ear of those who had the bestowal of the honours of the profession in their hands. (*Hear, hear, hear.*) Observe the contrast now. It is not from the name of an institution; it is not on the score of its wealth that success is to be found. The present age looks more to acts than to professions, to men than to institutions. (*Hear, hear.*) I would ask those who have watched the progress of medical education, and attended to the gradual improvements which have been introduced into the several schools of this metropolis, whether they have not originated from the talents, the services, and the unabated exertions, that were employed in the founding of this school? Not that my brother was the creator of those

principles which are now in operation. He was merely their representative. With regard to myself, gentlemen, at the time when I was called upon to fill the office which I now hold, I was in many respects unfitted for its duties. I was unprepared by previous education; but I studied unabatingly to enable me to contend against that opinion which my brother experienced in all its virulence. I make no personal reflections; but when we are considering the acts of public bodies, we are justified in employing the utmost scrutiny, and if they deserve it, in visiting them with our reproach. It has been for years my object to avoid every thing like personal reflection on the conduct of my competitors, but I will boldly assert that some of the corporate bodies of our profession left no efforts unturned to suppress this school, and, gentlemen, the attempt was energetically made by the College of Surgeons against myself. Through me they wished to suppress freedom of instruction, and the independence of the medical student. Yet you, who are the junior members of our profession, have as great a right to choose who shall be your instructors as the first persons in the land. (*Great cheering.*) The attempt, however, was made to suppress every private medical institution in this metropolis, and so to limit the choice of the student as to where he should receive his education. Within six months from the period of my brother's death—aye, within three months—the Council of the College of Surgeons of this metropolis issued a series of regulations, in which they stated that they would not receive certificates of attendance upon lectures delivered in any private school, unless that school could obtain the recognition of one of the metropolitan hospitals, thus throwing the guardianship and the rights of our profession into the hands of the hospital surgeon and physicians of this metropolis. Ought the College of Surgeons to have bestowed the power of crushing private institutions on rival bodies in the public schools? Governing bodies should retain to themselves those discriminating powers which, when justly and honourably applied, no one could complain of. I will just state how far these regulations were aimed at myself. The College of Surgeons not only would not recognise any private school, unless it had previously received the recognition of one of the hospitals; but they held a discussion, whether they should receive the certificates of my lectures, although I had already delivered a whole course of lectures in the winter, the certificates of attendance on which had been received by the College of Surgeons, thus intending, by means of this *ex post facto* law, to put me and the school down. I am perfectly justified in alluding to these acts of a public body (*cheers*); but I will make one grateful acknowledgment

to an individual to whom I feel deeply indebted in those transactions. I allude to a highly-distinguished surgeon, who enjoys an European reputation, who advocated my claims when the question came to be considered at the College of Surgeons, and by which means this school was preserved in existence. I allude, gentlemen, to Sir Astley Cooper. (*Loud cheers.*) There was a great discussion in the Council as to the reception of my certificates, and Sir Astley Cooper, as I have heard, strongly advocated the justice of my claims, and it was represented to me that had it not been for that advocacy, in all probability my certificates would have been rejected. This is the only allusion, gentlemen, that I shall make to any individual, and I make this public avowal of the high sense I entertain of his liberality on that occasion with the greatest pleasure. Fortunately the time has now gone by when the acts of a self-elected Council can suppress those principles of medical education which have since extended with such rapidity and power, not only in London, but in almost every considerable town in the kingdom. This opportunity of gaining medical instruction in the country is most valuable to the student. I conceive it to be a point of immense importance that as soon as the whole routine of compounding, and so forth, is understood, the medical student should be initiated into those principles upon which the successful practice of his profession must rest. There is no fear of medical education again retrograding. Gentlemen, for myself, I have been enabled to take but a trifling share in the work, and the difficulties which I have had to overcome have been balanced by many pleasures. I have ever received the warm support of the students of this school in my efforts, and not only in a public point of view, but I am proud to acknowledge that some of the most valuable friendships I have ever formed I owe to my connection with students as a private teacher. I am, too, most ably supported by the talents of my colleagues, and not only by that, but by the strong feeling which has existed in the profession generally, that to support this school was to maintain a great principle. These advantages were quite sufficient aid to my laudable efforts. (*Hear hear.*) Gentlemen, amid so much, which both retrospectively and at present is highly gratifying to me at this moment, there is one circumstance which I confess throws a shade of gloom over this occasion. I am sorry that among my excellent and worthy colleagues I do not observe one here who is as dear to you as he is to myself (Mr. Millard). I have had the opportunity of watching his rising worth, and the happiness of seeing him placed in a situation where his excellence could be esteemed on a larger scale. And I regret that we are

deprived by a melancholy cause of his presence. Gentlemen, I will not trust myself to speak further on this distressing subject. Enough, gentlemen, has been said of myself; too much for the ordinary influence and habits of my mind. I am not accustomed, nor do I wish, to intrude myself on the ground of my own personal value. I would rather look on this costly present as a proof that you admire the system of which I in some measure have been the representative, than as the reward of any exertions of my own. Yet if any labours of mine have in the least degree contributed towards advancing the welfare of the pupils of these schools, if in short I have deserved, as I have this day received, so ample an expression of your approbation, believe me my utmost ambition is gratified.

Mr. Grainger then withdrew amidst loud and long-continued cheering, and votes of thanks were unanimously given to the chairman, and to Mr. Davis, the Hon. Sec., for the able and satisfactory manner in which they had discharged the duties allotted to them.

Those gentlemen having returned thanks the assembly dispersed, apparently with feelings of great gratification at the proceedings of the day.

COLLEGE OF PHYSICIANS.

THE *Soirees* at this medical show shop, inside of which we have once a year just such a display as is made to the gaping multitude outside of Richardson's booth at Bartlemy-fair, were resumed on Monday last, and every exertion was made at this eventful moment to produce such a display as would strike the licentiate populace with admiration of the extent of the worldly connections and influence of Sir HENRY HALFORD, and convince them what folly it was to try to reduce the professional power of a man of genius in the strong hold of a Royal College. The populace came, and we believe were fully convinced both of the absurdity and the impropriety of directing the battering-ram of reform against the walls of a citadel which contained within it such an army of archbishops, lords, lawyers, artists, and eminent fellows, as were found in array on the present occasion. The Emperor NICHOLAS, at Kalisch, had not more cause for, nor found better success in, exhibiting his troops to the view of Europe, than had Emperor HALFORD in

Ball-Mall on Monday night. In fact, the licentiates and subordinates having attended at the review, had the opportunity of scup of tea, and departed with resolutions to abandon the siege. Indeed, what could men even of superhuman courage do in the field against the Archbishops of YORK and CANTERBURY, LORDS BOURNEMOUTH, LANSDOWNE, WESTMORELAND, and MARROWBY, the PRIMATE, LORD SEFTON, SIR MARTIN ARCHER SHEE, MR. GODWIN, and other such powerful medical warriors?

Some considerable time, of course, was allowed to the licentiates, and the top-apothecaries and the top-apothecaries' apprentices who were mixed with the army of licentiates, to contemplate the enemy, and that period was occupied by an oration from his little Majesty, who took the field in person, and occupied the centre of the troops. The subject was wisely and discriminately chosen. *Death* and *immortality* formed the theme. In times of war the hosts of battle need encouragement to fight to the death, unless immortality is the reward. With extreme delicacy and tact, however, the orator avoided a direct selection of illustrations from the military manseums of antiquity, and as the institution to be defended was one of science, he drew his inspiring examples from the last scenes of the illustrious philosophers of the two past centuries,—from the deathbeds of Bacon, Boyle, Locke, Newton, Jones, Addison, Dryden, Johnson, and Pope, who all died "in the purity of the gospel, by whose light," &c. &c. The oration produced its full effect. The orator had taken the pains to learn the oration by heart, for he pronounced it with one eye on the bishops and the other on the ministers of state, wisely watching in their countenances the impressions which his theological topics and his natural eloquence were producing, as the sentences rolled in a beautiful Mosaic stream of mingled English and Latin, from his lips.

Those licentiates who deposited their helmets and coats of mail with the sutlers of the camp, while looking on in the sultry atmosphere, had better luck with them at the retreat this year than in 1835, when such a number were stolen that a great portion of the retiring troops went home almost naked. On this occasion better care was taken, and only a few suits of upper armour were lost.

It is said that the licentiates found the enemy so strong, that in a council of war held the same night at the Athenaeum, it was resolved to make application to a foreign power for intervention in their favour, and that the famous General, BERTIE RICE, of the kingdom of Westminster, has signified his intention to come immediately to their aid with an overwhelming force.

LATE ADDRESS TO APOTHECARIES' HALL.

To the Editor of THE LANCET.

SIR,—Your remarks on the advertisement of the medical students of the *London University*, inserted in your last Number, were—“That you regarded it as an aid of the prayer of the great meeting in the Strand, and as a proof of the iniquitous power and influence possessed by those secret tribunals which can, by exciting the terror of some candidates for examination, exhort such a declaration from so great a number of students.” But, in another part of the article, you stated that these gentlemen formed no part of the meeting at the Crown-and-Anchor. This is a mistake, for a number of the students who have signed that document were present at that meeting, and voted in favour of the resolutions. I have asked some of them, why they signed a paper which stated that they had not had any connection with the meeting, its originators, or its proceedings, when the reply was, “Because I am going to the Hall.”

But, Sir, the advertisement is not solely signed by the medical students of the University. In the list there are the names of gentlemen who are merely general students in the University, and also of many ex-medical students who are now surgeons and apothecaries, having passed both College and Hall. The originators of the document are admirers of the present system of examination, and they used every endeavour to obtain signatures to it, not scrupling to get gentlemen to sign it, who, as I have before stated, are not medical students.—The originators of the document not wishing to pay the expenses of advertising it themselves, and wisely thinking that if they asked for a subscription at the time of asking for the signatures, they would get very few of either, they had recourse to the following manœuvre:—they said not a word about the subscription until they had got all the signatures; then they placed a paper in the beadles room, stating that it was necessary for each gentleman who signed the paper to pay one shilling for advertising it. And by this method they have got a considerable number of shillings. What they intend to do with the surplus I have not. I remain, Sir, yours in haste,
SCRUTATOR.

NORTH LONDON HOSPITAL.

OSTEO-SARCOMA.—OPERATION.

Mr. LISTON removed an osteo-sarcoma-tous tumour from the lower maxillary bone of a little boy aged ten years. The tumour was first noticed about three months since,

after the extraction of one of the temporary teeth which was in a decayed state, and which had given rise to gum-boil. The tumour was on the increase, and being evidently of a malignant nature, it was thought expedient to remove it without delay. It filled the situation of the second temporary grinder, but in its growth had displaced two of the adjacent teeth, occupying about an inch and a half of the alveolar process on the right side. The operation was performed in the following manner:—An incision, commencing a little above the point of the chin, and being carried along the base of the jaw to the angle, in a semilunar direction, the flap was dissected up, so as to expose the bone, and open the membrane of the mouth freely; the mylo-hyoides and other parts connecting the tongue with the inner side of the jaw were then detached, the knife being introduced from without, and guided by the finger of the left hand, introduced into the mouth. The full extent of the tumour being then distinctly ascertained, the first temporary grinder, the permanent lateral incisor, and the first permanent molar teeth, were immediately extracted. A small saw was applied in front and behind the tumour, in the spaces from which these teeth had been extracted, so as to divide the jaw to some extent perpendicularly. A pair of strong cross-cutting pliers were then employed, so as to embrace the portion of the bone to which the base of the tumour was attached. This was easily divided, and the tumour was extracted. The wound was then brought together by two or three points of interrupted suture. The whole proceeding occupied a very few minutes. Mr. Liston afterwards remarked that it might appear to be a severe operation; the suffering, however, was not so great as would be supposed, but all operations upon the jaws had a frightful appearance. He had made the incisions in such a way, that had the tumour been found to involve the jaw more extensively, the whole thickness of the bone, to any extent, might have been extirpated. It was impossible, before the incisions were made, to know the exact extent of the tumour, and he considered it proper to proceed in such a way, in order that, under any circumstances, the whole disease might be removed. Fortunately it was found possible to preserve the base of the jaw. Consequently there would be little or no deformity. The disease he added, was very rare in young subjects, and he never before, out of a number of cases which he had witnessed or treated, had seen it follow any decay of the temporary teeth, or disease of their sockets. The tumour seemed to the touch to be composed partly of soft matter, and partly of bone. It was a “veritable osteo-sarcoma.”

THE

REFORMED MUNICIPAL CORPORATIONS
AND MEDICAL CORONERS.

Mr. GEORGE ROGERSON, Surgeon, of Liverpool, acting on the hint which we lately put forth in *THE LANCET*, has just published "A Letter to the mayor, aldermen, and councillors of the reform corporations, on the necessity of electing medical coroners," in their respective boroughs.

"This," says Mr. Rogerson, quoting from Junius, "This is not the cause of faction, or of party, or of any individual, but the common interest of every man in Britain."

The example set by Mr. Rogerson is excellent and most timely.

GOWER-STREET.—*To the Editor*.—Several students in the dissecting school beg to express their regret (in a form which will perhaps lead to a remedy) that the time of the demonstrator should be so much occupied with pursuits which prevent him from giving to the instruction of the pupils all that attention which he formerly devoted so exclusively to his important duties. [Our correspondents should have stated the name of the demonstrator. Complaint should be made in the quarters whence the appointment is obtained.]

SIR CHARLES CLARKE, we are happy to be able to state, is one of those distinguished individuals whose name is to be placed on the list of Metropolitan University Commissioners. His liberal principles and his being altogether unconnected with any school or intriguing faction, eminently qualify him for this distinguished honour.

(*From a Correspondent*).—Dr. W. CUMMIN, in deference to the exasperated feelings of the students and general practitioners, is about to relinquish his connection with the Aldersgate-street school.

A Report on the Medical Management of the Native Indian Jails throughout the Territories subject to the Governments of Fort William and Agra, with some Observations on the Principal Diseases to which Native Prisoners are liable. By James Hutchinson, A.M., M.R.C.S.L., and Sec. to the Med. Board of Bengal. Thacker, Calcutta; and Parbury, London; 1836, 8vo., pp. 107.

An essay on the Laryngismus Stridulus, or Croup-like Inspiration of Infants, with Illustrations of the Principles of the Pathology of Nerves, and of the Functions and Diseases of

the Larynx and its Principal Branches. By John Ley, M.D., Lect. on Mid. at St. Barth's Hosp. &c. 4th edition. London: John Churchill, Princes-street, 1836, 8vo., pp. 484.

The Anatomy of Melancholy, what it is, with all the Kinds, Causes, Symptoms, Prognostics, and several Cures of it. In three partitions. With their several Sections, Members, and Subsections, Philosophically, Medicinally, Historically, opened and cut up. By Democritus Junior. To which is prefixed a satyricall preface, condescending to the following discourse. 16th edition. Printed from the authorized copy of 1651, with the author's last corrections, additions, &c. &c. London: B. Chidley, 1836. 8vo. pp. 744.

The Naturalist's Library,
Sheep, &c. With colour
don: Highbly.

CORRESPONDENT.

The letter respecting the meeting at *St. Thomas's Hospital* reached us, and it was designed to be inserted, but on receiving a copy of the following resolution, in which the students at that institution express their strong opposition to the proceedings of the Apothecaries' Company, we saw reason to doubt the correctness of some of our correspondent's inferences. The resolution says,—"That this meeting regrets there does not exist a second examination for medical pupils, and that second examination a public one, to which any rejected candidate might appeal, as this would at once silence the murmurs of incompetency, and destroy the possibility of private injustice. That this meeting also strongly disapproves of the principle of self-election and irresponsibility in medical corporations.

"W. WEGG,

CHARLES EDWARD BLAIR, Sec."

Mr. Samuel.—It is not on Friday week, but on Tuesday next. There will be no speechifying on the occasion.

Anti-Humbly should favour us with his name and address confidentially.

Q. in the Corner may be assured that the College of Surgeons will not discharge its duty to the profession.

The letters of Dr. McCarthy, Mr. Eekley Pattison, Mr. J. C., and Medicine Dumfriess, have come to hand.

Such a mass of communications have reached us relative to the proceedings of the late inquest at Limington, that we are obliged to postpone for a week a further account of them.

The communications of Dr. Bow, Mr. Fisher, Dr. Kelso, R. E. L., &c., have been received.

ERRATUM.—Page 867 of the present No., line 6 from bottom, read *St. Petersburg*.

THE LANCET.

Vol. I.]

LECTURES ON DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and
Professor, and Lecturer on the Principles and
Practice of Medicine, in the Faculté de Médecine
of Paris.

LECTURE XIV.

RAMOLLISSEMENT OF THE NERVOUS CENTRES.

GENTLEMEN,—The lesion now well known under the name of "ramollissement," or softening of the nervous pulp, is characterized by the following

Anatomical Appearances.

The first and essential character is a diminution of the normal consistence, in which the nervous pulp seems to have taken a tendency to pass from its solid to a liquid state. The lesion, thus characterized, may, as you can readily conceive, present itself under a great variety of degrees. Sometimes the normal consistence of the nervous pulp is very slightly diminished, and the latter, though softened, retains its accustomed form and organization; the change is appreciable to the touch, but not to the eye. Thus if the lesion occupy the corpora striata, we can still observe the medullary bands in the interior of this portion of the brain, and the several anatomical peculiarities of its normal state. If the optic thalami be the parts affected, we can recognise its several parts, and, in fact, although softened, they exist separately, and are not confounded together. In a second degree of ramollissement, the consistence of the nervous substance is still more considerably diminished, and the softening is appreciable on simple inspection of the part. In a third

degree, texture, hitherto unchanged, is more or less modified. The cerebral substance is broken down into a soft homogeneous mass, of the consistence of "stir-about." If water be poured upon the brain in this state, the nervous matter is easily separated from the membrane which envelops it, and forms numerous flocci that are suspended in the fluid. These fine, minutely-divided portions of the nervous pulp give a lactescent colour to the water, which might be mistaken for the effect of an admixture of pus; but it is not pus. The floating whitish flocci do not depend on the presence of purulent matter, because exactly the same appearance is produced when a portion of putrefied brain is deluged in water. Lastly, the nervous pulp may disappear altogether; we find no trace of medullary substance, which has become altogether liquid, without the slightest consistence or texture. Of the cerebro-spinal substance, nothing remains but the vasculo-cellular web, which in a normal state is masked by the nervous matter, and of which it seems to be the primary rudiment. In a few cases the softening is carried to such a degree as to produce an actual solution of continuity: not only the nervous pulp has disappeared, but the cellular tissue just alluded to. M. Rullier has described a remarkable case of this latter kind, where the cervical portion of the spinal marrow was completely separated from the dorsal, nothing being left but a few fibrous filaments suspended in a fluid. M. VELPEAU records a case, still more remarkable, in the *Archives Générales*, t. 7, p. 52. Here the medulla oblongata was separated from the pons in the most perfect manner; not a trace of fibre existed between them, and even the membranes themselves had disappeared.

Thus you see how the lesion whose history we now study, may present itself with various degrees of intensity, from a slight modification of consistence, where the original form and texture of the nervous substance remain unaltered, to that extreme degree in which it has returned to its primitive and liquid state—to the homogeneous fluid that fills the membranes in the earlier period of fetal existence. In some cases

the change from its normal consistence is so perfect, that it would seem as if the different acts of nutrition had retrograded, and led back the nervous substance by insensible modifications to its primitive condition of a liquid. Ramollissement of the nervous centres may present itself with the simple character of loss of consistence, unaccompanied by any other lesion; but at the same time that the nervous pulp is softened, it may be attended by various modifications of colour, which we can arrange under three distinct heads.

In the *first* place, ramollissement may exist with a normal coloration of the nervous substance. The softened portion is neither more pale nor more injected than is natural.

In the *second* variety, we find the nervous pulp deprived of its normal colour, and of a dull white tint, and, as it were, affected with anemia. The colour sometimes resembles that of milk, or is more bright and resplendent; this is particularly the case when the lesion occupies the gray substance of the brain or spinal marrow. It is a circumstance which you should take particular care to remember, that softening may present itself, not with injection and other characters of inflammation, but with a perfect decoloration. On the other hand, if the ramollissement be confined to the medullary substance, we more frequently find it of a normal colour.

In the *third* variety, ramollissement is attended with an increased injection of blood, with an exaggeration of normal vascularity, giving rise to various shades and tints, from a slight rose to deep red or mahogany brown.

Ramollissement is also from time to time accompanied with certain lesions which we shall briefly enumerate. Thus we sometimes find the softened nervous pulp more or less infiltrated with serosity. In other cases ramollissement coexists with sanguineous effusions, which are sometimes very considerable, in proportion to the softened mass, at other times insignificant and disseminated through the altered pulp. The lesion however is by no means a necessary, though it may be a frequent consequence of ramollissement; it depends on an irritation of the nervous substance, or sometimes on a cause purely mechanical. The softened mass is no longer able to support the finer vessels; these latter become over-distended, their parietes give way, and the blood is effused in greater or less quantity, according to the importance of the injured vessel.

Finally, we may meet with purulent matter, either infiltrated, or collected into an abscess, in the centre of the softened nervous substance.

Thus you see a variety of cases presenting to our view, not only different degrees of the same lesion, but an assemblage of lesions differing widely from one another in essen-

tial characters. These necessarily constitute several varieties of the disease, and we must consent to refer ramollissement with injection, and ramollissement with decoloration, to one and the same state. Undoubtedly the conditions are different, and so are the causes which produce them. Observe, there are cases, where not a single organ has been found in a state of softening, but where all the organs and tissues of the body have been more or less ramollified, where all the organs present a diminution in their normal consistence. Are we to attribute this state to an universal inflammation? Are we to say here that the whole body is but one phlegmon? Absurd. Every rational physician, instead of pushing the doctrine of inflammation to this ridiculous extent, will frankly avow that there are lesions of whose nature and cause we are still completely ignorant. I call to mind, on the instant, an example which may serve as an illustration of what we have just advanced. A student of the Polytechnic School was seized with symptoms of the disease which nosologists are agreed in calling "typhus suraigue" (the worst form of typhus fever). The disease was very rapid in its course, and after death we found all the organs, particularly those abounding in parenchymatous tissue, reduced to a state of perfect bouillie, so soft that the least touch crushed them in pieces: the different muscles were softened in the same way. The muscular tissue was crushed down on pressure, like a portion of brain. Are we to suppose that all the muscles, all the viscera of the head, chest, and abdomen, in the present case were affected with acute inflammation? Are we gratuitously to adopt this latter idea, in the case now alluded to in order to please those who see nothing in ramollissement but an effect of inflammation?

Having thus endeavoured to lay before you a concise history of the anatomical characters that distinguish ramollissement from all other lesions of the nervous centres, we shall now point out the different

Seats which this Lesion may occupy.

Ramollissement may have its seat in any one point of the nervous centres, either in that portion which is contained within the cavity of the cranium, or in the prolongation, without the skull, which is denominated the spinal marrow. This ramollissement may be partial or general; the former lesion is much the more common; indeed we do not yet possess a case of general softening of the cerebro-spinal axis, although the totality of the parts constituting the brain has been found softened in a greater or less degree; however, this latter lesion is rare, and presents itself only in a few exceptional cases; partial ramollissement may, as we have just said, occur either

in the brain, or in the spinal marrow; here is the first great distinction according to the seat of the lesion. In the cranium we may find any part affected; ramollissement attacks without distinction the convolutions, the deeper seated parts of the hemispheres, the mesencephale, or the cerebellum; and we may lay it down as a general rule, that the parts in which it is most frequently observed are the same where hemorrhage also is most common; for example, in the corpora striata, the optic thalami, and the neighbourhood of those two ganglionic bodies. Let us first examine ramollissement when seated

In the Hemispheres of the Brain.

Here the lesion may be confined to a small point of the convolutions, attacking either the superficial layer of the cerebral substance, or having its seat in the deeper parts, immediately beneath the convolutions; either of the two layers now mentioned may be engaged in the disease, independently of one another. When the superficial layer alone is softened, it requires some attention not to overlook the existence of the lesion, which may easily escape your notice; in these cases the cortical substance is raised up with the pia mater, which cannot be detached from it; it is generally more injected than natural, but sometimes the softened nervous pulp adherent to the membranes is very pale, and colourless.

Ramollissement may, on the other hand, respect the superficial substance, and attack the nervous mass situate immediately beneath the convolutions; or we may find it still deeper, in the centrum ovale, or in the nervous substance which forms the roof of the lateral ventricles; this latter mass may be softened in totality, or the ramollissement may occupy merely a few isolated points of small extent, and it is remarkable that this latter lesion, though apparently so insignificant, may sometimes give rise to symptoms just as grave as when a whole lobe is softened.

In some cases we find the softening confined to the optic thalami, the corpora striata, or one or both of the medullary protuberances contained in the anterior horns of the lateral ventricles (*cornua anteriora*); the optic thalami are sometimes softened on the surface only; the white medullary layer by which they are enveloped, no longer exists, or is reduced to a kind of fluid pulp, and the gray substance beneath is exposed. At other times the ramollissement is more particularly in the interior of the gray substance; the same remark is applicable to ramollissement of the striated bodies and the horns of Animon.

Again, we find, occasionally, softening of other parts of the nervous centres; thus, it is not uncommon for ramollissement to oc-

cupy the nervous pulp which forms the parietes of the lateral ventricles; in many cases we have found a layer of nervous matter, softened, and quite diffuent, spread all over these parietes, and at the same time a quantity of serous fluid shed into the ventricular cavities.

The central white parts of the brain (the corpus callosum, septum lucidum, and fornix) are also the seat of ramollissement, and this not unfrequently. Here, as in the other parts we have enumerated, the softening may be either general or partial; in some the ramollissement is so extensive, and carried to such a degree, that all these central parts are reduced to a fluid state, and nothing remains in their place but a substance of a homogeneous nature, little more consistent than jelly. The septum lucidum and fornix are more frequently found softened and reduced to this "bouillie," than the white mass constituting the corpus callosum; this latter body often preserves its normal consistency when the fornix is reduced to a mere pulp, and breaks down under the slightest touch, and we may remark that the pillars of the fornix, especially the anterior, are commonly less softened than its body.

Ramollissement of the septum lucidum and fornix coincides in a very great number of cases with an effusion of serous fluid into the cavity of the lateral ventricles; the nervous substance is then sometimes reduced to such a degree of diffidence that we find nothing but a number of flocci, floating here and there in the serum which distends the ventricles.

Behind the parts we have just mentioned there are others that occasionally are the seat of ramollissement, but not so frequently as the brain, strictly so called. Thus we have examples on record where the mesencephale (pons varolii), the peduncles of the cerebrum and cerebellum, and, lastly, the cerebellum itself, have been seen more or less softened.

The Cerebellum and Spinal Marrow.

In some cases the whole mass of the cerebellum has been found in a softened state, in others the disease is less extensive, and we observe only a partial ramollissement, occupying one or more points of its substance.

Finally, ramollissement may exist in that part of the cerebro spinal axis which is placed out of the cranium; several cases of softening of the spinal marrow have been described: sometimes in its whole extent; at others, and much more frequently, in a limited portion. The two substances which compose the spinal marrow may be softened, either together or separately. Thus, for example, it may attack the gray substance alone, which occupies the interior of the chord, reduce it to a liquid pulp, and hollow

out the artificial canals of which we have spoken when treating of atrophy of the nervous centres.

Instead of being partial, a lesion which is by far the most common, ramollissement may occupy the whole of the cerebro-spinal axis. The whole brain and spinal marrow are simultaneously reduced to a liquid pulp, in which all trace of organization is lost. M. BILLARD has described ten cases of this kind, where softening of the whole brain coincided with a similar state of the spinal marrow. Finally, in the totality of the cerebro-spinal axis we may have only a single point softened, or the lesion may affect several distinct points at the same time; it is thus single or multiple. In the hemispheres it is often double, and it may be formed, either at the same time or gradually, in the brain, properly so called, and in the other parts of the nervous centres.

What are the Causes of Ramollissement of the spinal marrow and brain? To complete the history of any disease we must endeavour to ascend to the causes which produce it, with the same care that we investigate its symptoms or point out its treatment: but the causes which give rise to softening of the cerebro-spinal axis are very little known. Indeed, the only one whose existence we can consider as actually demonstrated, is external violence, and in these cases the ramollissement is an immediate effect of irritation or inflammation. In cases where we can find no trace of irritation, where the nervous pulp, far from being injected, is, on the contrary, decoloured, and where the whole lesion consists in a simple diminution of cohesion, in these cases we must acknowledge that the present state of the science does not permit us to explain the cause of ramollissement.

Softening of the nervous centres exists at all

Periods of Life.

It has been observed immediately after birth, even before birth, as a disease of the fetus *in utero*. Cases of ramollissement in the adult are not rare; in old persons they are frequent, and hence we may conclude that this lesion attacks individuals of all ages, from infancy to extreme old age, from the child of one month to the decrepid invalid of 80 or 90.

Is ramollissement the same at all ages, does it present itself more frequently at one period than another? We have just shown that the existence of ramollissement at all ages is a fact placed beyond doubt by the observations of LALLEMAND, ROSTAN, BILLARD, and ourselves. However, we cannot but admit that it is a lesion more frequently found at an advanced age than at any other period of life; but if you ask on what data we establish this proposition, if you desire to know in what proportion the different

ages are attacked, we cannot give you a satisfactory answer. In examining the various works which have been published on ramollissement of the nervous centres, you will find a great majority of cases occurring in old persons, but do not conclude from this that the disease is almost exclusively confined to old age. The cases of ramollissement hitherto published concern principally individuals advanced in life, because their authors were attached to, or studied in, the hospitals appropriated to the aged and infirm. Thus, in M. ROSTAN's work on ramollissement, you will certainly find the majority of cases reported belonging to old people, because M. ROSTAN was attached at that time to the *Salpêtrière*, and all his cases were taken from that hospital. Indeed, we have no extensive collection of cases observed in any other establishment. The work of M. LALLEMAND is an excellent one, but his observations and deductions are chiefly founded upon cases reported by various authors which he has assembled together. It is probable, then, that if the physicians of other hospitals were to make this lesion the subject of special research, we should soon have as many cases recorded of softening in the adult and the child, as we now possess of cases in the aged. Thus, while attached to the hospital of *La Charité* (which receives patients of all ages indiscriminately), I observed several cases of softening of the nervous centres in individuals from seventeen to twenty years of age. At the hospital *Des Enfants Malades* the disease is frequently seen, though we have no statistical report on which we can determine the proportion of cases. Finally, as we have already remarked, M. BILLARD shows that ramollissement may exist to a very great extent within the first few days after birth. Let us now turn to a consideration of the

Symptoms which accompany Ramollissement of the Nervous Centres.

Here, indeed, our task is a difficult one. To convert particular signs into a general description, to follow up the connection of cause and effect through a series of accidents, succeeding each other at every instant, replacing one another, or connected without any apparent order and regularity: to separate the various modifications of function which depend upon the complication of ramollissement, from the phenomena really produced by the lesion itself; to seize the traits of resemblance scattered through a multitude of different points, to throw them together, and form of the whole a faithful resemblance. These are points which, however difficult, we must now endeavour to attain.

The symptoms of ramollissement present themselves with a certain degree of difference, as the lesion may happen to occur

different portions of the cerebro-spinal axis; and hence, according to the practice we have hitherto followed in the present course, we shall follow the disease as it exists in the cerebral hemispheres, in the central parts of the cerebrum, in the cerebellum, and in the spinal marrow. And first, for the brain; how are the great functions of the brain modified by ramollissement? What

Lesions of Intelligence

do we observe in this disease? The state of the intellectual faculties is far from being the same in all cases of ramollissement of the brain; in the first place, we observe a certain number of examples, and they are by no means rare, in which the intelligence does not suffer any trouble whatever: the reason, judgment, memory, imagination, &c., and, in a word, all the faculties of the mind, are in a perfect state of integrity. In a second series of cases the intelligence is suddenly lost at the moment of invasion of the disease; this takes place when ramollissement commences by a sudden loss of consciousness, or by coma, as in apoplexy. At the termination of a few days the intelligence is restored, either perfectly, which is rare, or imperfectly, the patient remaining more or less dull up to the moment of death.

In a third series of cases the intelligence is modified from the beginning to the end of the disease, but the mental faculties are never completely lost, as in the former cases; here the intelligence is obtuse, dull; the various acts of the mind are performed with slowness and difficulty; the patient has that oppressed and stupid air which often marks the presence of typhus fever; when spoken to, they answer slowly and uncertainly; the memory is weakened, and their ideas are somewhat unconnected, or they fall into a state of constant sleepiness, which is sometimes one of the most striking phenomena of the disease.

Finally, in a fourth variety, the intelligence is so far disordered and troubled that delirium results. This is particularly observed when ramollissement commences as an acute malady, or is accompanied by any of the symptoms that characterize encephalitis, or acute inflammation of the cerebral meninges. This delirium may exist in a constant manner, or only manifest itself at intervals, the intelligence remaining quite sound during the intervening periods. In some cases it makes its appearance at the very commencement of the malady. In other cases it comes on at a later period, and occasionally alternates either with a state of reason or with coma. Finally, it may exist in a form sufficient to constitute a true mental alienation.

The different conditions of intelligence now pointed out may exist by turns in the same individual, and we have seen cases where the mental faculty has suddenly re-

turned in a perfect state a few hours before death, although it had been previously troubled, or even lost, during the whole course of the disease. Thus you see by what a variety of lesions of intelligence ramollissement of the brain is accompanied,—lesions so different and so uncertain that they cannot in any way serve to aid us in our diagnosis of the disease. Perhaps they may depend on the seat of the lesion; perhaps they are modified by its intensity, or by individual dispositions of constitution; perhaps various troubles of intelligence may be caused by different degrees of congestion which coexist with ramollissement, or can only be explained by a special disposition of the nervous centres, which, though suffering under one and the same organic lesion, yet are capable of manifesting the effects of this lesion by functional modifications of the most various kinds. However, as we have already said, it is not rare to find ramollissement passing through all its periods without having once given rise to any trouble of the mental faculties. We have frequently seen examples of this kind, but, on the other hand, it is more common to find the intelligence more or less obtuse.

Lesions of Motility.

The movement is injured in a much more frequent and constant manner than the intelligence. Exceptions do, indeed, exist where we find no lesion of motility; but these cases are very rare, and we may lay it down as a general principle that modification of motility is the lesion which characterizes most specially, softening of the brain. What is this modification? In what does it consist? How does it manifest itself? Nothing would be more convenient for the practitioner, nothing would contribute in a greater degree to render medicine an easy science, and to smooth down the difficulties which now beset us, than the discovery of an invariable and constant connection between certain symptoms and certain lesions. Thus, some authors contend that ramollissement always gives rise to muscular contractions; others contend that contraction ends in paralysis. But, unfortunately, nature does not always follow the same route; if we have contraction of the muscles in many cases of softening of the brain, there are certainly a few in which this phenomenon never existed.

The motility, then, like the intelligence, may undergo various modifications as a result of ramollissement of the cerebral hemispheres. The lesion may be gradual or sudden. First for those cases in which loss of motion comes on in a slow and gradual manner. Some patients are seized with a weakness of the limbs on the side of the body opposite the lesion; the hand, for example, has lost its accustomed force, and cannot grasp an object so firmly as before.

The whole arm seems heavy, or the leg drags along in walking. This comencement of paralysis gradually augments, until at length the patient is completely deprived of the power of motion on one side of the body. We have frequently had opportunities of witnessing this ourselves, and in cases of this kind we may distinguish this weakness of limbs produced by ramollissement of the cerebral substance, from the loss of motion which supervenes in consequence of hemorrhage, for in effusion of blood into the substance of the brain, the paralysis is generally brusque, sudden, instantaneously produced, whereas in ramollissement we observe quite an opposite fact; we first have simple weakness, and it may take a series of years before this terminates in perfect loss of motion.

In other cases the paralysis appears suddenly, and does not pass through the different degrees we have mentioned; the patient suddenly loses the power of moving his limbs, which are completely paralyzed in a few moments after the commencement of the attack. Here ramollissement bears the greatest resemblance to cerebral hemorrhage, and it is absolutely impossible to distinguish the two diseases at first from one another. In the state just mentioned, several cases present themselves; thus, sudden paralysis may seize the patient, without being accompanied by any other morbid phenomenon: the patient is simply deprived of the power of motion in one or more limbs, but no other function is deranged or modified. In other cases this simple paralysis is replaced by convulsive movements, which persist for a greater or less period of time, and then terminate in paralysis. The convulsions generally occupy the side of the body opposite the softened hemisphere; they sometimes mark the commencement of the disease, then cease, and give place to contraction or paralysis. In other cases they manifest themselves at a later period, alternating with paralysis. The convulsions, instead of being confined to one side of the body, may be general; both sides are equally affected, and in these cases you will often find the cause explained by a double lesion of the brain, both hemispheres being softened at the same time. Finally, instead of occupying the side of the body opposite to the injured hemisphere, the convulsions may affect the limbs on the same side as the lesion in the brain. It is not now the place to enter into the considerations to which this latter fact is calculated to give rise; we can only observe, that in all cases where these convulsions exist, or where convulsion, alternating with paralysis, presents itself, we may have reason for thinking that another disease than simple hemorrhage exists; we may be justified in attributing the lesion of motility to ramollissement of the cerebral hemispheres.

CLINICAL LECTURES

SURGICAL CASES

DELIVERED IN 1836, AT THE

JERVIS-STREET HOSPITAL, DUBLIN,

BY

WILLIAM WALLACE, M.D., M.R.I.A.,

Surgeon to the Hospital, and to the Infirmary for Diseases of the Skin, including Venereal Diseases, and the consequent Diseases of the Urinary and Genital Organs, &c. &c.

INFLUENCE OF THE HYDRIODATE OF POTASH IN MALIGNANT FUNGUS AND CANCEROUS DISEASES.

I beg your attention this morning to the case of the servant man Keogh, who lately died in Ward No. 6. It is, in many points of view, full of interest. It affords a good example of one of the most malignant diseases to which we are subject, of the insidious manner in which such diseases may commence, of the difficulty of distinguishing them at their origin, and of the sad consequences that may result when their nature is misunderstood; but above all, it seems to demonstrate, as far as one case can, that a remedy, the hydriodate of potash, with which we have been only of late years made acquainted, is capable of exercising on such diseases a most remarkable influence. The general power of this medicine is, in my opinion, as yet underrated, and, perhaps, because its mode of administration is not understood. I shall have many opportunities of demonstrating this to you as soon as I enter on my clinical lectures on the venereal disease, when I shall give you the result of nearly three years' clinical investigation on the power of this medicine in syphilis. Whether the remarkable change which we witnessed in the case of Keogh was owing to the influence of the hydriodate of potash, I allow, admits of a doubt. A single case is quite insufficient to establish a fact of this kind, but it is amply sufficient to induce us to investigate the subject further; and if it should turn out to be a fact, that this remedial agent possesses the power which I have reason to believe it does possess, there will open to our view a vast field of hope, that the period is not distant when we shall be able to control by medicine one of the most horrible, and hitherto most irremediable diseases, which in these countries come within the observation of the surgeon.

Case of Keogh.

You can scarcely have forgotten the state of this poor man when he fell under my care. Although very many fungous and malignant diseases have recurred to my observation, I

shall never forget it. I have never seen one more remarkable, whether we consider the peculiarity or the malignancy of its aspect. Here is a drawing of the disease, well executed, and by an admirable artist, Mr. O'Neill, yet it affords but a very inadequate idea of the disease. You may form from it, however, a correct notion of the extent and

figure of the diseased mass, or picture to yourselves the head of an immense cauliflower seated in the right groin, and a smaller one on the side of the penis, this organ, as well as the scrotum, being proportionably enlarged, and you will have an ideal representation of the seat, extent, and form of the diseased parts.

The tumour in the groin was, as the drawing represents, of a rounded or oval form, fully seven inches long and five inches broad. It extended, as you observe, from within two inches of the spine of the ilium to the front of the pubis, and from three inches above to two inches below Poupart's ligament. Its surface, which was in general extremely irregular, or full of knobs and depressions, presented about its middle part a deeper excavation, which, as well as the smaller depressions or cavities, always contained a quantity of a thin, clear, yellowish fluid. This fungus, for I may well call it by that name, rose in many parts fully three inches higher than the surrounding skin. The general appearance of its surface was by no means unlike that of the growth which often protrudes from a suppurating testicle. Its colour was whitish, broken up by brownish red patches, by patches of a

paler red colour, and by spots of a brighter red. Some of the brown patches felt soft and elastic. The redder were comparatively firmer, many of the whiter patches had a yellow tinge, particularly in the middle of the tumour, and these seemed to have less vitality than the other parts. The discharge was very copious, and was partly serous or ichorous, and partly puriform. These discharges seemed to come from distinct parts. The former, or the thick puriform discharge from the surface of the fungus, and the latter, or ichorous, from the edge of the skin, and from the subjacent subcutaneous tissue. In fact, the one seemed to exist, to a certain extent, distinct from the other. The border of the tumour overhung considerably the integuments, and, hence, the edge of skin, which surrounded the neck of the mass, could not be distinctly seen, except at the side next the pubis. The gra-

mulations in the inside of the edge, when this could be seen, had rather a healthy appearance, and seemed to secrete puriform matter. The skin, for several inches at the outer or right side of the tumour, was of a deep purplish red colour, not uniformly so, but in streaks. In all other parts, the surrounding skin presented a healthy appearance, excepting between the tumour on one side, and the penis and scrotum on the other, and there it was livid and very much thickened.

The fungus, or tumour on the penis, was seated on its right side and under part, and was not less than three inches in diameter. It resembled in its form and colour, in a very striking manner, the larger tumour in the groin. It was, however, of a firmer consistence and paler colour. It was rounded, and its circumference overhung the edge of the skin. Its surface was irregular, presenting numerous depressions of a small size and a larger hollow in its centre. All the depressions were filled with a clear ichor.

There were, also, as you may remember, on the common integuments of the penis, two other diseased spots, of a smaller size, one on the right side, of the magnitude of a large pea, of a whitish pulpy appearance, considerably elevated, and the skin mounting at its side, so as to reach the level of its surface. The second was on the left side of the penis, and of the diameter of a farthing. One portion of its surface was sloughy, or pulpy, and another was covered by apparently healthy granulations. This diseased patch was continuous, at one side, with the larger fungus on the penis, and in every other part it was surrounded by skin which had a healthy colour, but was raised into a kind of welt, which thinned down as it approached the immediate edge of the sore.

The integuments of both penis and scrotum were greatly thickened, and of a crimson colour, with a tinge of lividity. The scrotum was elongated and lax, and was kept constantly bathed with the discharge which flowed down from the fungous masses. The spermatic cord at the right or diseased side was as thick as a finger, but the same part on the left, as well as the lymphatic glands of the corresponding groin, were free from enlargement. Besides the discharge which was effused from the surfaces of the tumour, and from their circumference, there was a copious puriform discharge from an opening or slit in the front of the scrotum, which led into the cellular tissue, as well as from the orifice of the swelled prepuce.

He was very pale and much emaciated. His pulse was upwards of 100, and very weak. He had well-marked paroxysms of hectic. A rigor commenced each night about nine o'clock, at which time he was in the habit of rising to get his bed made, and this was followed by a perspiration, pretty much confined to his head and

breast, more copious on some nights than others. His tongue was rather clean, his bowels had primary secretions regular; no thirst, and some appetite; no cough, and respiration good. There was scarcely any sensibility in the diseased parts, or in the surrounding skin, when handled, yet he was always moaning, as if he was in much pain. He described the pain as a dead heavy uneasiness, with an occasional darting sensation through the parts, which distressed him

from the time he entered the hospital about ten days, I believe, before he fell under my care, and I have been informed that when he was admitted the tumours were not more than half the size which they were when I first saw him; that the skin surrounding the one in the groin was of a livid colour, very tender, and presented numerous small varicose veins distributed through its structure; that the surface of the tumour was insensible and tubercular, or very much of the form of a bunch of hydatids. I have been also informed, that it presented (probably in consequence of the manner in which the edge of the skin was hidden by the overlapping fungus) such an appearance as to lead to the supposition that the disease was seated in the integuments rather than in the subcutaneous parts, and that it did not resemble either fungus hematodes or cancer, but was, in appearance, like the fungus which often grows from a testicle which has undergone chronic inflammation and suppuration.

It is, in general, very difficult to obtain a satisfactory account of the origin and progress of a disease which has been some time in existence; but as all the circumstances of this case were such as to make me very desirous to ascertain with accuracy its history, I took considerable trouble on the subject. I interrogated the patient and his wife separately, and made some inquiries from persons who had seen him in an early stage of the disease. From these sources of information it appeared that up to about sixteen months ago, at which time he was thirty years of age, he had a perfectly healthy constitution, that he never had contracted any venereal disease, except one about five years ago, and that was not followed by any secondary symptoms, that since then he had been married, that his habits had been very regular, that he never gave any disease to his wife, although he had intercourse with her long after the present disease commenced. I further learned, that about sixteen months ago a small elevated sore, or livid spongy wart, was observed on the right side of the inner surface of the prepuce, near the corona glans, which was soon followed by another, of a similar kind, and seated on a part very near to the former. They united in a short time. They were not painful, nor did he

give any attention to them, and until about seven months ago they made little progress. At this time he was thrown from a horse, dragged for some way on the ground with his foot in the stirrup, was rendered insensible, and, on the whole, experienced at the time a great shock. Soon after this his attention was attracted to his right groin, where he felt a small firm kernel. This gradually increased to the size of a pigeon's egg. He now applied at an hospital, where he got black wash and pills, which gripped him very much, and made him much worse. He next consulted an hospital surgeon, who saw him at his own house, from whom he got pills, which he believes were mercurial, but they did not make his mouth sore. Not finding himself improved, he went into an hospital. Even at this time he could denude the glans penis, and the tumour was neither very large nor discoloured. He was now, unfortunately, put under a mercurial course, which excited much inflammation, and phymosis in consequence ensued. The tumour in his groin increased, and became red. An ulcer now formed on the outside of the inflamed prepuce, opposite to where the wart to which I have alluded was placed, and through this ulcer a fungous mass quickly protruded. The tumour in the groin soon after increased to the size of a goose-egg, and was still remarkably hard, but after a time it became irregularly soft, and of a livid or crimson colour. At this period, finding himself much worse, he solicited his discharge from the hospital, and, soon after, the skin covering the tumour in his groin gave way, and a fungus protruded. He now placed himself under a country peasant, who gave him "herbs," and he remained under this treatment until he was admitted into this hospital.

When I first saw this patient, I asked, "What has been done for him since he came into our hospital?" "The parts have been covered with a common poultice, and creosote has been administered internally," was the reply. That no advantage had resulted was evident, for the disease had doubled its dimensions since his admission; his hectic symptoms had rather increased; he seemed miserable in his feelings; his nights were restless, and his pain was great. I contented myself, on my first visit, with directing the poultice to be omitted, and fine linen to be put on the part wet with a weak solution of the chlorate of lime. I also directed that there should be given an antispasmodic draught, and, during the day, my favourite cordial mixture, carbonate of ammonia and compound tincture of cardamom, with a minute quantity of tincture of opium, made grateful with sirup of orange-peel, and some aromatic distilled water.

These changes in his treatment seemed to add to his comfort, and greatly diminished

the stench which was about him. He still, however, looked wretched, and appeared in great misery. "Can anything now be done?" I asked myself. Now, gentlemen, this was precisely one of those cases in which we may be justified in trying any remedy which affords a ray of hope; a kind of case which demands, in fact, from every man anxious to extend the boundaries of his art, a trial, within proper limits, of empirical treatment; that is, of remedies which we know to possess the power of influencing the system to such a degree as to afford a possibility that they may by their action influence the disease. We are often, indubitably, obliged to act in this manner. How frequently are mercury and arsenic given upon no better foundation! I had, as you know, been trying for a long period, and in various cases, with remarkable success, the hydriodate of potash. Come, said I, let us try it in this case. I ordered it, but with scarcely a ray of hope that it would in any way control or influence the morbid actions going forward. It was given to him in the dose in which I commonly administer this medicine; that is, seven grains three times a day, in an aqueous solution. He commenced on the 9th of October; on the 12th I observed, on going round the wards, a decided alteration in the style of his countenance. He looked, comparatively speaking, tranquil. He told me he had had a better night than any since he had come into the hospital, and that the pain in the parts was much diminished. Could these changes be owing to the hydriodate of potash? I reflected with myself. I could not, I confess, feel that they were. This medicine was, however, continued. I saw him daily, sometimes looking at the tumour, and sometimes not, but I did not notice any remarkable change further than that which I have just mentioned, that is, in the state of his pain, until the 18th, or nine days after he had commenced the hydriodate of potash, when he complained very much of soreness of his throat. On the 20th he complained still more. I examined his throat, but could not observe anything to be the matter. Presuming that it was a state of throat analogous to that which not unfrequently occurs from the employment of the hydriodate of potash, I directed him to discontinue this medicine, and to take a mixture containing the sulphate of quinine. On the same day I examined the state of the tumours, and they appeared to me to be a little smaller. Of this, however, I had not more than a suspicion, for the decrease was, if any, not remarkable. There was, however, an evident change in the appearance of their surfaces; they had become more dead and crumbly, and particles of them could be removed by the forceps. His urine on this day was loaded with the hydriodate of potash.

On the 24th of the month, or fourteen days after he had commenced the hydriodate of potash, the alteration in the state of the tumour, as you may remember, excited the greatest surprise. It was evidently not one-half its former magnitude, and the surface was rapidly crumbling away. There was no pain in the part, no surrounding inflammation; the dull heavy sensation and the shooting pains had entirely ceased; he appeared quite tranquil; his nights were spent comfortably; his appetite continued, and, on the whole, there was so remarkable a change, that I was nearly vain enough to suppose it possible he might recover. I now directed the hydriodate of potash, a trace of which was still visible in his urine, to be again given, but in half doses only; and to prevent the return of that state of throat of which he complained so much, and which had, in a few hours almost, been controlled by the quinine, I directed that he should continue his quinine mixture, taking it before, and the hydriodate of potash after his meals.

Under this treatment his throat continued easy, the decrease in the size of the fungi progressed, their middle portion crumbled away more rapidly than the circumference, and the diseased mass in the groin now assumed strikingly the appearance of an ordinary carcinomatous sore. The comparatively happy and tranquil state which I have already remarked, persisted, and his appetite remained sufficiently good. But, notwithstanding these pleasing circumstances, his weakness increased, his pulse became more debilitated and thready. In short, the disease seemed to be going off, and his strength to be, in the same proportion, declining.

On the 10th of November, at which time he was still continuing his medicine, the diseased fungous mass had totally disappeared from several parts, and at these parts the surface had acquired the aspect of a phagedenic or sloughy sore, yet there was scarcely a blush of surrounding inflammation, and no pain.

The hydriodate of potash was now omitted, the sulphate of quinine was continued, and the diseased surfaces were covered with hot dressings of oleum and turpentine.

On the 22nd of November there was not a trace of the fungous masses; the penis seemed as if it had been amputated exactly between the fungus and the comparatively sound part. It, as well as the scrotum, was no longer either swelled or red. The size and inflammation of these parts had declined with the decrease of the tumour. The fungous mass in the groin had also disappeared, and a deep and dark excavation, of the size of a plate, occupied its place.

He was now sinking rapidly, yet he still presented an appearance of remarkable contentment, and exhibited an extremely

tranquil countenance; his pulse sank to a thread, his voice became so weak and scarcely that he could scarcely be heard; he did not, however, complain of his throat. In four days after, that is, on the morning of the 30th of November, he died, without a groan or complaint; the progress of his dissolution was so tranquil, that he seemed to have gradually passed from sleep into eternity.

Autopsia.

I examined the body six hours after death and made at the time a note of the dissection, which I shall read to you:—

“Extreme emaciation; no oedema of the lower limbs; the transparency and thinness of the skin covering the arms and thorax, allows a tint of colour produced by the subjacent muscles to be observed, which gives very much the appearance, on the surface, of incipient putrefaction. The lower limbs are slightly stiff, but the muscles of the upper part of the body are quite free from rigidity.

“The diseased surface, which had the groin for its centre, is fully seven inches long, and six inches broad. It is covered by a thick stratum of pulpy brown matter, which is easily scraped off with the back of a knife. In thus clearing away the pulp, a portion of the anterior wall of the femoral vein has been removed. The internal surface of this vein, extending up and down for an inch from this part, is of a dark-brown colour, like the pulpy mass which covered the diseased surface, and is softened in its texture. At this part, and for some inches above and below, the vein is imperfectly filled with a coagulum, devoid of colouring matter, as far as the vein is discoloured; but above and below this, it presents the usual red appearance of such coagula. The femoral artery seems sound, yet the parts covering it are scarcely less diseased or softened than those which covered the vein. The cellular texture on the lateral and posterior aspects of these vessels, has, when divided with a knife, somewhat of a cartilaginous appearance. The femoral nerve does not appear diseased. The aponeurotic expansion of the external oblique muscle, as well as the fascia lata, are exposed, upon the removal of some soft brown matter which covered them, and their structure seems softened. This extensive diseased surface does not appear to have any base, or, in other words, the more subjacent parts do not appear diseased. The extremity of the penis has been removed, and the end of it is covered with the same soft or pulpy matter as was observed in the groin. When this softened matter is rubbed off, the orifice of the urethra, the extremities of the corpora spongiosa and corpus cavernosum, appear softened at their ends, but without the slightest aspect of thickening, or as if there had

been any inflammatory action. The spermatic cord is quite insulated from the external ring to the testis, and its covering feels thick and firm. Its component vessels and nerves seem sound; both the testes also seem sound, although the right side of the scrotum has been destroyed by an extension of the disease from the right groin. The lymphatic glands of the left groin are very slightly enlarged, but their section does not present any remarkable appearance. Neither the iliac nor the lumbar glands, nor any of the lymphatic glands in any part of the body, are diseased or enlarged.

"There is a remarkable degree of anemia of all the viscera. The blood, wherever observed, is so watery as to be nearly void of colour. The serous membranes all feel dry and sticky, yet there is in the head a slight sub-arachnoid effusion. I collected in the pericardium a dessert-spoonful of a yellow serum; none could be obtained in either cavity of the pleura; about a dessert-spoonful is found in the pelvic pouch of the peritoneum. There is no other diseased appearance in any of the internal parts, if we except two white patches, of old formation, on the heart; one small, on the left ventricle, and one larger in the right." The lungs were remarkably collapsed.

I detected a trace of the hydriodate of potash in a small quantity of urine which was found in the bladder, but could not detect any in the serum collected from the head, pericardium, or peritoneum.

Remarks.

I have now detailed to you all the facts that have come to my knowledge respecting this interesting case. Suppose you asked me what was the disease, I should feel some hesitation in answering your question. Was it fungus hæmatodes? Was it cancer? Was it a disease compounded of those two morbid states? Or was it a disease of a peculiar kind, differing from both? Some who saw this case said it was cancer, some that it was fungus hæmatodes, and others said it was neither, that it was a disease analogous to lipoma of the testis. In some respects it resembled cancer; in some fungus, and in others it differed from both. The period of life at which it occurred gave as great a right to cancer to claim it, as it did to fungus. The one seldom appears earlier than the age of this patient, the other seldom later. The wartlike aspect which the disease presented on the prepuce, was more with cancer perhaps than with fungus. The tumour in the groin had also, before the skin gave way, so far as I could learn, much more the hard or stony character of cancer, than the soft elastic feel of fungus. The granulations which formed during the progress of the disease, and which showed a disposition to cicatrize, had

an appearance which belongs much more perhaps to cancer than to fungus. It is indeed considered, by a good authority on this subject, Sir E. HOME, to be one of the strongest characters of carcinoma, if taken in conjunction with the fungous state and destructive actions in other parts of the sore. The insulated character of the disease was very remarkable. Neither the lymphatic system nor any other part or viscus of the whole body, seemed to have suffered beyond the immediately engaged parts. The roots of the disease did not even ramify at all among the subjacent or surrounding parts. In both these respects it differed from the course which cancer, as well as fungus, in general, pursue. Although there was some discharge of blood from the fungus in the groin, it was by no means in such quantity as often occurs in both carcinoma and fungus, but particularly in the latter. Before the diseased mass began to shrink away, when the dressing adhered to any part, a small drop of sanguineous fluid would sometimes exude, but not perhaps in greater quantity than would occur from a common granulating sore, if there was an adhesion between its surface and lint which had been placed on it; and the hemorrhage which occurred on one or two occasions, when the disease was in its more advanced stage, was not from capillaries, but from vessels which had been opened by the destructive process. On the whole, I should be disposed to say, that we must either consider it specifically different from both cancer and fungus, although it certainly belonged to their genus, or else we must extend our views respecting the characters of these diseases, so as to make our definition include the case which we have been considering.

The more important practical points connected with the subject relate, however, to the diagnosis of the disease in its early stage; and to the cause of the changes which occurred while the patient was under the action of the hydriodate of potash.

There can be no doubt but that when the disease commenced, it was mistaken by more than one person for a venereal affection; nor do I wonder at this when I reflect on the

General want of Accurate or Scientific Knowledge of the Appearances of Venereal Diseases,

and how much our education tends to induce us to suppose that every sore on the penis, particularly if accompanied by a tumour in the groin, is venereal. If the disease on the inner surface of Keogh's prepuce had at all the appearance of either of the small diseased spots or patches which were on the outer surface when I first saw him, no person who was not versed in the nicer shades of distinction could have been certain

of its nature. The more minute spot was like the venereal sore which I have described in my treatise on the venereal disease, by the name of "fungous syphilis following excavated ulceration;" and the large patch equally resembled the sore called by me "white phagedenic syphilis." Can any case show in a stronger light the necessity of giving attention to the diagnosis of primary venereal affections? I could detail to you numberless cases in illustration of the great ignorance which prevails even among otherwise well-educated medical practitioners, respecting these diseases. Here is a drawing of the penis of a patient sent to me from a distant county, and represented as a case of obstinate venereal sore. It is a case of well-marked incipient cancer. Within the last week I was consulted by a married lady, for an eruption. She had been under the care of several practitioners. The eruption was a well-marked venereal eruption, which she had contracted from her husband, to whom she had been married about a year and a half; but its nature was never suspected, and the treatment adopted had been of no use to her. You will not feel the importance of a knowledge of the venereal disease until you go into practice, and then such of you as have not attended to it will regret the opportunities you have lost. "Oh! we are not examined on these subjects for our degree; what is the use therefore of taking up our time with such things?" I have been hearing this kind of remarks, on various important subjects of medical study, for several years. I vainly hoped that such a change would long ere this have taken place in medical education as would have led pupils to give sufficient attention to practically useful subjects, but that change has not as yet occurred. I am convinced I do not exaggerate when I say, that not one third of the stuff with which pupils are, for the sake of their examination, called upon to cram themselves, will be of the slightest use to them hereafter, while they often neglect those subjects which they should attend to, and that because they are not the subjects of examination. Time will no doubt bring a remedy for this crying evil, and I hope the time is not far distant. I admit that the objects which require the attention of the medical student are very numerous and complex, but I am convinced that by a proper system of education, vastly more may be done than is done, and with vastly less trouble. But to conclude, What was the cause of the

Extraordinary Change which took place in Keogh's Case?

Was it a change brought about by the natural progress of the disease, or was it the result of the action of a remedy, the extent of whose power we do not as yet know? In my opinion the latter was the case, and I will

tell you why I have formed this opinion. In the first place, from my knowledge of the powerful influence of the hydriodate of potash in many forms of disease, I do not feel surprised at its producing a change such as occurred in Keogh's case. Look at the case of a woman in No. 8, the whole surface of whose body was, as it were, riddled with foci, or ill-conditioned ulcerated excavations, under which she had laboured for many years, and for which she had been treated in all the hospitals in Dublin. See the change which has been produced in her state by this medium; but I shall forbear enlarging on her case now, as I propose to make it the subject matter, with many others, of future consideration. In the second place the change in the disease of Keogh was quite synchronous with the action of the remedy. Very soon after the medicine was exhibited, the painful condition of the fungus subsided; and as soon as the system was saturated with it, the diseased mass began to melt away. In the third place, the destruction of parts which occurred was quite different from that which not unfrequently occurs in malignant fungous diseases, as well because it happened at the same time in every part of the diseased surface, in both groin and penis, as because it proceeded in a most gradual manner. It was much more a process of softening than a process of sloughing.

If the change which occurred in this case was owing, as I firmly believe it to have been, to the hydriodate of potash, a great field for hope, and for investigation in the treatment of these malignant diseases, is, as I have already said, opened to us; and I shall certainly lose no time in investigating the subject upon every proper opportunity. You are aware that within the last few days I have admitted into the ward No. 8, a woman, Mary Hudson, who labours under a most extensive and malignant ulcerated disease of the breast, accompanied by enlarged axillary glands. If we credit her statement, and the appearance of the part fully justifies it, the torture that she suffered for the two years before her admission has been of the most insupportable kind. This case has appeared to me well suited to a trial of the plan which I adopted in the case of Keogh. I consequently ordered the hydriodate of potash a few days ago, and I have experienced no small gratification by finding that her pain has been already much diminished. Sincerely do I hope that this change has been produced by the action of her medicine. A short time will decide the question. I hope you will attend closely to the phenomena which may occur. To excite your attention to her case has been one of my objects in choosing the case of Keogh for the subject of this morning's lecture.

It was my intention to have made some

remarks this morning on the necessity of avoiding in the employment of the hydriodate of potash, and on the cautions which have restricted the therapeutic applications of iodine, and more particularly on the impropriety of employing internally either free iodine, or the ioduretted hydriodate of potash,—the preparation so strongly recommended by Lugol. But, as our time has expired I shall reserve what I have to say upon these points for a few days, and leave my intention to commence a paper on the Skin Infirmity, a review of more than one hundred and twenty cases of syphilitic disease, which have occurred between the two institutions, and the treatment of which, by the hydriodate of potash, I have made the subject of investigation. Let me add that I have derived results which I have much reason to expect will excite great interest. It was a desire on my part to complete this investigation, in which I have been now engaged for more than two years, which has hitherto delayed the publication of the second volume of my work on the venereal disease.

HOPITAL DES ENFANS MALADES, PARIS.

RESEARCHES INTO THE DISEASES OF CHILDREN,

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND
PATHOLOGY.

TYPHUS FEVER IN THE YOUNG.

(Concluded from page 861.)

CASE 3.—Zoe Guilbert, 14 years of age, of good constitution, and apparently strong, was received into the hospital on the 4th of December, 1834; her disease dates ten days; the patient, who was born in the country, has lived at Paris for the last twelve months only; she works in a large shop and sleeps in an airy room; during the first year of her arrival at Paris she did not experience the least disturbance in the digestive organs; however, at the end of November, without any appreciable cause, she was seized with headache, and pain in the abdomen. These symptoms were soon joined by an unusual sensation of fatigue, a remarkable diminution of the appetite, nausea, and loss of sleep. The patient has not had any epistaxis, but she frequently observed some blood when she blew the nose. On the 2nd of December, constant fever; prostration; exasperation of the headache; pain of the abdomen; she child was now confined to bed, and placed on diet; no remedies of an active nature employed. On the 5th of

December the patient presented the assemblage of symptoms which constitute what is commonly called the inflammatory fever; face red and animated; eyes brilliant; headache; pulse hard and accelerated, 120; skin hot; abdomen painful; no diarrhoea; the only remedies ordered were an emollient drink and strict diet. In the evening the patient was seized with violent delirium; this persisted all night: the child got out of bed continually, and traversed the wards uttering loud cries; it became necessary to confine her in bed with the strait-waistcoat.

6. Dorsal decubitus; stupidity without prostration; the hearing is dull; the headache persists; the conjunctivæ are injected; she answers shortly but correctly; the tongue is covered with a sort of clammy fur of a grayish colour; breath foul; deglutition is easy; thirst excessive; complete loss of appetite; no nausea or vomiting; abdomen free from pain, and marked by two or three rosy spots; only one stool for the last twenty-four hours; pulse regular and soft, 120 as in the evening; the skin still warm and dry; the respiration slightly accelerated, is 36; cough; râle sibilant equally audible at both sides of the chest. The patient remained pretty calm until two o'clock, but she then commenced to sing, and disturbed the whole ward by constant cries; the delirium and agitation continued until the following morning.

7. The patient is now in a state of prostration; the face has an expression of stupidity, and the deafness is more evident; she answers slowly; the rose-spots are very numerous over the front of the abdomen and chest. The state of the tongue is the same as yesterday; no stool; pulse 120; respiration 30; a pain is felt under the sternum and in the abdomen; the cough and râle sibilant are the same as before; the nature of the disease was now evident; the patient was ordered a bottle of Seidlitz water, to be taken in glassfuls every three hours.

8. The delirium has been just as violent as in the former nights; the patient has taken the whole bottle of Seidlitz water, which produced only two evacuations; the skin is now more dry than before, but not more warm; the tongue trembles when put out, and presents the same characters of colour and dryness that we have already noticed; the abdomen continues painful, but without meteorismus; the cuticular spots are numerous; pulse 116; respiration 40. Continue the remedies.

9. The evacuations have become more numerous; the abdomen is a little tympanitic, but less painful; the patient, whose intelligence is now clear, affirms that she does not suffer any pain. The sense of hearing is still more obtuse; there is some ringing sound in the ears; the prostration

of strength is now more marked; the patient can sit up in bed with great difficulty; pulse 124; respiration 48; cough frequent; râle subcrepitant on the right side of the chest behind, but no diminution of sonority. *Continue the Seidlitz Water, and alternate it with an infusion of Marsh-mallows.*

The delirium, which for the last ten days existed only at night, now broke out during the day time with great intensity. The patient left her bed, and ran about the ward with a tottering gait, causing great alarm amongst the other children.

10. The number of evacuations is still increased; some have been passed involuntarily. The patient says the abdomen is free from pain, but moderate pressure causes a contraction of the muscles of the face, and evident suffering. There is now no delirium; the patient only feels the head heavy. A discharge has taken place from the left ear, and the sense of hearing is almost completely abolished; the rose-spots still continue, but we do not observe any sudamina; the cough is less frequent; the respiration not so accelerated; pulse 120; respiration 24. *Three Glasses of Seidlitz Water.*

11. Less delirium this night; the diarrhoea persists, and the stools are generally passed without consciousness; the lips are dry and cracked; the tongue clammy, but without any crust; the abdomen is moderately sensible to pressure; the points most sensitive are in the epigastrium and right iliac regions; pulse 124. *Continue the Seidlitz Water.*

From the 12th to the 17th day, on which the use of Seidlitz water was suspended, the patient became gradually better; the pulse fell from 120 to 108; the skin lost its dryness. The delirium went off, and the sleep returned insensibly. On the 14th we observe a few sudamina on the neck; the stools are no longer involuntary, and the number diminishes by degrees; the slight pain which occupied the right side of the abdomen has disappeared.

18. On making the visit, we find the patient sitting up in bed; the expression of the countenance is now natural; the intelligence perfectly clear; the hearing no longer dull. The patient sleeps quietly during the night; the muscular force is nearly recovered. The patient can walk about, and she seems nearly as fat as when admitted into the hospital. The tongue is now moist and clean; the appetite good; abdomen free from pain on pressure; no cough; pulmonary expansion good; pulse now 108. The patient complains of severe pain in the right ear. *Three Leeches behind the Ear; Broths.*

20. A purulent discharge from the right ear has set in. On the 21th the patient got up for the first time, and took some solid aliment. The state of convalescence progressed to the 28th, when she was seized

with fever and general malaise, without any vomiting. These symptoms continued for two days, and terminated next day by an eruption of the small-pox, which is very benign, although the girl had not been vaccinated. On the 5th of January the fever, which had fallen since the eruption, returned, and persisted for two days. *5th.* Desiccation is general. The patient was now vaccinated, but without any result.

15th of January she left the hospital. Completely cured.

CASE 4.—*Paul Confiant*, 8 years of age, born at Paris, of a delicate constitution, was brought to the hospital on the 18th of November in a complete state of delirium; on the following morning we ascertained that the child had been eight days ill. The night had been passed in a state of excessive agitation. He made water in bed, but had no stool. The child now lies in a state of stupor. The intelligence is dull; the tongue red and smooth; thirst great; febrile movement very intense; several rose-spots on the abdomen; but pressure seems to give little or no pain; the bowels are constipated. The physician ordered a bottle of Seidlitz water to be taken during the day; this produced six stools; one vomiting; delirium during the night.

20. The fever is now more intense; in the evening the pulse was 120, it has risen today to 130. The tongue, however, is not more dry; the abdomen is but slightly tender; there is a little meteorismus. The quantity of eau de Seltz is reduced to three glasses. 21st. The stools are very frequent, and the abdomen is more painful on pressure than it has hitherto been. The febrile action is very intense. *Suspend the Seidlitz Water.*

From the 22nd to the 27th, the fever continues, and is accompanied every evening by a paroxysm, during which the patient's intellectual faculties are completely lost. The diarrhoea persists equally; two or three liquid stools every day. No active treatment is had recourse to. The physician is content with ordering a cooling draught.

28. We observe numerous sudamina on the neck and chest. The skin is now moist, and the pulse has fallen to 104; the patient passed a quiet night. During the following days the symptoms gradually declined. The patient was allowed to take some solid food, and on the 10th of December she was discharged from the hospital perfectly well.

The above cases, and those which were described last week at pages 859 and 860, cannot be arranged under any other head than typhus fever, although, so far as we know, this latter affection has never yet been described by systematic writers as at-

tacking children at a very early period of life. However, the more we examine the cases of children, the more we are convinced of the truth of the proposition laid down by M. GUZMANT, viz., that children are subject to all the diseases of adults, and, in addition, to certain maladies which are peculiar to their tender age. Thus, in the course of November last, we had occasion to observe the case of a boy, eight years of age, affected with an anastomosing fistula at the root of the scrotum, not the result of an accidental lesion, but produced in a gradual manner, like the fistula caused by stricture in the adult. Another case, not less rare, presented itself on the 18th of December, 1835. A boy, fourteen years of age, was brought to the hospital in a state of extreme weakness; pulse 110; violent pain of the abdomen; twenty to twenty-four stools in the day. The patient died in a few hours after his admission, and, on examining the body, the abdominal aorta was found to be the seat of three large false aneurysms; the superior of which, placed nearly on a level with the kidney, had given way, to the extent of a couple of inches. About the same time, a case of cancer of the abdomen was observed in the "service" of M. JADELOT, in a child six years of age.

The four cases we have detailed are sufficient to indicate the general characters of typhus in the child; the symptoms, indeed, seem to differ very little from those which mark the disease in the adult; there is the same prostration of strength, the same derangement of the intelligence without any sign of cerebral inflammation—in a word, the same tendency to adynamic and ataxic symptoms; however, the affection is, generally speaking, a much milder one in the child than in the adult; the mortality is much less for the former than for the latter, but the march of the disease is precisely the same, and after death we find the same lesions in the intestinal canal.

The treatment adopted at the *Hopital des Enfants Malades* is, in general, extremely simple, and differs widely from that which is pursued in England. M. GUZMANT commences by applying a few leeches to the abdomen (if the child be at all tender), and pursues what may be strictly called the "expectant method," consisting of cooling drinks, and a sinapism now and then to the legs. If, however, ataxic symptoms

manifest themselves, he orders a tepid bath, with cold affusion on the head, and applies blisters to the thighs instead of sinapisms. The adynamic symptoms are rarely treated, as they are very far advanced. A lavement, with quinine, is then thrown up the rectum, and a few spoonfuls of Bordeaux or Malaga wine are given every now and then.

M. BAUDELOQUE is the only physician who employs the purgative method, so much in vogue in England since the publication of the work of HAMILTON. The medication he administers in preference to others is Seidlitz water. The advantage of purging, however, has appeared very doubtful, especially in the last few months, during which a tendency to dysentery has prevailed amongst the patients. In several cases the administration of a few spoonfuls of Seidlitz water, determined severe purging and dysenteric symptoms, which eventually carried off the patient. It is hardly necessary for us to make any farther remarks on this subject, we shall therefore merely observe, in conclusion, that, on examining the bodies of children which have been cut off by this disease, we have never yet discovered the least trace of inflammation in the cerebro-spinal system. The stupor, the delirium, and the convulsive movements, are merely sympathetic phenomena, and certainly are not connected with an organic change of the brain, yet how often do we see the whole attention of the physician directed to these symptoms!

P. H. GREEN.

APHONIA

OF TWELVE MONTHS' DURATION SUCCESSFULLY TREATED BY
TONICS AND REPEATED BLISTERING.

To the Editor of THE LANCET.

SIR,—From the following case we see the necessity and utility of a sufficient continuance in any line of practice we may deem requisite in chronic affections. At an early period of the disease, the patient had been twice blistered and had also used tonic medicines, but unfortunately they had been discontinued too soon. If, therefore, the publication of this case in your valuable Journal be in the slightest degree the means of restoring to any other similarly situated individual

that faculty which places us to each other in the relative capacity of social beings, my object will be fully accomplished.

I am, Sir, yours &c.,

JAMES INGLIS, M.D., M.R.C.S.E.
Castle Douglas, Feb. 23, 1836.

Jean Gibson, æt. 22, of a healthy and rather plethoric habit of body, was three years ago seized with cholera, during the rage of that epidemic. The attendant surgeon using large doses of calomel for the removal of this disease, poured into her a double portion in consequence of a relapse. Ptyalism to a considerable extent followed, and she continued extremely weak for a long time afterwards. Recovery to health gradually took place; and she continued a servant to a family in the neighbourhood, until, being exposed to the cold night air, about the end of last February, she contracted a cold, accompanied by a considerable degree of sore throat. On Saturday (the day following the exposure) she complained more of the throat, and got hoarser towards the afternoon, which hoarseness continued to increase till the Monday morning, when the voice entirely left her.

In consequence of this attack she left her place and returned home; but feeling herself much better at the end of a fortnight she again entered service. For several weeks the throat annoyed her, but at length, without using any means, it got quite relieved, so far at least as pain was concerned. From that time to the present she has enjoyed good health, every function of the body being normally performed, with the exception of that of the organ of voice. In the month of June or July she applied to a gentleman of considerable note, who, after trying the effect of several remedies, at last dismissed her with the consolation that the voice would never again be restored. After this, several medical men saw her, and had administered tonics, expectorants, acids, sarsaparilla, iodine, &c. &c.; she had also been twice blistered, but all with a similar result, so that the conclusion was that the profuse exhibition of calomel being the cause, the disease could never be remedied.

It was under these circumstances that during some part of the month of November she first applied to me. On reviewing her case, I considered that the mercury could not have been the cause, inasmuch as two years had elapsed since its exhibition, whereas had it really been so, the effect would have been much sooner apparent. My opinion was that the loss of voice arose from a thickening of the laryngeal mucous membrane, and atony of the vocal chords, the consequence of inflammation, now chronic, and that if that could be overcome the speech would be restored. For this purpose I recommended repeated blisters along the larynx and trachea, one every fifth or sixth

day, as soon as the surface would admit of application. At the same time she was ordered to brood, and to take internally every morning one of the following powders. *R. Carbonatis Plant. Precipit. ʒi; Colombe ʒij; Pulv. Aloe ʒj. M. et divide in pulv. xvij.* After taking these nineteen powders, and blistering three times, I thought I could discover some improvement, I therefore repeated them, with the addition of ʒj of guaiacine, and ordered a continuance of the blisters. She remained nearly in the same condition, till after having taken the thirty-sixth powder, and having blistered six times, the voice was restored, and she now speaks with all that freedom and volubility which characterize her sex.

AMENORRHŒA.

A CASE of amenorrhœa successfully combated by the application of sinapisms to the mammæ, is related by M. HULIN-ORIGET, Secretary to the Medical Society of the Indre and Loire, in France, in the *Revue des Journaux de Médecine* for August last. The number of analogous facts are so considerable, that no doubt can remain with regard to the suitability of the means in numerous cases of amenorrhœa, and now that their efficacy is rendered so unquestionable, it only remains to state the description of cases in which the sinapisms may be employed with hopes of success, at the same time indicating those in which this measure is contra-indicated, for we do not expect that all obstinate cases will be so treated with equal advantage. At present we shall simply give further circulation to the new fact which we have above mentioned, in addition to those which are already known.

Case.—Josephine B., aged fifteen years, of a lymphatico-sanguine temperament, and having a good constitution, had had her catamenia only thrice since her eleventh year. In the spring of 1832 she was seized with convulsive motions of the arms and wrists, in consequence of profound grief and sudden alarm. Some days afterwards she was unable to move the left arm, which, at the same time, was affected with excessive sensibility, and so continued for two months, though antispasmodic medicines and camphorated liniments were frequently employed. Three months afterwards both legs became paralytic, successively, and continued in that state for ten weeks, not being relieved by the application of leeches to the thighs, nor by frictions with ammoniated liniment upon the legs. In

April 1833 she experienced a new and violent attack of the legs, which diminished after she had been seized with vomiting of blood in small quantity. In the winter of the year 1836, she had a most severe attack of angina tonsillaris, and afterwards a paralysis of the left leg, accompanied by an intolerable pain over the tract of the sciatic nerve of the right leg. She was relieved by one blood-letting, but not cured thereby.

She was in this situation upon the 22nd of February, when the reporter states that he attempted to restore the flow of the catamenia by irritating the mammae in the manner proposed by Dr. Mondière. Two cataplasms, prepared with five ounces of mustard, were applied to the outer and external sides, and also to the superior portions of the mammae. The severe pain which she experienced in about fifteen or twenty minutes after the application, forced her to remove these cataplasms, which reddened the skin, and rendered it very sensible to the touch. The next day she had a considerable flow of leucorrhœa, and the third day she had an abundant catamenia, which, instead of four, continued during seven days, as in the months of August and September. On the 3rd of April this person enjoyed good health, and walked out freely. The mammae are developed, and since the return of the catamenia she has grown in a remarkable manner. We think (adds the author of the case) that this salutary revolution was hastened by the augmentation of the vital activity of the uterus, and is attributable to the artificial irritation of the mammae.

HOUSE OF COMMONS.

March 1, 1836.

MEDICAL WITNESSES BILL.

MR. WILKES said, that before the Honourable Member for Finsbury rose to make the motion he was about to submit to the House, perhaps the House would allow him (Mr. Wilkes) to present a petition on the subject of that motion. The petition was from Mr. Baker, a surgeon and apothecary, residing at Hoxton, in which document the petitioner made the following statement. On the 22nd of July, 1835, the petitioner was requested to undertake the post-mortem examination of a person who was supposed to have been murdered. He attended before the Coroner, who postponed the examination until the following day, in order that the examination might take place, and on the following day the petitioner was requested to submit the contents of the stomach to analysis, to allow which, the

inquest was again adjourned for three or four days. The analysis occupied several hours of several days of this professional gentleman's time, and subsequently the petitioner gave his evidence, when the Coroner and the jury felt that he was entitled to remuneration, and unanimously expressed their approbation of the intelligence and talent he had exercised on the occasion, and their gratitude to him for the assiduity he had manifested, at the same time recommending to the parochial authorities that he should be paid for his professional attendance and labour, the ordinary charge for which would have been ten guineas. However, he only applied for three guineas, when the answer was, that they had no power to make him any compensation whatever, out of any fund over which they had control. Under these circumstances the petitioner felt that the Legislature ought to interpose, giving power to the Coroner to award to professional men some remuneration when their time and talents were thus drawn upon. (*Hear, hear.*) He (Mr. W.) knew perfectly well, that by far the greater proportion of professional gentlemen were decidedly convinced, that for the ends of justice a remuneration of this nature ought to be provided. A petition was in the hands of his honourable friend, the member for Southwark, signed by several hundreds of the physicians and surgeons of this metropolis, in favour of that provision, and, undoubtedly, the case urgently required legislative interference.

The petition was then ordered to be laid on the table.

SIR JOHN R. REID said, that he also had a petition to present on the subject. It came from the medical gentlemen of Ewell, in the county of Surrey, requesting that the House would take into consideration the difficulties with which they had to contend as witnesses at coroners' inquests, and praying the House to provide a fair remuneration for their trouble. He entirely concurred in the sentiments expressed by the hon. Member who had just sat down (*hear, hear*), and he had no hesitation in saying, according to the view he took, that no individuals in society were so badly paid as gentlemen in the medical profession. (*Cheers.*)

The petition was ordered to be laid on the table.

MR. BARCLAY said, that he also had had a petition entrusted to him for presentation from medical gentlemen in a town in the county with which he was connected, and which he regretted much he had not brought down with him to present on this occasion. The petition was to the same effect as those which had just been presented, and his own opinions upon the subject entirely concurred in those which had already been expressed. (*Hear, hear.*)

Mr. D. W. HARVEY said, that he had a petition to present, signed by 526 gentlemen, all of whom were distinguished for their professional eminence in this metropolis. Indeed, he should think it invidious to select any names from amongst them, except merely for the purpose of stating, that amongst others it was signed by the presidents and the vice president of the Royal Colleges of Physicians and Surgeons, Sir Astley Cooper, and Sir Anthony Carlisle, who all stated that great inconvenience as well as great injustice had occurred, in consequence of the absence of a compensation to medical gentlemen who were called upon to attend at coroners' inquests. He trusted that the bill, which his hon. friend the Member for Finsbury was about to introduce, would, under these circumstances, be successful in its passage through the House. (*Hear, hear, hear.*) He had also a petition to present, signed by sixty-five professional gentlemen, resident in the Borough of Southwark, to the same effect.

The petitions were ordered to be laid on the table.

Mr. WAKLEY.—Sir: From the very favourable manner with which the House has been pleased to receive the petitions which have just been presented, I am sure I shall not have occasion to occupy your time for more than a very few minutes in explanation of the nature of the Bill which I wish to introduce. When, last year, the County Coroners Bill was before the House, the House will recollect that it contained a clause professing to provide for the remuneration of medical witnesses at inquests, which clause, however, shared the fate of the whole of the Bill, the Bill being rejected by the House; and, I think, very properly, for it was perfectly inequitable to the objects which the honourable Member sought to attain. I am ready to admit that medical gentlemen may not, in some respects, be more useful when they attend as witnesses than others, but it should be borne in mind that medical men attend the Coroner's inquest in their professional capacity. They do not attend as casual observers of the event which may have occasioned the inquest; but as professional men, who alone can give that information which is essential to the ends of justice and the basis of a true verdict. The duties which medical men have to perform are exceedingly important (*hear, hear*); they are very difficult of accomplishment, and very frequently attended even with danger to life. A post-mortem examination is not to be conducted in haste, or without science and trouble. Many instances within my own knowledge have arisen where a post-mortem examination has necessarily been protracted through a period of eight or ten hours, and yet where the medical witnesses who conducted it, and gave evidence of the facts

discovered, obtained no kind of remuneration, the Coroner having no power to award the slightest compensation. Now, Sir, these points of things which ought not to be allowed to continue. (*Hear, hear.*) I can assure the House that the present deficiency in the law is not so insignificant to the medical man as to the public at large (*hear, hear*), because it entirely defeats the object which the public have in view in upholding the Coroner's inquest, which is one of the most important offices in England, and almost the only office to which the people have still the power of electing their own judge. Yet unless that judge be invested with the power to give compensation to medical witnesses, I do think that the Court has a tendency to become almost useless. (*Hear, hear, hear.*) When the Coroner calls a medical man before him, he has not the power of requiring the witness to make a post-mortem examination, although the result of that examination may be the only disclosure which can enable the jury to return a correct and faithful verdict. Within a very short period several inquests have been held in this metropolis upon the bodies of persons who have died under very extraordinary circumstances, and I may mention that quackery at this moment (*hear, hear*) is producing more victims (*hear, hear*) than it ever did at any former period. (*Hear, hear, hear.*) It is fearful to observe the consequences which flow from the advertisements of quacks with which the newspapers teem (*hear, hear*); and I should be glad, indeed, if His Majesty's Government would resolve on the removal of those disgraceful outrages upon society, by preventing quack medicines from going forth to the public under the authority of Government stamps. At an inquest held a few days ago, the circumstances of which have excited great indignation, several medical men attended, all of them, of course, without obtaining compensation. Had they been selfish or mercenary enough to refuse to attend, or had they withheld their information as professional men, what verdict could have been returned? How completely might justice have been defeated on that occasion! And how frequently do similar instances occur! Now, Sir, when we take these points into consideration, and observe the anxiety of the people to have faithful verdicts recorded, I do trust that the House will not refuse to grant that compensation to medical witnesses which will be ensured by the passing of this bill. As I am sure, from what I have observed to-night, that the principle of the bill will be sanctioned by the House, I shall not at present enter upon its details, but merely, with these observations, move that leave be given to bring in a bill to provide for the payment to medical men who may attend as witnesses at coroners' inquests.

Mr. ATTORNEY GENERAL.—Sir, from my experience I will venture to say that the Bill for the bringing in of such a hon. Member for Finsbury has now moved, will be exceedingly useful. (*Hear, hear.*) I have known several cases where public justice has been obstructed in consequence of competent medical evidence not having been given before a Coroner's jury. Juries either are without that evidence altogether, or, when it is obtained, the injustice of refusing to award a fair and honourable remuneration is committed. (*Hear, hear.*) I would only suggest to the hon. Member in bringing in this bill, to take care to have it so framed that it shall not be made the means of a job by the coroners themselves. (*Hear, hear.*) Coroners have before now made a job of their office, and unless care be taken they will make a job of this, by calling in a medical friend, and giving him a couple of guineas where there may be no necessity whatever for his evidence. With that caution against abuse of this kind, I certainly do think that where medical men are called in, on fair occasions, they ought to be properly compensated. (*Hear, hear.*)

Sir ROBERT INGLIS thought it might be desirable to know from what fund it was proposed by the hon. Member for Finsbury that the medical gentlemen should be paid? Was it proposed to throw the payment upon the parish or the county?

Mr. WAKLEY considered that it would be better not to enter into a consideration of any of the details at present, though he did not object to saying that in his opinion the payment ought to come from one of those two sources. On seconding the motion,

Mr. WASHINGTON said that of course the hon. Member for Finsbury would take care in the bill that professional gentlemen were paid for their attendance; but looking at cases where the talent of persons of superior information was called into action, where their materials and apparatus were required in an analysis, he should think that the compensation would fall short of what it ought to be, unless there was reference had to the expense of the education of the individual. (*Cheers.*) It seemed impossible that the parish could have refused to pay the petitioner in the case detailed by the hon. Member for Boston, but having refused, he would advise him to present himself at the Home Office, and inquire if the justice of the country was to be defeated because he could not afford to give his time and labour in the manner required, or whether a fair remuneration would be made to him. Until such a bill as his hon. friend, the Member for Finsbury, proposed to introduce, became the law of the land, he should certainly recommend medical witnesses, much of whose time and attention was required in Coroners' courts, to apply

at the Home Office for payment for their services. (*Hear, hear.*)

Sir GEO. STRICKLAND said, that he was quite favourable to this bill being brought in; he was very sure that such a bill brought in by the hon. Member for Finsbury would be passed into a law. (*Hear, hear, hear.*) If, however, what the hon. Member for Bridport had suggested, was carried into effect, a principle would be raised which could not be satisfied in the quarter mentioned, from want of proper funds, in consequence of which the applications for remuneration could not be complied with to the proper extent which the services of well-educated medical men would require. (*Hear, hear.*) The hon. Member who had brought forward this measure ought to take care that a proper compensation was provided in the bill. He (Sir G. S.) well knew the liberality of the medical profession. (*Cheers.*) He believed that no class of individuals in society devoted so large a portion of their time, and underwent so much trouble, for the public, and for the poorer classes especially, and he was quite sure that neither the public, nor the legislature would raise any objection to a remuneration, on all proper occasions, being provided for such men (*hear, hear*); and he was quite satisfied that those gentlemen who devoted so considerable a portion of their time so liberally for the public good, would be satisfied with a small remuneration for attending at Coroners' inquests; but remuneration they undoubtedly ought to have.

The Hon. A. TREVOR (who was almost inaudible in the gallery) said, that he could not forbear expressing the great satisfaction he felt at the honourable Member for Finsbury having given notice of this important measure. All men must be agreed, that compensation ought to be provided for medical men who attended as witnesses at coroners' inquests. He knew no body of men whatever who were so essentially useful to the public, or who did anything like so much good to the poorer classes of society (*cheering*), and they were entitled to all the consideration and assistance which that House could afford them. He did not entertain any great apprehension that a measure like this would be converted into any thing like a job. (*Hear, hear.*) From what he knew of the respectability of coroners in general, he could not persuade himself that they would attempt to disgrace themselves by converting such a measure into a means of abuse, even if it were in their power to do so. Still, if that were possible, he was satisfied that the object with which the hon. Member for Finsbury was about to introduce the bill, would greatly counterbalance any evil that could result from its operation in such a way. (*Hear, hear.*) He could not allow the House to

grant leave to introduce a bill of this description, without expressing his most anxious hope that it would be passed into a law.

Mr. JERVIS said, that he was not about to make any objection to the introduction of the bill, he only wished simply to observe, with respect to the existing law, that if a coroner desired to have the attendance of a medical man at an inquest, and issued his warrant to the parochial officers, calling on them to send a medical witness, and they did so, that medical man would undoubtedly have a claim upon them for compensation, which he could enforce. He believed that no doubt existed on this point, and if the hon. and learned Member, the Attorney General, would take the trouble of looking into the old law affecting the case, he would find it to be as he (Mr. J.) had stated.

Sir J. R. KIN was understood to say, that he did not believe that the petitioners whose petition he had laid on the table, did so understand the law, but, however that might be, it became the duty of the Legislature to put the right of medical witnesses to compensation beyond dispute, or difficulty. (*Hear, hear.*)

Mr. SOLICITOR GENERAL said that he knew many cases in which medical gentlemen had been summoned to give evidence at Coroners' inquests, without being able to obtain any remuneration whatever. This was, undoubtedly, a great hardship. In some of the instances they had had to travel a long distance, and give up a very considerable portion of time. The bill now about to be introduced, was one in which the medical profession at large took a very great interest; and although, perhaps, strictly speaking, as had been stated by the hon. and learned Member opposite (Mr. Jervis), medical witnesses might, at present, have a legal right to claim compensation, yet he knew of no means by which the law could be enforced, and as the bill of the hon. Member for Finsbury seemed to be admitted by all to be only a matter of right and justice to a most meritorious class of persons, he sincerely hoped that that bill would meet with no obstruction in its progress through the House. (*Cheers.*)

Mr. PLUMTREE said, that the bill should have his utmost support. As the hon. Member for Finsbury was himself a medical gentleman, he had no doubt that the provisions of the bill would be judiciously framed, and he merely wished to express a hope, that it would be distinctly provided whether the compensation was to come from the parish or the county, that there might be no difficulty or delay experienced afterwards in obtaining the remuneration to which the witnesses would be entitled.

Mr. WAKLEY said he thought that what had been stated with respect to the law of the case by his honourable and learned

friend, Mr. Jervis, would be found to be not quite correct. It was quite true that coroners might direct overseers to produce a medical man as a witness, but it was equally clear that that medical man, if he pleased, might refuse to give evidence. He might say—"I will not open the body. I will give no testimony respecting a post-mortem examination;" and the coroner has no power whatever either to compel him to make the examination, and state his opinion on the cause of death, or to commit him for a contempt of court. Now he (Mr. W.) wished to give the coroner more power; but, at the same time, as a set-off against that power, he wished to give the medical man a due compensation. (*Hear, hear.*) He would at the same time assure the honourable Member (the Attorney-General), and the House, that it would be his anxious wish to guard against the possibility of jobbing under the provisions of the measure, because jobbing was what he most cordially detested. (*Hear, hear, hear.*) He knew that in Ireland there had been much jobbing carried on under the Coroners' Bill, where five guineas had often been paid unnecessarily under the Act, but he would take care to guard against such an abuse here. With reference to what had just been stated by the honourable gentleman opposite, he could only say that he should be perfectly satisfied with the decision of the House as to whether the compensation should come from the parish or the county. (*Hear, hear.*)

Leave was then given to bring in the bill, amidst the cheers of the House.

When Mr. WAKLEY alluded to the prevention of quack medicines from going forth to the public under the sanction of Government stamps, the cheers which came from the House were heartily joined in by the MINISTERS.

CONCOURS

FOR THE ELECTION OF HOUSE-SURGEON
AT THE

NORTH-LONDON HOSPITAL.

THE election for house-surgeon to the North-London Hospital, has again been decided by *concourse*, Mr. WALLIS, the first gentleman elected to the situation on the score of *qualifications* alone publicly demonstrated, having completed the term of his duties. In giving a report of the proceedings at that election (No. 23, Vol. 2, 1834-35), we stated some particulars respecting that hospital, which it is unnecessary to repeat. It will be sufficient to say, that the office of house-surgeon to this hospital is awarded to the most approved of the competitors for the prize; every dresser of three months' standing is eligible as a candidate for the

office. The examination was not conducted in the following manner. There were four candidates. The answers were given in under cover, with mottoes:—

1st Division. The principles of treatment in surgical diseases.—*Questions.* 1. The relations of the femoral artery. What part of the vessel is preferable for the application of a ligature? State the reasons for its being so. What are the steps of the operation, and the cautions to be used in its performance?

2. How would you treat a simple fracture of both bones of the leg? How would you treat a compound fracture of the same bones? Describe, particularly, the position of the limb, and the mode of applying the several parts of the apparatus.

3. Describe the symptoms of retention of urine, as arising from enlarged prostate, and the treatment. What is to be expected if the bladder be not relieved?

4. Describe the coverings of an oblique inguinal hernia, and the relative position of the vessels and the epigastric artery to the neck of the sac.

2nd Division. The performance of those operations which are likely to be required of the house-surgeon. This and the third division were conducted in the clinical theatre before a large assemblage of students and practitioners. The questions, the reasons for the operations, &c., were written down, and a number of them were put into a hat, when one was drawn by each candidate. The operations were performed by the gentlemen successively, only one candidate being present at a time:—

1. Removal of first and second phalanges of the finger.

2. Amputation of the finger, with a portion of the metacarpal bone.

3. Application of a ligature after amputation below the knee.

3rd Division.—Actual application of apparatus, &c.

1. Name the instruments required in amputation of the leg.

2. Show the mode of reducing luxation of the humerus, when dislocated into the axilla downwards and forwards.

3. What are the appearances of such dislocation?

4. The application of bandages required in fracture of the clavicle.

The medical committee of the hospital conducted these examinations. The successful candidate was to have been named last Monday, the final examinations having taken place on the previous Saturday. On Monday, however, it was found that two of the candidates were considered to be, in every respect, equal in the scale of merit, and it was deemed necessary that those two gentlemen should submit to a *rixa-pace* examination by the surgical staff of the hospital.

in public, each of the surgeons putting two questions, which were the following:—

1. Suppose a penetrating wound of the palm of the hand required your attention, that it had bled considerably at the time, and a ligature was applied, and that at the end of six or eight days hemorrhage came on, what would you do?

2. Describe the symptoms and treatment of oedema of the glottis.

3. Describe the symptoms of dislocation of the head of the femur into the obturator foramen.

4. The symptoms of dislocation of the same bone into the ischiatic foramen.

5. What parts would you cut through, and what avoid, in the operation of tying the subclavian artery in the first part of its course?

6. Give the relations of the prostate gland, and what you divide before you come to it in the operation of lithotomy, cutting from the perineum inwards.

After these questions had been answered by the respective candidates, the committee retired, but shortly afterwards again entered the theatre, when Dr. Thomson announced, that after the most impartial examination of the papers, and a full consideration of all the proceedings, the Committee had decided on electing Mr. HONGSON, of Halifax, to the vacant office. The announcement was received with cheers. Our reporter adds, that "wishing to ascertain how far the statements were correct which are sometimes urged respecting the nervousness of candidates at public examinations, he inquired of the gentlemen who submitted their acquirements to the ordeal on the present occasion, what degree of anxiety they experienced; when he found that two of them were not at all alarmed, and that two did not experience more perturbation than they considered they might have felt, had they been subjected to the same tests in private."

CONTINUED CORRUPTION IN THE DUBLIN COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—The period rapidly approaches which will terminate the hopes and fears that have so long beset the several parties in the medical world, according as they are friends or foes to that expected renovation of our institutions, which is to abolish all monopolies, and introduce an order of things which is calculated to promote science, and secure the interests of the medical profession. All eyes are directed to Mr. Warburton. Meantime intellects of every caliber, pens of all degrees of power (and why not

minae), are in active operation; while *THE LANCET*, with a liberality and a regard to general interests, beyond all praise, affords every facility to free and fair discussion. It is devoutly hoped that all this may eventuate in a measure of genuine and general reform, one which will sweep away all abuses, and enact such wholesome regulations (uniform for the three kingdoms, conferring equal privileges in all) as shall ensure adequate knowledge in the practitioner, honourable conduct and protection in the exercise of his profession, and guarantee to superior acquirements those offices of honour and emolument which are so basely prostituted to faction or nepotism.

As regards other medical institutions, great are the difficulties that will oppose the intention of the Legislature; but it should be remembered at this important moment, that in the case of the Irish College of Surgeons, there is a field which is perfectly open for the most extensive experiment in medical reform. It is a *new* institution, which has grown up in our own times, in which there are no *ancient* abuses or privileges made sacred by the touch of time. It presents no vested rights; its corruptions, though they may be intense in degree, are but the jobs of yesterday. Here, too, a very strong and respectable body loudly demand reform. In fact, this body forms the majority of the College, if you deduct the present possessors and the gaping expectants of office, who (with a staff of unthinking retainers, men of no minds, who merely continue the habits of submission which they contracted during the servitude of their apprenticeship) alone constitute the faction. Even of this medley crew, the expectants will, without doubt, swell the number of reformers, when they perceive which way the wind blows, and that they can no longer hope to rise by the corrupt and factious steps by which their jobbing superiors have so easily obtained distinction. Thus the Irish College of Surgeons will be found most pliable, and present but little obstacle to the most thorough and searching reform.

The faction, too, deserve no mercy; for in opposition to justice, and to public opinion specially directed towards them, in the very teeth of repeated warnings, their conduct has been, and still is, marked with as great, if not greater depravity, than in the palmy days of rampant toryism; jobbing and corruption are perhaps more rife than ever; intrigue and petty party malice are still in full operation.

1. The infamous blackball still outrageously deprives the majority of the profession of their just and legal rights, Mr. Cusack's exclusive declaration being still unrepented, and superseding by-law, charter, and every thing else.

2. The same factious conspiracy still re-

sembles its Siamese officers. Witness the continued election of some, and the recent dismissal of others, who had the courage to show any symptoms of independence. Witness the appointment of Mr. Harrison, as *professor*, where he lectures in the school; as *censor*, where he examines his own pupils for license (reporting to the College on the excellent and effective condition of the school); and as *secretary*, where he publishes the results of his valuable threefold labours. Witness Mr. White as president, and Mr. Jacob as vice. Doubtless in this selection the College wished to mark their high sense of the consistent political integrity of the one, and the pure oath-regarding morality of the other, as well as the general eloquence and profound scientific attainments of both.

3. Professorships, old, new, or subdivided (a scheme to increase patronage, and present an imposing appearance in puff), are filled up according to that system which has hitherto worked so well; viz., as soon as a chair is declared vacant, the faction forthwith most industriously pass a number of by-laws, no matter how gross, impolitic, or inconsistent, which ensure the return of the favourite of corruption. It is of little consequence though he be a beardless boy, and is opposed by a gentleman of vast experience and practice; he must be elected, especially if he come from the manufactory in Park-street, whence have been drafted in latter times no less than six professorial pedagogues. This, to be sure, is but a trifle, but it serves to show what a consenting organization exists between these sympathetic Siamese twins of corruption. There are now three vacancies; doubtless two, at least, will be filled up with scions from the same prolific establishment.

4. College funds, are disposed of with the same rigid economy, the same scrupulous regard to general interests, as heretofore: for instance, two recent extraordinary expenditures, viz., one of 1804, to the curator, for his extraordinary birth of a *ridiculus mus*, which, after a marvellous gestation of ten years, he was at length safely delivered of in the shape of the *first number* of the Museum Catalogue; a work which, be it remembered, by the performance of his paid service he would have completed years back. This was characterized by the learned mover of the vote, as the most perfect, most classical, and most marvellous production of modern times; an opinion in which I regret to state, *THE LANCET*, in a review of it, had the sad ignorance and want of taste by which means to coincide. And, secondly, 1804, to Messrs. Jacob and Harrison, in order to watch his Majesty's Government, and prevent their having the audacity to grant a charter to the University of London, a matter which is likely to prove injurious to their private school, commonly misnamed

that of the College. To what an admirable pitch of perfection has the College advanced, when it enables a couple of vulgar provincial adventurers to browbeat the prime minister of the first nation in the universe! *Alas for Lord Melbourne!*

5. Business is still transacted after the old fashion, and to meet old objects. The College is variously and injudiciously pledged, and money is granted on the faith of documents, garbled in the reading; precedents are discovered, insisted on, and sworn to, to meet every occasion; order, decorum, and fairplay, which prevail in all other, even the most unlearned meetings, are here still shamefully violated and utterly disregarded. It would be invidious, and indeed difficult, to select a *single* instance.

6. Reform is still in the same ill odour, and as hateful a thing as ever. Never did juggling heads more fully break the word of promise to the hope, than did the concours and by-law *reform* committees, both of which,—after giving such dreadful note of preparation, after keeping the College on the tiptoe of expectation for nearly a year,—have, alas for the instability of human hopes! departed this life, each giving birth, with all the agonizing throes of a dying mother, to a luckless report. One, mothered by a Mr. Evanson, whose celebrity has not yet I fear extended beyond a very small, but select circle of course, recommends a premium of 50*l.* for the best essay on the concours. It is not difficult to foresee how this job will terminate, but it has the advantage, as he, poor thing, thinks, of cushioning the question for another twelve months, and throws overboard all intention, in spite of promises ad infinitum, of the concours experiment, although no less than five opportunities have already offered. The other, calved by the redoubted James Cusack, is content with recommending limits in its first (and, it is prophesied, its last) report to the College, to take no cognizance, as heretofore, of apprenticeship bargains, and also to adopt certain modifications of the half-yearly examinations; that is, the evils of both are still to be retained, for James Cusack's words are a law to a certain party in the College. Now, the examinations are notoriously a humbug, presenting an imposing aspect to the gullible public, and forcing pupils into contact with the school and its professors, to be tampered with and seduced, as has been attempted before now; while, on the other hand, they are felt as a most tyrannical hardship and inconvenience by students. By the suggested arrangement about apprentices, the whole system will continue in full operation, though not appearing on the College books; and will still be a source of immense revenue to James Cusack, and this the said James knows right well. Such are the splendid results that crown the un-

paralleled exertions of the faction in the cause of reform. It is to be feared, however, that the impatience of the Legislature will interfere with and prevent what has been commenced and continued under such very very favourable auspices. What a pity!

7. The same tender regard is paid, as heretofore, to *general* interests and measures of *general* utility; never is prejudice or partiality allowed for a moment to divert the even current of calm deliberative justice. Witness the treatment of two gentlemen, both reformers, at a very recent meeting of the College. One of them moved for a committee to consider what means might be devised to render the subjects of comparative anatomy, purchased by College funds from the Zoological Gardens, more available as sources of information to the members of the College. By the present arrangements, all opportunity of information is confined to the curator and professors of anatomy, who also, as they purchase with College money, drive all competitors from the field. All the value the members of the College derive, consists in the few preparations that result to the museum, which could probably be purchased cheaper, if all the attending expenses be taken into consideration. This, however, being a measure of general advantage and liberal consideration, was indignantly scouted by a meeting prepared to scout anything, so that the private huxtering of Mr. Jacob continues triumphant. The other reforming member tendered, in the usual form, a notice of motion to found a chair of comparative anatomy and zoology, calculated for the members and bachelors of the College. The tendency of such a motion being to establish something of value and interest to the profession, beyond the miserable and contemptible elementary school to which the selfish cupidity of the professors confines all the exertions and funds of the College, it was forthwith audaciously ruled by Mr. Vice Sec. Harrison, and Mr. President Cholera White, illegal, and actually refused as such. A notice of motion, tendered in regular form, illegal! Such a violation of all precedent, custom, and courtesy, such an exercise of tyrannical impudence on the part of Mr. White, forms a striking contrast with the dignity, urbanity, and impartiality of Mr. Read, the late president. Such an outrage, even in the Irish College of Surgeons,—and surely no other chairman would dare to act so, at least without being forthwith brought to a knowledge of his duties,—I must confess astonished me. I shall be more astonished if the member in question, who has hitherto passed for a gentleman of spirit and independence, quietly submits, without a public protest, to the ignorance, the impertinence, and the illegal proceeding of Mr. White.

But there is no end to the facts that go to prove, that the innate depravity of the faction continues unabated, and that even at this, the eleventh hour, they are without a single redeeming feature in their case. *De lenda est Carthago*. I am, Sir, your obedient servant,

SILENS.

Dublin, Feb. 27, 1836.

NEW CORPORATIONS.—MEDICAL CORONERS.

We select the following passages from the published letter of Mr. ROGERSON to the New Corporations, mentioned by us last week at page 888:—

"The municipal reform bill has, either directly or indirectly, placed in your power the local administration of justice, and the election of the officers who preside over its courts. Of these, the coroner's court is one of preliminary inquiry, and, viewed in its relations to society, occupies a conspicuous and important rank.

"Highly responsible is the execution of the trust reposed in you, and fully believing that the day is gone by, when adherence to antiquated customs prevailed over the improvements and advances of knowledge, I respectfully address you, that the coroner's court may be reformed by the application of that science, which alone can efficiently administer justice through the detection of the causes of death. The science is that of medicine."

Having reviewed the duties of the court. Mr. Rogerson says,—

"Having ascertained the first principles which govern the court, the object will be to find a class of society who can best reduce these to practice, and carry them fully into operation. Is a lawyer, whose business cramps his mind, in the study and perversion of precedents, acts of parliament, judges' versions of them, and in mechanically copying forms of law, best qualified to preside in such a court? Decidedly not,—will be the immediate answer. His professional learning and habits of life never lead him to acquire the extensive knowledge of *medical science* which is requisite for the execution of these duties of the coroner's court. So defective do attorney-coroners find themselves on this point, that they are in the habit of carrying with them to inquests a small manuscript copy, neatly and closely written, containing a list of the most common poisons, the principal symptoms following their administration, and a short description of dangerous wounds, and of the appearances of the body from drowning,

hanging, &c.* How miserably defective must that inquiry be, when the highest authority and chief director of a court is obliged to consult so imperfect a document, before he can proceed with, and continue an examination, which may put the life of a fellow being in jeopardy, and may perchance destroy, what may be dearer to him *his reputation*! His medical ignorance necessarily prevents him from safely, justly, and properly conducting this inquiry."

"An objection, deceptive without the merit of plausibility, may be offered against the absolute necessity of appointing medical coroners. 'These inquiries, important and necessary as they must be admitted, can be obtained from a medical witness.' A coroner is present at every inquest; a medical witness sees very few of them, and at the majority of these few, the assistance of a medical practitioner is, according to the present practice, required only on account of some glaring suspicion, or strong communication, which stupidity itself could not overlook. Are the great majority of deaths on which inquests are taken, and the causes of which are unenlightened by medical witnesses, invariably unattended with suspicious circumstances? A great number of sudden deaths, requiring inquests, are suspicious, and a medical coroner, who, by the nature of his profession, is best acquainted with the *causes and appearances of death*, is enabled at once to decide on the truth or falsity of these suspicions, and on the necessity of instituting a right examination by a medical witness. A coroner, with a smattering of knowledge, or with a total ignorance of medical science, will most certainly commit errors. One fact is said to be worth a thousand reasons, and among the number supporting the truth of this last position, I will offer the following, related by the late Mr. Hunt, which occurred during his confinement in Heberstoe jail:—A prisoner died at eleven o'clock in the morning, and on his body an inquest was held by a non-medical coroner, under whose direction a verdict was returned of accidental death. It was afterwards proved on oath, before the Commissioners of Inquiry, that the unfortunate man was killed by a blow inflicted by one of the turnkeys, who had chained him by the neck to the wall for rioting and drunkenness, and was irritated by his abusive language. An error so egregious as this could not occur with a medical coroner, for the view of the body required by our laws

* One of the coroners for Middlesex goes beyond this. He carries with him an unabridged copy of "*Buchan's Domestic Medicine*," and appeals to it for information, and correction of the medical witnesses, on all doubtful occasions. It was in constant use at the late inquest on the body of Capt. Mackenzie.

would soon inform him of the necessity of directing this inquiry to be conducted by anatomical examination and further verbal investigation. The election of a medical coroner for the county of Somerset was the first step towards an investigation of the abuses in Ilchester jail."

Mr. Rogerson proceeds to argue various other questions, and thus illustrates some of them:—

"General truths acquire additional force by the illustration of example; and the inability of non-medical Coroners to estimate the validity of evidence on, and conduct an examination relating to, scientific questions on death, is shown by the 'CASE of the unfortunate Eliza Feunings. It was stated that the knife, which was a steel one, and which she had used to cut a pudding, was made black by that act, and that, therefore, the pudding contained a combination of arsenic. This, too, was asserted by a medical witness, and was the strongest evidence against her; but this combination of arsenic could not blacken steel. The Coroner knew not this chemical fact, and could not therefore discover the necessity of other and better evidence on this point, nor explain to the jury the value at which it should be estimated. The non-medical Coroner knew not the error or truth of the opinion, on the blackening of steel by this preparation of arsenic."

"In Liverpool, Mrs. ——— died in child-bed, after an illness of eight days. Instruments had been used to effect delivery. An inquest was held on the body, and a verdict of manslaughter was recorded against a young gentleman (a medical assistant), who was publicly sent to the county jail at Lancaster, pinioned to a common felon. The evidence implicating this young gentleman consisted in statements, showing that he was present from an early period of the labour, and when instruments were used by others, that he interfered too much, which evidence was only hearsay, related to another by the suffering lady herself; and that he was seen in an ante-room with instruments in his hand, when he replied in the affirmative to one asking if he was going to use them. With this evidence, defective, presumptuous, unsatisfactory, and of secondary consequence were the Coroner and his legal officer content, and, in consequence of their incompetency from want of medical knowledge, they could neither assist the jury, nor promote the investigation, by ascertaining the nature and extent of the interference and the part he interfered with, which were the head and front of his offence, and what was the consequence of that interference, and what use he made of the instruments. Highly important and absolutely necessary as these points of the investigation were, the Coroner,

through ignorance of medical science, could neither question nor appreciate, though witnesses were present from whom the inquiry might have been made. Upon this evidence, defective, and miserably managed, was this young gentleman singled out as the only victim, and he appears to have been made the principal in the first degree of guilt, which was more strange and surprising than all other errors. He was subsequently discharged, on the surrender of his bail, without redress."

"I have," says Mr. Rogerson, in conclusion, "briefly and impartially pointed out the principal knowledge necessary for efficiently conducting the Court of the Coroner, which is in its nature essentially medical. The requisite legal information is soon gained by any rational individual, for the examinations seek into MATTERS OF FACT RATHER THAN OF LAW. The Court is not one for the decision and examination of points of law, and for the award of punishment, but of preliminary investigation and inquiry on violent, sudden, and unnatural deaths, and deaths in prison, and their causes. The requisite medical information, then, must be profound, and can only be learnt by years of study and practice."

The pamphlet is published by Messrs. Longman and Co. Let the object to which it is devoted be everywhere pursued in the new corporations.

THE LANCET.

London, Saturday, March 5, 1836.

A CONDENSED report of the proceedings which took place in the House of Commons on Tuesday evening last, will be read with satisfaction by our professional brethren throughout the empire. At last the Legislature is evidently disposed to do justice to the claims of medical practitioners. As some time must elapse before the bill can go into Committee, petitions should still be forwarded in support of the measure, and we again take the opportunity of hinting to some gentlemen who have been meritoriously active in this struggle, that a petition having six signatures is just as efficacious as one containing six hundred. Attaching seven or eight hundred names to a

petition is, comparatively speaking, a much less application of that force which the general body of the profession is capable of using in the consideration of this question.

It should be observed that the Bill which is now about to be introduced into the House, is not, as many persons seem to imagine, a "CORONERS' BILL," but, simply, a "MEDICAL WITNESSES BILL," having no reference whatever to the Coroner's inquest, excepting that of providing the best medical testimony for the guidance of the coroner and jury, and of providing also an approach to an adequate recompense for the services of those medical practitioners who may be summoned to attend the inquiry. So far as the introducer of the Bill is concerned, he will steadily and strenuously oppose the introduction of any clause, the object of which is opposed to these two paramount provisions. The introduction of any other matter might present an insurmountable obstacle to the passing of the Bill, on two occasions. The attempt to constitute the Coroner's an open Court, was fatal to two Bills which had passed the House of Commons in the years 1833 and 34. However desirable, therefore, such an enactment might be under any other circumstances, it would be absurd, and even mischievous, to make any proposition of a similar kind in a similar measure. The medical question stands apart from every other, in this instance, as involving the capabilities and efficiencies of all the powers and privileges of the institution. In cases where the cause of death is involved in mystery, then it is that the medical witness, relieves, by his testimony, the coroner and jury from a net-work of endless difficulties. On the other hand, in ordinary cases, the attendance of a medical practitioner at inquests is frequently unnecessary. Still, he is summoned, and often, as we have a thousand times contended, wantonly summoned, to a place which is situated at several miles distance from his residence, where, after having waited during many hours for

the appearance of Mr. Coroner, he is ultimately dismissed without a further attendance, because he has no evidence to communicate to the Court. If the body of a person be cut into two parts by the wheel of a waggon,—if a labourer be crushed to atoms by a thrashing machine,—or if the head of a workman be blown off by the explosion of a powder-mill, or he be plunged into a flood by the wheel of a water-mill, a medical practitioner is always one of the witnesses summoned, although the cause of death is perfectly obvious, and cannot, in either case, be misunderstood, even by a child. Medical gentlemen have much to complain of in these respects, and it is to be hoped that a brighter prospect is before them for the future. When provision is made by law for paying the surgeon for his attendance at inquests, this practice of issuing the summonses wantonly, will, doubtless, be discontinued. On the other hand, when the circumstances of the case demand the production of efficient medical testimony to aid the coroner and jury in conducting the investigation to a rational conclusion, then the law will empower the court to procure medical evidence of a perfectly satisfactory description.

The justice of the proposition for reimbursing medical witnesses, for the devotion of their time to the purposes of coroners' inquisitions, is admitted by the members of the House of Commons, with very few exceptions. Amongst the dissentients stands, first and foremost, the hon. Member for Cirencester, Mr. Cripps. Yet a writer, whose low-minded malignity is only equalled by his stupidity, has asserted that "the MEMBER for FINSBURY has treated Mr. Cripps shabbily, by taking the cause of 'the medical men out of that gentleman's hands.'" What is the answer to this warrantable assertion, made by a person whose systematic anonymous attacks against the respectability and interests of the general practitioners of this kingdom, have rendered him, with that body, an object of

scorn, derision, and contempt. What, we repeat, is the answer to our inquiries and false imputation? That the Coroners Bill of Mr. CRIPPS passed the House of Commons, without containing any medical clause, in the year 1833. That the Bill was introduced and read a second time, without any medical clause, in 1834. That a medical clause was at length introduced in a Committee of the House, after twenty articles at least had appeared upon the subject in this Journal, and after we had succeeded in causing numerous petitions to be presented to the House on this subject, and in 1835 the Bill was introduced into Parliament with the identical clause which the Committee had sanctioned in the previous session. We have called it a "medical clause," but did even that clause provide for the payment of medical witnesses at inquests? Why, the fact is directly the reverse. Here is the section itself, printed *verbatim et literatim*, as it was introduced into the bill of last session:—

"And whereas, at the taking of inquisitions on the bodies of persons lying dead, it is frequently necessary, for the more satisfactory explanation of the cause of the death of such persons, that a post-mortem examination of such bodies, or of some part thereof, should be made by some surgeon or other person of the medical profession, and his evidence given on such examination; and whereas there is at present no remuneration provided for such surgeon or other person, whereby great difficulty exists in procuring such post-mortem examination to be made; be it therefore enacted, that in every case where the assistance of any such surgeon or other person, for the purpose of such post-mortem examination and his evidence thereon, shall be thought necessary, and be required by the coroner and jury, the constable of the parish or place in which such inquest shall be held, shall, on the direction of the coroner, pay to every such person, if he shall require it, a reasonable fee (such fee in no case to exceed the sum of one pound), before he shall be called upon to give his evidence; and such sum, so paid by the said constable, shall be reimbursed to him out of the funds provided for the relief of the poor of such parish; provided always that such remuneration shall not be given to any such person when he shall be called upon only to give evidence as the medical attendant of such de-

ceased person during his lifetime, or at the time of his death."

What is to be thought of that medical writer who can be guilty of the infamy and falsehood of alleging that the enactment of such a provision as this would provide for the payment of medical witnesses at Coroners' inquests? Yet this was the clause that was introduced into the Bill of last session,—a section of the measure, be it observed, which its author then stated, and still states, was "forced upon him;" and the same gentleman informed us in the House of Commons, on Tuesday evening last, before the motion for introducing the Medical Witnesses Bill was brought forward, "that he should oppose that motion," and yet, "the Member for Finsbury has behaved 'shabbily towards Mr. CRIPPS, by taking the 'conduct of the medical question contained in the Coroners Bill, out of his hands!'"

The reader is requested to examine the stipulations of the section which we have just quoted, and then judge whether such provisions could give, or ought to give, satisfaction to the members of the medical profession. The medical witness was in no case to receive more than one pound, *even if he instituted a post-mortem examination*—and where the medical practitioner was summoned before the coroner as the medical attendant during the lifetime of the deceased; in other words, when he was actually called before the inquest as a medical witness, without instituting a post-mortem examination, it was expressly enjoined, in the concluding lines of the foregoing clause, that the remuneration of one pound should *not* be awarded to the practitioner. Yet this was the species of enactment which was to protect the interests of the general practitioner! In sooth, it is just that description of injury and insult, under the name of protection, which the SLANDERER employed by the corruptionists and bats, would be glad to see enforced against every respectable surgeon and apothecary in this country.

With reference to the very short Bill which is to be brought before the House, it may be necessary to remark, that from what the profession has lately seen of the conduct of the coroners at inquests which have been held on the bodies of persons who have been supposed to die from the poisonous effects of quack medicines, it has become absolutely necessary that the power and ascendancy of the science of medicine should be instantly acknowledged by the non-medical officers who preside in those courts. Under existing circumstances the public cannot hope for protection from any other shield or authority. If the chief officers of those courts were qualified to discharge the duties in consequence of having received an efficient medical education, then it might happen that the collateral aids of professional testimony might not be so essential in promoting the ends of justice; but it has lately been seen that in some instances the infamous quacks have either awed or seduced the coroners into the adoption of a pusillanimous course of conduct, which has had a direct tendency to perpetuate the pestilence which is now so rapidly selecting its victims from the ranks of all classes of society. The juries, however, acting upon the sturdy principles of common sense, have faithfully and nobly discharged their duty to the community, and we doubt not, on the next occasion, when an inquest is held on one of the poisoned, that the chief culprit will be made to suffer, at one blow, both for his boundless avarice and his numerous crimes.

PURGATIVE SEEDS.—At the last meeting of the *Medico-Botanical Society*, Dr. SIGMOND made some remarks on the seeds of the *satropha curcas*, samples of which, in their capsules, had been sent to the Society by Mr. MONTGOMERY MARTIN. These seeds, when ripe and fresh, after being slightly roasted, and infused in spiced wine in doses of two or three, act as gentle evacuants of the bowels; in larger doses they are strong purgatives, and in still larger they are actively poisonous. The

croton oil acts in a similar way, and two or three drachms, added to a dose of castor oil, increase its purgative effect. It has also been recommended as an external application in some cutaneous diseases, particularly in itch and herpetic eruptions; and also in common rheumatism, and, taken internally, it has been found beneficial in dropsy, apoplexy, and obstinate constipation. Some experiments made by ORTALA to prove the poisonous effects of the seeds were detailed. The effects seem to depend on the violent inflammation produced, and the sympathetic action of the nervous system. The poisonous effects are more strongly marked when it is introduced into the stomach than when applied to the cellular tissue. It was supposed, by CAVENTON who performed some experiments on these seeds, that the oil obtained from them was in every way similar to the croton oil imported from India. The properties of the two oils are, however, very distinct, though their medicinal effects may, in general respects, agree. Dr. SIGMOND thought it possible that the seeds of the *satropha curcas* and the croton tiglium were both employed in the preparation of the croton oil, and that this fact might account in some measure for the great variation in strength of that medicinal agent.

ACCUMULATIONS IN THE COLON?—At the *London Medical Society*, on Monday night last, Mr. ROBERTS detailed a case which he judged worthy of attention, because similar cases had not been recorded. It was one of loss of power in the lower extremities, but not amounting to perfect paralysis. The patient, a coachman, sixty-seven years of age, had lived a regular life, his constitution was good, and the excretions and secretions were well performed, at least apparently so, the derangement of any function not being sufficient to admit of detection. In the calves of the legs there was, for some days, great pain, increased by exertion, but not by pressure; and this pain was followed by a numbness, which was not always constant. His rest was greatly disturbed, and any attempt at walking, after a few paces were accomplished, was followed by total inability to move further. Mr. Roberts was at a loss what name to give to the disease, unless that of "debility," or what to prescribe; but acting on what he considered to be the safest plan, he ordered half a grain of the sulphate of iron, gradually increasing the dose, and combining quinine with it. To his surprise a gradual improvement was brought about, first in one leg, then in the other, and in the space of three weeks the man was completely well. An opposite treatment, Mr. R. believed, would have led to a complete

paralysis of the limbs.—Mr. MERION, in alluding to the case, considered the distention in the nervous energy to have been dependent on an accumulation in the colon, from chronic inflammation, in which state, although daily evacuations followed, still an accumulation was going on, producing, through pressure, the partial paralysis of the nerves supplying the inferior extremities. The therapeutic action of the medicine prescribed, he thought, justified this view.—Mr. ROBERTS strongly objected to this supposition. A loaded state of the colon would have been directly manifested had it existed. Moreover, no increased discharge from the bowels, either before or after he was consulted, had occurred.—Mr. MOORE related the case of a lady who had experienced excessive cramps in the legs, and who had taken mercurials and other medicines, aperients, &c., without benefit, and who, on going into the country, and falling under the hands of a physician who had kept an eye on the state of the colon in particular, was ordered three grains of the sulphate of iron, with one drachm of the carbonate of magnesia, twice a day, when large quantities of scybala were dislodged, and the cramps and other symptoms immediately abated, the lady fully recovering.—Mr. BRYANT, in the course of the evening, remarked, that he had invariably found, in post-mortem inspections, a ramollissement of the spinal marrow to be the consequence of idiopathic paraplegia.

The Society's Anniversary Dinner is fixed for the 8th of March, when Dr. Blicke will deliver the oration.

MR. OSBORN'S EXPERIMENT ON BLOOD.

To the Editor.—Sir: Allow me to express my surprise at the manner in which "W. C., of Brompton-square," has criticised my statement on the detection of tar in the blood. Had he repeated the experiment, he would have been able to form a much more correct opinion of the process as well as of the substance obtained. Of chemistry, W. C. himself, notwithstanding his strictures, appears to be very ignorant, or he would have known from experience, that in all chemical processes, when a strong heat is required, it is necessary to use a metallic or an earthenware retort, and not glass. I beg to inform him that I was not analyzing the blood, as he appears to have supposed, but experimenting on that fluid, and consequently had a different object in view. "W. C." appears anxious to know on what the tar floats after the evaporation of the spirit. Why, on the surface of the water, of course. With regard to the chalk, which he thinks I was too liberal with, he could not possibly have

known the quantity required. I am well aware that I used more than was sufficient to decompose the acid, and should I ever repeat the experiment, I should rather increase than diminish the quantity, which I know, from experience, it is necessary to do. I am sorry that "W. C." has wasted his time in attempting to decide on what he evidently does not understand. And as he has been so bold as to assert that my experiment was not based on a scientific principle, perhaps, after he has taken the trouble (if he be able to perform the experiment and investigate the result), he will have the goodness to state it briefly to the public, and add his name to the account. I remain, Sir, your most obedient servant,

HENRY OSBORN,
Southampton, Feb. 29, 1836.

PREJUDICE VERSUS SCIENCE.

To the Editor.—Sir: The medical profession have universally expressed their surprise that Drs. Ritchie and Webster should not have been admitted as candidates for Professorships in King's College, Strand, in consequence of their being Dissenters. It may be interesting to many of your numerous readers to know that this *exclusive spirit* had its wicked operation on a former memorable occasion. Mr. KEIRNAN, whose anatomical and pathological knowledge especially qualified him to fill the pathological chair in any University, was rejected by the Council of King's College, on the plea of his being a Dissenter! A beautiful collection of Mr. Keirnan's preparations of the liver was presented by him to the museum of the King's College, but even these unique specimens of art and science had no influence on the bigots. I am, Sir, your sincere admirer, and humble servant,

A LATE PUPIL OF THE COLLEGE.

NORTH-LONDON HOSPITAL.

OSTEO-SARCOMA OF THE JAW.—REMOVAL OF THE SUPERIOR MAXILLARY AND MALAR BONES.

ANN STRUTHER, aged 21, was admitted, February 24, under the care of Mr. LISTON. About four years ago she was very much annoyed with pain in the left side of the head and face, attended occasionally with swelling, which symptoms at the time were attributed to cold. Pain in the teeth of the left superior maxilla supervened, and a tumour appeared on the outer surface of the gum. Three teeth were extracted, with the hope of giving relief, but the swelling afterwards rapidly increased. When about the size of the end of the thumb, it was removed

by the knife. This was done about a month after the first operation, and the patient was now, however, much better, and continued to grow for about three months, at the end of which time she was more submitted to a very severe operation, by which the alveolar process of the superior maxillary bone, and a portion of the tumour, were removed; she stated that there was hæmorrhage for three days after the operation, but that, nevertheless, she was out of bed, and the wound healed at the end of a week. Two or three weeks after this operation the tumour again appeared, and it has continued to increase in size up to the present time. When it was last removed, it was of about the size of a hen's egg. It is now as large as a moderately-sized cocoa-nut, causing great deformity. The mouth is drawn on one side, and the vision of the left eye is partly impeded. She complains of very little pain, and her general health is very good; the swelling is of a very firm consistence, and appears to involve the whole of the superior maxilla; internally it occupies the whole of the palate, but is unattached on the right side; a probe can be passed under it for some distance. It extends backwards as far as the finger can reach, and projects over the velum, so as to conceal a great part of it. The patient came up to town with the intention of having the tumour removed by Mr. LISTON, who accordingly, on Saturday the 27th of Feb., performed the operation.

After removing the central incisor of the right side, the surgeon commenced an incision a little below the inner angle of the eye, and carried it obliquely under the corresponding ala of the nose, so as to detach its cartilage from the bone, then through the lip, into the mouth, in the mesial line. He next made an incision from the prominence of the cheek to the angle of the lip. The flap thus formed was then reflected upwards. The tumour was now so far exposed as to be ascertained to extend considerably backwards, and the operator found it necessary to make another incision in the line of the zygomatic arch, so as to fall nearly at right angles on the outer perpendicular one; this exposed the whole extent of the tumour. With the well-adapted forceps introduced by Mr. LISTON, the nasal process of the superior maxilla was divided. The operator next cut through the zygomatic arch, near the auricle, and then through the malar bone, at the transverse facial suture, into the spheno-maxillary fissure; the diseased maxilla was separated with great facility from its fellow of the opposite side, by strong scissors, leaving the palate entire, and untouched. The diseased mass was now readily removed, involving the whole of the superior maxillary bone, and the whole of the malar. A large artery, which was bleeding very freely (probably

from the maxillary), was immediately secured by the application of the ligature. The bone of the lip was brought into its natural position, and the wound was closed. Two weeks proceeding occupied about convalescence. The tumour is of a firm cartilaginous nature, interspersed with spots of bone, and perfectly entire; not the least portion of diseased structure can possibly have been left behind.

Mr. LISTON preferred using the forceps in this case, as he thought the employment of the saw, or the mallet and chisel, would have jarred the parts, and been productive of much more suffering to the patient. The operation might have been as quickly performed with those instruments as with the forceps.

March 2. The patient is doing exceedingly well; the sutures were removed on Monday.

This operation is worthy of record, both from the facility and the celerity with which it was performed. The case altogether possesses much interest for medical men, and any gentleman who wishes to inspect it will find every facility afforded him for that purpose, should he pay a visit to the hospital.

PSORIASIS.

William Snook, ætat. 22, a footman in a gentleman's family, admitted December 30, 1835, under the care of Dr. ELLIOTSON. He has, until within the last six or eight months, enjoyed good health, when (May) he became slightly indisposed, and there appeared a redness of the skin, affecting the thighs and posterior portion of the knee joints, filling up the popliteal spaces. This continued for two or three days, when a scalliness was first perceived, to which there was quickly superadded painful fissures or rhagades, from which a serous fluid of an acrid nature was continually exhaled.

He was treated for some time by a general practitioner, who prescribed the decoction of dulcamara and blue pill twice a day. Copious pyalism was by this means induced, but the disease nevertheless increased in severity, and about a fortnight or three weeks since he gradually lost all sensation and motion in the inferior extremities, and perceived some numbness in the arms and hands, without, however, affecting volition. Speech became affected, and he hesitated considerably; the mouth being also drawn upwards and to the left side. These symptoms, however, gradually diminished in severity up to the period of his admission into the hospital.

At the present period he hesitates considerably in speaking, is rather deaf, and walks with considerable difficulty, the legs still continuing stiff and heavy. There exists, also, pain and heaviness of head, with occasional dimness of sight and

med. The whole political region of the chest, by a scaly eruption of an intense brown, not elevated above the surface, and not interrupted by deep fissures, which occasionally bleed, still attended with considerable inflammation; bowels open; tongue furred and moist; urine natural; pulse 92, soft, and rather labouring. Mittantur sumptibus $\mathfrak{z}\mathfrak{x}$. D. M.

Jan. 1. 1836. Symptoms not relieved; pain of right side; bowels confined; pulse 10, with the same characters as yesterday. Mittantur sanguis ad $\mathfrak{z}\mathfrak{x}$.—Haustus Sennæ Compos. statim.

5. Continues much the same; the pain of chest, however, being much increased on coughing or taking a deep inspiration. Hirudines decem later, dext. applicatur.

9. Somewhat better, a vesicular eruption of an eczematous character appearing on the lips and chin; pulse 90, soft. *Pilul. Hydrargyri* grana quinque bis die.

13. Eczematous eruption desquamating; mouth not yet affected; pulse 96, and full; tongue furred. Detrahatur sanguis ad $\mathfrak{z}\mathfrak{x}\mathfrak{i}\mathfrak{j}$. Auge pilulam Hydrargyri ad grana decem, bis in die.

22. Pain of head, and other symptoms somewhat increased; mouth not affected; pulse 96, full, and hard; psoriasis hot, red, and very irritable; tongue dry and furred; urine high-coloured and scanty. Venesectio ad $\mathfrak{z}\mathfrak{x}\mathfrak{i}\mathfrak{j}$. *Pilule Hydrargyri* gr. x, ter quotidie sumat.

28. Pain of head; giddiness and stupidity increased; eruption at the bend of knee, hot, red, and exceedingly painful, and dividing, forming rhagades whenever the foot is extended; an abundant secretion of acrid serum excoriating the parts on which it runs. Asperguntur partes affectæ pulvere calamine; fiatque venesectio e brachio ad $\mathfrak{z}\mathfrak{x}\mathfrak{i}\mathfrak{j}$. Sumat pilulam Hydrargyri 6tis horis.

Feb. 1. Mouth still unaffected; eruption round the mouth nearly gone; psoriatic eruption less painful and inflamed; pain of head, giddiness, &c., entirely gone; the blood slightly buffed, not cupped.

8. Gradually improving; some tightness across the chest, and cough, he having contracted a slight cold.

13. Pain in the chest continues, together with the cough, with little irritability of stomach; bowels open; pulse full. Venesectio ad $\mathfrak{z}\mathfrak{x}\mathfrak{i}\mathfrak{j}$. Sumatur *Acidi Hydrocyanici* formulam Scheeli $\mathfrak{z}\mathfrak{j}$, ex *Aqua Mentha Piperita*, f. $\mathfrak{z}\mathfrak{i}\mathfrak{s}\mathfrak{s}$ ter quotidie.

From this period he gradually improved, the general and local symptoms diminishing, and he was presented cured on Tuesday the 19th.

PHAGEDENA OF THE PENIS.—E. B., aged 17, was admitted on the 21st, under the care of Mr. LITTLE, three weeks back a sore appeared near the orifice of the urethra. It continued to enlarge very rapidly. The ap-

pearance first made was the diffused sub-stance of meat, then the carrot pencil, and afterwards a solution of sulphate of copper and solution of turpentine. He has not taken medicine for the last ten months, when his mouth was made sore for some acute inflammation. Hemorrhage from the ulcer commenced a fortnight ago, and has recurred daily since, increasing in its amount and duration so as to blanch him in appearance. Bowels open; pulse 132, small; rests ill. He came to the hospital on account of hemorrhage; he has not suffered from that symptom since his admission. A drachm of the solution of muriate of morphia was given him. The next day the sore was touched freely with nitric acid.

15. The nitric acid has been three times applied since the last report; warm-baths and full diet; nitric acid again applied. Paraphymosis, which had existed, was divided. A pint of decoction of sarasparilla to be taken daily.

21. Nitric acid again applied. The sore looks much healthier.

26. A lotion with four grains of the nitrate of silver to $\mathfrak{z}\mathfrak{j}$ of water applied.

3. Solution of the sulphate of zinc to be applied.

19. Ulceration of the prepuce much better. Great oedema of the prepuce. To foment it.

21. Made an out patient, being nearly well.

CORRESPONDENTS.

THE session of Parliament having commenced, it is earnestly requested that all communications to Mr. WALKER may be addressed to him at his residence, 35, BEDFORD SQUARE.

MR. FERRALL.—With reference to those concluding remarks of "OBSERVATOR" in his communication in THE LANCET of Feb. 20th, which relate to Mr. Ferrall, we feel bound to say that their tendency escaped our notice. In our previous number we did not merely state that, "the authenticity of the petition from the 'Sisters of Charity' had been denied," as the impression on our mind was, that no such petition had been presented at all. We are now authorized to say that no petition was presented on behalf of Mr. Ferrall from that or any other quarter, and that his only communication with Government on the subject, was his own letter to the Chief Secretary, stating, his having filled the office of house-surgeon to the Richmond Hospital for nearly five years, &c.; and this communication was forwarded by a member of the Government,

To the Editor.—Sir, The candid and direct system which has hitherto kept your valuable journal in the highest esteem with the "liberal world," assures me this letter will be published. The last number of *THE LANCET* contained a paragraph stating it to be Dr. Cummin's intention to resign his chair in this school "in deference to the exasperated feelings of the students," which I can faithfully assert was read with surprise and indignation by every one of them, and considered to be equally malicious as false, on the part of the correspondent. Such rumour has not existed, the pupils being satisfied that Dr. C. had no participation in the scurrilous and prejudiced account of the meeting at the *Crown-and-Anchor*, given in the *Medical Gazette*. I am, Sir, with every respect,

A SENIOR STUDENT IN THE
ALDERSGATE MEDICAL SCHOOL.
Reading-room, March 2nd, 1836.

To the Editor.—Sir: Between the period of Mr. Smith's rejection and the meeting at the *Crown-and-Anchor*, I had occasion to call on Dr. Cummin, at his lodgings. The conversation turned on this point, and Dr. C. mentioned that he knew Mr. Smith, and that he considered him to be a clever and well-informed young man. Of course, Sir, it is impossible that Dr. C. should have any connection with the "*Gazette*," for I hope that no one who is a member of our profession could allow another to remain under the stigma of ignorance, when he knew or believed to the contrary, and had so ready a means of stating his knowledge of that fact in print. Your obedient servant,

March 1st.

C. S.

Mr. W. F. SHORBRIDGE has addressed a letter to us in which he states that the late protest from *Guy's Hospital* in favour of the Apothecaries' Hall, was not "a hole-and-corner affair, being done in the face of every one belonging to the hospital." He says that "Messrs. Mugg and Bent" (Mr. Mugg's name was misprinted Muggand in a late *LANCET*) "could not, either with or without favour at court, have passed the Hall, because the former is not out of his apprenticeship, and the latter did not attend the hospital until last year." Our correspondent adds, "that Messrs. M. and B. did not induce the junior pupils to sign the protest." The "fact" which Mr. S. quotes respecting the *Crown-and-Anchor* meeting is certainly not a "fact." We would readily have given insertion to the whole of our correspondent's letter, had we not been enabled in this brief space to present a statement of all the facts which he avouches.

Mr. JOHN A. LUSH, of the Aldersgate-street School, assures us that the feelings of the students of that school "have not been

affected" by Dr. W. Cummin. Mr. Lush, however, having "the assertions of three of our correspondents" supported by an anonymous individual in a periodical so extensively circulated as *THE LANCET*. Mr. Lush has overlooked the fact that those assertions were not "contradicted" on anonymous authority, but on the expressly declared statements of the gentleman whose declarations were first of all impugned. To him we beg leave to refer our correspondent. Mr. Lush has also suffered the fact to escape his memory, that Dr. W. Cummin is charged with getting his bread by editing an anonymous periodical, whose peculiar claim on its subscribers is founded on its unceasing attempts to destroy the moral character of an avowed writer, by statements which are notoriously false,—a crime which in iniquity and turpitude it would be difficult to surpass.

A COPY of the depositions which were taken at the inquest that was held on the body of Captain MACKENZIE is before us, but these are by far too voluminous for insertion in their present form. A condensed abstract of them, however, is in progress for publication. The prosecution of SALMON is not to be conducted by the parish. The prosecutors, therefore, will be entitled to the gratitude of the entire medical body. The depositions contain many statements of a very interesting character. The disclosure which took place at this inquiry, is a compound of impudence, folly, and infamy, almost without a parallel in the annals of quackery.

Some resolutions having been forwarded to us relative to the contents of a note which appeared in the last *LANCET* headed "Gower-street," we may observe that it has since been explained that it was dictated under an erroneous impression, and that the services of no teacher can be more highly valued than are those of the gentleman whose absence from the usual scene of his duties was made the subject of comment. It could not have been known to the writers of the note in question, that most of the hours which are spent out of the dissecting-room, are devoted to a practical examination of the more advanced students,—not an examination consisting of the rote questions of our books, but founded upon a thoroughly scientific acquaintance with the structure of the human body.

Letters from Mr. Denham, R. E. L., Mr. L. (of T.), An Assistant Chemist, J. B.—The letter of a M.R.C.S. will probably appear.

C. The second, also, of the two papers from the North shall appear. So shall Mr. Schnid's letter.—A Student, T. C., Dublin, intimates that he can speak for the truth of his statements. Will he give us by authenticating them, privately, with his name and address. They cannot of course appear until we are satisfied on this point.

THE LANCET.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Assistant in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XV.

RAMOLLISSMENT OF THE NERVOUS CENTRES.

(Continued from p. 891.)

Ramollissement with Contraction of Limbs.

As one of the most frequent modifications of motion produced by ramollissement of the brain, we have mentioned contraction of one or more limbs or muscles; this contraction consists in a flexion of the limb, joined to rigidity, and presents the same differences as paralysis, with respect to its degree, mode of appearance, march, and seat. When developed in the commencement of the disease, contraction is an excellent symptom; indeed, one of the best signs by which we may diagnose ramollissement. It certainly does frequently exist as a symptom of the disease in question, and M. LALLEMAND has insisted with a good deal of energy and reason on its value as a pathognomonic sign. There is a good deal of truth in this; contraction is a palpable symptom when it occurs in an early stage; but we must allow, on the other hand, that several cases do exist where this symptom is absent, and that if we were to connect ramollissement and contraction too strictly together, we should incur the danger of committing a gross error. Some authors, in reply to this our last observation, will tell you, that if cases of ramollis-

sement without contraction have been observed, it is because the cases were not studied with sufficient attention or minuteness; the observations imperfectly or carelessly reported. This may be true for a certain number of cases, because when an appeal is made against accuracy and fidelity, one can only answer for his own observations; but we can affirm, that we have seen individuals in whom ramollissement was announced from the very commencement of the symptoms, by paralysis alone, without any contraction of the limbs or muscles: of this we are perfectly sure. The nature of the disease was determined after death by inspection of the body, and during life the functional derangements were noted down with accuracy and care. If such a symptom as contraction existed at any period of the malady, it could not have escaped our notice, especially as we looked for it in all the cases of ramollissement that fell under our own observation. You will find several cases demonstrating the truth of what we have just advanced, in the fifth volume of the *Clinique Médicale*, and in the work of M. ROSTAN on softening of the brain.

However, whenever contraction does exist, we may diagnose the presence of ramollissement with great probability of being right in our judgment, for, although the absence of this symptom, as we have just said, does not prove the absence of softening, yet its presence is a very strong proof of the existence of this lesion in the brain. Like paralysis, the contraction may come on in a gradual manner, and increase slowly, until it terminates in loss of motion, which latter continues until the end of the disease. When it persists for a length of time, the force with which the muscles are flexed is sometimes extraordinary; the fingers are clenched so firmly that it is impossible to open them, and even the nails are driven into the palms of the hand.

When once established, this contraction does not always exist in a permanent manner; it is not unusual to see it disappear for several hours, or even a whole day, and then return with its ancient intensity. During the intervals, the affected muscles either recover their power of motion, or, what is

more common, they remain feeble and benumbed, or more or less paralyzed. Again, we may have cases where the contraction disappears altogether, and is replaced by paralysis, or where these two phenomena alternately assume each the place of the other, as we have already seen paralysis and convulsions alternately attacking the affected limb.

The contraction may appear in a sudden manner; in fact, several cases of ramollissement have commenced by a violent contraction of one or both limbs on one side of the body, and then the symptom becomes peculiarly characteristic of the disease.

Paralysis, direct, and opposite the Lesion.

The progress of the contraction also varies in different cases; sometimes it persists, either gradually increasing, diminishing, or resting stationary; in other cases it may remain only for a few hours, or even minutes, and then be replaced by paralysis; and, once gone, it may either never appear again, or return only at uncertain intervals. We have ourselves witnessed all the different lesions of motion now described; you see that they are numerous; but this is not all; these diversified symptoms may also vary according to the different seats which they occupy; in some cases only a single limb is affected; in others the two limbs on the same side of the body are contracted. Finally, in a certain number of cases, the contraction affects the four limbs at the same time; these different lesions seem to depend on the different seats of ramollissement in the nervous centres; and here an interesting question presents itself,—Do we observe a diversity of symptoms, according as the ramollissement may occupy the anterior portion of the brain, its middle portion, or the posterior lobes? Does softening of the striated bodies manifest itself by peculiar phenomena, which enable us to distinguish it from softening of the thalamus, or of any other part of the brain? This is exactly the same question which we took such pains to resolve when treating of cerebral hemorrhage. It is to be answered in the same manner, and we must refer you to what was said upon that occasion; it were useless to repeat now what has been already said. The paralysis which results as an effect of ramollissement of the nervous centres, generally affects that side of the body which is opposite the injured hemisphere of the brain; this, if you remember, is the same law which governs the loss of motion in cases of apoplexy, where the paralysis is almost universally crossed; however, we find some exceptions to this rule; the paralysis is sometimes direct and not opposite; in some cases ramollissement of the brain, as well as cerebral hemorrhage, gives rise to loss of motion on the same side of the body as the ramollissement. Thus, in

the number of cases which we analyzed in a former lecture, with the object of determining whether the paralysis resulting from disease of the brain is direct or opposite; the two last cases, taken from the thesis of M. CHAMBERYON, were cases of ramollissement of the brain, and not of hemorrhage.

The intensity with which the contraction manifests itself is various, and it may occupy more or less of the four members at the same time. In some cases we see the muscular contraction confined for a length of time to a single finger, or even to a single phalanx of that finger; sometimes it extends to all the fingers of one hand, or to contraction of the fingers we find joined a flexion, more or less permanent, of the fore-arm or the arm; the same remark is applicable to contraction of the lower extremity; one or more toes may be flexed, or the leg forcibly bent upon the thigh.

Ramollissement with Convulsions.

The different forms of lesion affecting motility now described, may present themselves with different degrees of frequency; however, they belong peculiarly to ramollissement of the nervous centres, and when we observe them in any case, we may diagnose that affection with a great certainty of being right.

It is unnecessary, however, to warn you that ramollissement of the brain may be accompanied by certain accidents which are not comprehended under the rules now laid down, and if you were to meet them in practice, you would in all probability be led astray unless acquainted beforehand with these, as it were, anomalous phenomena. Thus some patients are affected with general or partial convulsions, very similar to those we observe in cases of cerebral congestion or meningitis; when partial, they affect the side of the body opposite the softened hemisphere; general convulsions are almost always the effect of a double lesion in the brain. Finally, in a few rare and exceptional cases, the convulsions have been seen to attack the same side of the body as the lesion in the brain.

Ramollissement producing Epilepsy and Tetanus.

Ramollissement of the cerebral hemispheres may sometimes declare itself under the appearance of epilepsy. M. LÉLUT has published an observation of this kind in the *Journal Hebdomadaire*, February 1830; the patient, who had gone to bed in good health, was seized in the night with violent epileptic fits, and soon died; an extensive ramollissement was found occupying the superficial and deep-seated parts of one hemisphere.

Again, in some cases ramollissement produces symptoms of tetanus, either partial or general; but these cases are exceptional.

cases we find mention made of, being the only lesion of motion observed; this also is an exception.

Ramollissement without affecting Motility.

Here are cases where the lesion of motility is unusual, and different from those which commonly attend ramollissement of the nervous centres; in some cases all symptoms of this kind are absent; we observe neither convulsion, nor paralysis, nor contraction; in a word, the patient exhibits no symptom of injured motility. This is the same thing as we occasionally observe with respect to the intelligence, but it is infinitely more rare; the exception, however, does exist. We have seen examples ourselves, and the observations published by other authors prove beyond doubt that ramollissement of the brain may terminate fatally, without having once produced the least modification of motion. These cases are generally seen in persons wasted away by long ill-health, reduced and worn down by some chronic disease, for example, and the ramollissement usually occupies a small portion of the nervous substance. But we must again repeat that they are rare. The number of cases of ramollissement now published is great, very great; perhaps we could collect between two and three hundred cases scattered through different works, yet we only know of six or seven cases in which no lesion of motility has been observed. This is all we have to say in respect of the lesions of motility which accompany ramollissement of the cerebral hemispheres. We shall next speak of lesions of sensibility as symptoms of ramollissement of the cerebral hemispheres.

Lesions of Sensibility

constitute a set of symptoms of some importance in the diagnosis of ramollissement of the cerebral hemispheres. These lesions may have their seat, either in the brain itself, or in some other part of the body.

The first and most remarkable phenomenon to which we would direct your attention, is the headache that accompanies a great number of cases of ramollissement. This symptom, noticed by all writers on cerebral ramollissement, and on which M. ROSKIN insists with considerable force as a sign of the disease in question, is seen in a majority of cases, although we have witnessed a certain number where the headache was completely absent. This modification of the sensibility, produced by softening of the brain, has not always the same seat. In some cases the headache is exactly limited to a point of the head which corresponds with the seat of the disease. The patient, when asked where he suffers, places his finger upon the softened portion of the brain, and indicates that as the point of suffering. There is, in fact, a wonderful coincidence between the pain in the head

and the seat of the ramollissement in the substance of the brain; other patients complain of a vague pain, occupying indistinctly the whole cranium, and which they are unable to localize, otherwise than by saying they have a headache. In other cases, again, the pain is fixed, circumscribed to a small part of the head; but this does not correspond, as in the first set of cases mentioned, with the lesion in the brain; on the contrary, it is situated at a greater or less distance from the softened point. Thus the pain may be confined entirely to the forehead, although the ramollissement is seated in the posterior lobes of the cerebrum, or even in the cerebellum. There are cases where the pain, general and vague in the first instance, becomes limited as the disease advances. Finally, we sometimes see the pain diverging, as it were, from a central point, attacking other parts of the head, and extending even to the neck or thoracic extremities.

The intensity of this headache is very variable; in some cases the cephalalgia is excessively intense, and the patient complains of a lancinating pain which often forces him to scream out from excess of suffering. In other cases the cephalalgia is much more feeble; the patient, perhaps, complains of a weight, of an unpleasant sensation, either confined to one point, or extending to the whole cranium; or the headache is so slight, that unless you ask the patient directly whether he suffers in the head, this symptom may escape your notice altogether. We do not find that it has any peculiar distinguishing character: in some cases the patient describes it as lancinating; in others as a dull and heavy pain; in a word, we find here the same varieties as to character, as we observe in headache arising from any other cause.

This modification of sensibility varies also in relation to the constancy with which it may exist. In several cases the patient complains of his head throughout the whole course of the disease; his headache is constant and never quits him. In other cases the pain, habitually slight, is much aggravated at certain intervals, is renewed under the influence of moral emotions, by febrile reaction, exercise, &c., or we find that the headache returns without our being able to explain the cause of relapse. We call to mind one case in particular, of a curious nature, where the cephalalgia was completely intermittent, and returned at certain fixed periods, and the disease was mistaken for one of intermitting neuralgia.

The duration of this symptom is also various; in many cases it commences with the commencement of the malady, continues through its whole course, and only terminates with death. In other cases the headache disappears in proportion as paralysis advances, and is at last completely removed. Finally, the cephalalgia may vary

according to the period of time at which it commences; thus it may open the scene, and constitute the first symptom of ramollissement, or it may precede all the other phenomena, and exist solely in an isolated manner, for a great or less period before the actual development of the lesion; the duration of this *prodrome* is generally not long; from a few hours to five or six days; but in some cases we have seen it existing as a premonitory symptom for fifteen, twenty, or even thirty days.

Another and the last kind which we shall mention, is that where the commencement of the disease is not attended with any lesion of sensibility. The headache comes on at a later period, when paralysis, or contraction, is already more or less feebly established. However, you must remember that this lesion sometimes does not exist at any period. You may meet with several cases of ramollissement of the brain where it is altogether wanting during the whole course of the disease.

We also have occasion to observe certain lesions of sensibility in other parts that are placed under the dominion of the brain. We shall now examine these, and for the sake of order we shall divide them into three distinct classes. In the *first*, the individual exhibits no modification of sensibility in the integuments of the limb which is contracted or paralyzed. In the *second* class of cases, the sensibility is either diminished or altogether lost. When the patient touches an object, he is not sensible of its contact. If you prick the skin, he does not feel the slightest pain, &c. In the *third* series, the sensibility, far from being diminished, is, on the contrary, exalted.

The diminution or complete abolition of sensibility is chiefly remarked in the integuments of the limb, which is at the same time the seat of a lesion of motility. In most cases the power of motion is not lost until paralysis has already existed, but in others we may observe a numbness of the toes or fingers, a sensation of cold or prickling in those parts long before any characteristic symptom of ramollissement has made its appearance. Paralysis, however, is soon established, and with it comes a complete though gradual destruction of sensibility. In some cases that are rare, the whole skin at uncertain intervals has become more dull, more unimpressionable, than natural, and afterwards recovers its ordinary power of sensation. In the third series of cases above alluded to, when the sensibility is exaggerated, we find pain situated either in the skin alone, or in the subcutaneous tissues. The alteration of cutaneous sensibility exaggerated, we find pain situated either in the skin alone, or in the subcutaneous tissues. The alteration of cutaneous sensibility is generally confined to the paralyzed or contracted limb; the integuments then

become excessively painful, and the touch is sufficient to produce excruciating convulsive motions of the muscles. At other times (but this is much more rare) the exaggeration of cutaneous sensibility extends itself to the whole integuments of the body, and the least contact becomes insupportable. In other cases, the sensibility of the skin, either remaining unaltered, or presenting any one of the modifications just described, the more deep parts become the seat of pain: these deep-seated pains may coexist with paralysis or contraction of the limb. They sometimes are very violent, and give rise to the most horrible cramps, which all our efforts are unable either to remedy or alleviate. These pains may exist habitually, or cease for some time and then return again. They sometimes precede, for a considerable period, all the other symptoms of ramollissement; we should therefore well observe their form, march, and nature, and all the circumstances, however trifling, by which they are accompanied, in order to avoid mistaking them for neuralgia or a rheumatismal affection. Some patients, on the other hand, are free from pain during the whole malady, and they are fortunate indeed, for the sufferings to which many are subject are of the most distressing nature.

What shall we say of the

Lesions Exhibited by the Organs of Sense

In cases of ramollissement of the cerebral hemispheres? The symptoms connected with the organs of sense do not afford any thing very particularly worthy of mention; or all that we might say would be merely a repetition of what has been already explained under the head of hemorrhage; the sight may be either diminished or completely lost; the hearing may undergo the same modifications. In one case, recorded in our *Œuvre*, the patient lost the power of seeing, on the same side as the paralyzed limb.

Lesions of the Digestion, the Circulation, and the Respiration.

Let us now pass to the influence of ramollissement of the cerebral hemispheres on the various acts of nutritive life: here also we have very little to say of importance. The *digestion* is but slightly, if at all, troubled; the tongue remains natural, and the abdomen is not painful or tumid; however, in a few cases, we may observe vomiting, and the bowels are ordinarily a little costive: these, as you see, do not constitute any notable symptoms. The *circulation* does not seem to suffer any great degree of trouble, although here the modifications are better marked. In many cases the pulse remains calm, and does not exceed its normal frequency. In other cases the pulse is evidently accelerated, and then the ramollissement seems to be of an acute nature.

The *respiration* becomes implicated soon or frequently than in any other of the faculties or circulations; in several cases the *aspiration* remains intact. When the ramollissement is formed in a slow and gradual manner, this faculty is not deranged at first in any degree that attracts attention; however, as the disease advances, the functions of the lungs become impeded, then embarrassed and difficult, and the patient at length dies in a kind of asphyxia. If the ramollissement progress very rapidly,—he formed in a sudden and violent manner,—the respiration at once becomes embarrassed, assumes a stertorous character, and it is a matter of the greatest difficulty to distinguish this form of the disease from hemorrhage of the brain; indeed, under certain circumstances, it is actually impossible to say whether a patient suddenly seized with coma and stertorous respiration be not affected with apoplexy, though after death we find nothing but softening of the nervous pulp. This is certain; we have witnessed it more than once, and your future experience will not doubt attest its truth.

Ramollissement Acute.

We have now passed in review the different symptoms which accompany ramollissement of the cerebral hemispheres; but these actual derangements do not always group themselves together in the same manner; hence arise different forms of the same disease, with which we must be acquainted, whose features we must study, to revise our history of ramollissement and remain imperfect and unfaithful. In the *first form* to which we would direct your attention, ramollissement commences and arches with all the characters of an acute disease; there is a sudden loss of consciousness, accompanied by paralysis of the muscles on one side of the body; this case is rare. Ramollissement of the cerebral hemispheres very seldom commences with such violent symptoms, but we have seen examples of this kind, and we were intimately convinced that the patient laboured under an attack of apoplexy. We opened the body after death, and sought in vain for the expected coagulum; on the contrary, we found an extensive softening, without effusion in one of the hemispheres. The loss of consciousness, marking the access of this form, may persist until death, or the coma disappears, but leaves behind it the various signs of intelligence which we have already described at sufficient length.

The *second form* resembles the first in the sudden annihilation of the intellectual faculties, but instead of paralysis affecting one or more limbs, we have contraction; and this latter sign then indicates almost in a certain manner that the disorder is a ramollissement of the cerebral pulp.

In the *third form* also we observe a sud-

den loss of consciousness; but the lesion of motility is neither manifested in paralysis or contraction; we have convulsions: these affect either one side of the body or both. When the convulsions are confined to one half of the body, we may diagnosticate the presence of ramollissement; but when they are general, affecting various muscles on both sides, it is not so easy to discover the real nature of the lesion on which they depend.

In the *fourth form* we do not observe any sudden loss of consciousness: the intellectual faculties remain intact, but the power of motion is either suddenly lost, or modified in various ways already alluded to. These cases are also embarrassing, and require cautious examination. They may be very readily confounded with hemorrhage of the brain, for what is more natural, when you find a patient suddenly deprived of all power over his hand or leg, than to attribute this lesion to the effects of effusion into the cerebral substance?

Ramollissement Chronic.

We now arrive at a *fifth form*, in which ramollissement appears as a chronic disease; here the intellect is preserved for a long period of the disease, and we do not observe any sudden modification of sensibility or motility, the disease, on the contrary, marches gradually, the patient at first finds that the limbs at one side of the body are a little weaker than those at the opposite side; sometimes they are only a little painful, but this feebleness gradually changes into true paralysis, or contraction: these symptoms persist, or become more and more intense, the lesion of the brain now exercises an influence on the economy at large, the respiration is gradually compromised, and the patient dies, at length, either asphyxiated, or worn out by suffering and general weakness. Cases of this kind are much more easy to diagnosticate than those in which the disease commences *brusquely*, and imitates apoplexy. When we find a patient enjoying the full exercise of his intellectual faculties, but in whom the power of motion in one side of the body has been gradually lost, or where the hand and arm have become slowly contracted, we may with some degree of certainty pronounce on the existence of ramollissement, for there is only one other lesion, viz. tubercles, which can imitate this form, and even they perhaps produce their symptoms more by the state of the cerebral pulp round them than from anything else. Thus, if in some cases the diagnosis of ramollissement be easy, there are others where we find much difficulty in distinguishing it from cerebral hemorrhage, from meningitis, or from accidental products in the brain.

Finally, in the *sixth* and last form that we shall notice, the disease is completely

latent. During life the patient does not exhibit any single modification of the intelligence, of the motile power, or of the sensibility, yet after death we find softening of one or more points of the cerebral hemispheres, sometimes existing to a very considerable extent, from the insidious manner in which it marches, and from the complete absence of all symptoms; this form justly merits the name we have given it of "latent ramollissement."

I have now given you a pretty extensive description of the symptoms that accompany ramollissement of the cerebral hemispheres; but I have still a few words to add upon this part of our subject, after which I shall pass to ramollissement of other portions of the nervous centres. The observations which I have just made to you turn upon a certain number of forms into which ramollissement of the cerebral hemispheres may be distinguished, according to the different symptoms which attend and characterize each particular form. I have enumerated six species of ramollissement, founded on the absence or presence of coma, of paralysis, or of convulsive movements. The last form which I named was the *latent*, from the fact of its being announced by no functional lesion whatever, by none of those symptoms which in all the rest lead us to establish the existence of ramollissement of the brain. We also saw how ramollissement of the hemispheres may sometimes present itself under characters so well marked, so prominent and decisive, that we cannot possibly confound it with any other lesion. In some cases, however, we have seen the symptoms of such a nature as to bear a strong analogy to those resulting from cerebral congestion, or even hemorrhage of the brain, while it requires some caution and experience to distinguish a third series from inflammation of the cerebral membranes. We now return to the history of those functional phenomena which manifest themselves during the course of ramollissement of the cerebral hemispheres. A few observations in addition to what we have already said, will complete what we have to say upon the subject.

Order of Succession of the Symptoms of Ramollissement.

The symptoms of softening of the brain do not always present themselves to our notice in the same order of succession, or associated in the same group; hence arise, for the same anatomical lesion, various symptomatic forms that we should be acquainted with. Thus, for example, the disease does not always commence in the same manner or with identical phenomena: in some cases ramollissement of the hemispheres is preceded by a prodrome; this is generally a headache, more or less intense,

of which we spoke in a former part of this lecture. This cephalalgia frequently precedes all the other phenomena, all other lesions of motility or sensibility; it is then a premonitory symptom, or a prodrome, but it does not possess any character by which we can distinguish it from the headache that precedes apoplexy and various other disorders of the nervous centres. In a greater number of cases, the headache commences with the commencement of the disease itself, of which it then constitutes an integral symptom. In some cases we have no cephalalgia, but the ramollissement is preceded by the different accidents (already described in their place) which characterize cerebral congestion. Finally, we may observe some cases where no premonitory symptom exists; the patient is suddenly seized with paralysis, contraction, headache, delirium, or other lesions of sensibility, motility, or intelligence.

Whatever may be the form under which ramollissement of the cerebral hemispheres presents itself, either with a *prodrome*, or suddenly and under an apoplectic form, its duration varies under various circumstances. It is not an easy matter to determine in all cases the exact length of the disease, for we cannot always say at what precise time it has commenced. In some cases, however, the task is more easy, the sudden development of the disease and its rapid course remove all doubts as to its duration. In some of these latter cases, the disease ends fatally in a very short period of time; its march is most rapid, and the individual has ceased to live a few hours after the first symptoms of ramollissement have manifested themselves; other cases, again, terminate still more rapidly. The progress which the disease makes is as rapid as that observed in the most violent forms of cerebral apoplexy. After having lain for one or two hours in a state of paralysis, or complete coma, the patient, who before that period seemed to enjoy perfect health, dies. These examples of ramollissement, destroying in one or two hours, are, however, very rare indeed. In a majority of cases the disease continues for a longer period, and does not terminate fatally before a lapse of ten, twelve, or twenty-four hours, and still more frequently is protracted to so many number of days. In other cases, again, ramollissement assumes the character of a chronic malady; we count its duration, not by hours or days, but by weeks. Thus you will find cases on record where this lesion continues for thirty or forty days; three months; a year. In two cases it has been prolonged to three years. When the ramollissement does not terminate in a fixed period of time, but, as we have just mentioned, continues for many months together we may then conclude that another lesion has been superadded, or coexists with the softening of the cerebral substance, and w

may expect to find an accidental product developed in the brain.

The Termination of Ramollissement

of the cerebral hemispheres is almost constantly fatal. Indeed, it is not easy to find even a single case in which we can say with certainty that any other result took place; however, we must notice the opinion of some authors whose prognosis is more favourable. Thus M. LALLEMAND quotes a certain number of cures. In his treatise on diseases of the brain and its dependencies, you will find it laid down, that a certain number of cases of ramollissement terminate by induration of the cerebral substance; he thinks ramollissement may be converted into the opposite condition of hardening, and that a cure may finally take place in that manner. This is a fact which certainly requires confirmation. When we consider that the symptoms which characterize ramollissement of the brain are so various and uncertain, when we reflect that they may and have often assumed such a form, that it is impossible to distinguish them from meningitis or cerebral apoplexy, we cannot, in the actual state of the science, permit ourselves to conclude with M. LALLEMAND, that a circumscribed induration of one of the hemispheres demonstrates sometimes the existence of previous ramollissement.

A word on the manner in which death takes place in this disease. The fatal termination may simply be the result of functional derangement of the brain produced by ramollissement affecting any one part of its substance. In some cases it requires but a lesion of a small point to determine so great a disturbance of the nervous system as to compromise existence. In other cases the disease progresses until some complication supervenes; we then often find an effusion of blood in the centre of the softened pulp, or an infiltration of purulent matter. Meningitis may come on and hasten death. Finally, when ramollissement assumes a chronic march, inflammations of several organs, and especially of the lungs, or the digestive tube, are added to the original disorder, and close the scene, or the individual dies in a state of general prostration.

*. In addition to the one case which M. ANDRAL gave in a late lecture, in which paralysis existed on the same side of the body as the lesion in the brain, we take the liberty of directing attention to the following cases presenting instances of direct paralysis, they certainly afford every guarantee of authenticity.

In the *Revue Medicale*, 1826, t. 1, p. 137, the case is related of a soldier, 52 years of age, who had a scirrhus of the left hemisphere, with paralysis of the left side of the body.

In the *Revue Medicale*, 1824, t. 1, p. 50,

there is a case, detailed by M. BAYLE, of chronic inflammation of the membranes over the left hemisphere, producing paralysis of movement on the left side.

The same memoir contains an account of seven other observations, extracted by M. BAYLE from different authors, but they do not all present the desirable degree of accuracy.

There is a case of encephaloid tumour in the right hemisphere, in a child twelve years of age, who had epilepsy, and paralysis of the right side, communicated to the "Anatomical Society," and noticed in its bulletin, *Arch. Generales*, 1834, April, p. 602.

A case of pearly tumour situated over the left peduncle of the cerebellum, producing paralysis on the same side as the lesion, was read before the same "Anatomical Society," and noticed in the *Arch. Generales*, 1834, March, p. 449.

Finally, two cases were published by M. DECHAMBRÉ, interne at the *Salpêtrière*, of which an analysis will be found in the *Revue Medicale* for October, 1835, p. 80.

In the *Archives Generales* for June, 1834, p. 239, &c., M. DENOSVILLE mentions that a case of direct paralysis had been observed by M. JORRET.

ON THE EXISTENCE OF
NERVOUS INDUCTION
IN FUNCTIONAL PROCESSES.

By W. F. BOW, M.D., Alarick.

Whether or not nervous influence and electricity, or galvanism, be identical, it is not now my intention to inquire; but there is an important law of electricity, called the Law of Induction, and I am convinced that there is an analogous law of nervous influence, whose operation in the animal frame gives rise to many physiological and pathological phenomena hitherto unexplained. I propose to call this law the "law of nervous induction," and shall attempt to illustrate it by many, of what I conceive are, instances of its operation in health and disease.

"Active electricity existing in any substance, tends always to induce the opposite electrical state in bodies that are near it." In the same manner, if one nerve, or set of nerves, becomes excited, an opposite state is induced in the nerves of a neighbouring set. Take the act of blushing. A moral cause excites the sentient nerves of the cheek, and immediately the nerves which cause contractility in the neighbouring capillaries, assume an opposite state, and permit the distention of those vessels by red blood. Take the movements of the iris.

When the retina becomes excited by light, an opposite state is induced in the nerves, conveying contractile power to the erectile tissue of the iris, which, therefore, in proportion to the excitement of the retina, loses its contractile property, and so becomes distended with blood. Hence its expansion, and the proportionate closure of the pupil. The movements of the iris may be compared to those of a delicate electroscope; or, indeed, this little organ may not inaptly be regarded as a natural and very sensible electrometer, denoting, according to the degree of its expansion, the intensity of excitement of the optic nerve.

To state here what I believe to be the functions of some of the principal nerves, will save much repetition hereafter. The great sympathetic system is composed of two divisions, one of which governs contractility in *all* muscles; the other, by a chemical agency, effects most of the secretions. The nerves of the former division I shall name *contractile*, those of the latter, *chemical*. The *par vagum* are, strictly speaking, chemical nerves, but so connected are they with the spinal accessory, that they may be said to be composed of two divisions. The spinal accessory is a motor nerve; that is, it carries an influence which stimulates to muscular motion. The branches, therefore, or the supposed branches, of the *par vagum*, which carry the influence of this nerve, are motor nerves. The spinal nerves are sentient and motive. The motions effected by the spinal accessory are involuntary; those by the spinal nerves are voluntary; I have, therefore, thought it proper to distinguish the nerves by calling them *motor* and *motive*.

Were it not for the law of nervous induction, the act of filling the stomach with food would be attended, at all times, with a sensation of pain rather than of pleasure; for the muscular fibres of the oesophagus, whose office is merely to transmit the food, would have to do so with a force sufficient to overcome the contractile efforts of the muscles of the stomach, which efforts would be increased in proportion to the quantity introduced. Instead of this, no distending force is required, for there is no resistance offered; the muscular fibres of the stomach become relaxed, and the food falls, as it were, into an empty sac. When the gastric branches of the *par vagum*, viz., those which effect the secretion of the gastric fluid, become excited, some other nerves must assume an opposite condition; for it is, as has already been said, with nervous influence as it is with electricity; an "accumulation of electricity in any one part can be effected in no other way than by withdrawing electricity from another part; nor can electricity be abstracted from the one without being received by another." The excitement of the gastric chemical

nerves, in part, sustained at the expense of the contractile nerves of the stomach; the muscular fibres of the stomach, therefore, become relaxed, and continue so until digestion in the stomach is at an end, when the order of excitement is reversed. The food which stimulated the gastric chemical nerves to activity, by being converted into chyme loses that stimulating property; hence these chemical nerves pass from a positive to a negative state, and, consequently, the contractile nerves pass from a negative to a positive state: the muscular structure thus recovers its tone, and those contractions ensue, by which the chyme is propelled through the pylorus. I am not so minutely acquainted with anatomy as to say where originate the nerves which convey contractile power to the muscular fibres of the pylorus, but I am sure that those nerves cannot proceed from the same ganglions which give off the nerves that convey contractile power to the other muscular fibres of the stomach. If they had the same ganglionic origin, the muscles of the *pylorus* would become relaxed, when the other muscles of the stomach became relaxed, and the food would pass on undigested. Or, supposing the stomach to contain some substance, then, when the muscles of that organ contracted, the pyloric fibres would contract also, and thus force the contained mass through the cardiac orifice.

The contractile nerves of the arteries of the stomach during digestion, assume, also, a negative state, in consequence of the excited state of the nerves sending the gastric fluid; hence those arteries, losing their power of resistance diminished, become distended, and thus present a greater volume of blood to be acted on for the production of the gastric fluid. Digestion could not proceed, were the activity of the *par vagum* not, partly, supported by nervous influence derived from the muscular and arterial structures of the stomach; for the stomach could not then become relaxed to receive the food, nor could the arteries become relaxed so as to be enabled to furnish, in proper quantity, the materials to be acted on by the excited chemical nerves. During digestion, then, so far as the stomach is concerned, we have an example of the operation of the law of nervous induction. We observe results arising from a negative or an inactive state of contractile nerves, induced by a positive or an active state of certain chemical nerves.

In the spleen, during digestion, the reverse is the case; we have there an active state of certain contractile nerve; induced by an inactive state of certain chemical nerves. The spleen is a retaining organ, deriving the nerves which effect this function from the *par vagum*. When the gastric branches, then, of this nerve, become active, the splenic branches necessarily assume an

posite condition; they become inactive. This inactive state of the chemical nerves of the spleen, as necessary to produce an active state of its contractile nerves; and from his operation of the law of induction, arise the changes which are observed to take place in the size of the spleen. It becomes comparatively small during digestion; not, as erroneously conceived, by being compressed by the gorged stomach, but from its vessels gaining an increase of contractile power in consequence of the inactivity of its chemical nerves. The cause of the activity of the gastric branches of the par vagum being removed by the food being converted into chyme, the splenic branches of the par vagum again become active, and thus the condition of the vascular structure of the spleen is again changed, in obedience to the law of induction. That structure becomes relaxed and, therefore, easily distended by blood; hence the spleen again increases in size, as seen as digestion in the stomach is at an end.

It is with the spleen as with every secreting organ. When the chemical nerves of the spleen become active, the nerves which convey contractility to its vascular structure assume an opposite condition, whereby the vessels become relaxed, and they are thus enabled to present to the active nerves a greater volume of blood at the time that blood is required. All glands, during the exercise of their functions, appear swollen, because at such times their bloodvessels, from relaxation, gain an increase in diameter; they therefore, for the time, contain an increased quantity of blood, the onward motion of which is, also, more tardy.

The prevailing doctrine is, that the bloodvessels of a gland become more active when the organ is exercising its function. Thus Dr. Roget, in his "Bridge-water Treatise," says, "the same influence, for example, which increases the power of secretion in any particular gland, is found to increase at the same time the action of those bloodvessels which supply that gland with the materials for secretion." It is utterly impossible that arteries can become more active, and at the same time contain an increased quantity of blood. The truth of this must be plain to every one who will consider for a moment the nature of arterial action,—so plain, indeed, as to create a doubt as to the seriousness of the author of the above quotation, when he penned it.

The nerves furnishing contractility to the pylorus, the ductus choledochus communis, and the spleen, must have the same ganglionic origin; for whilst the splenic branches of the par vagum are inactive, as during digestion in the stomach, the duct becomes constricted, the pylorus is firmly closed, and the spleen is diminished in size. Again, when the splenic branches of the par vagum become active, digestion being end-

ed, the pylorus and the duct become relaxed, the one permitting the chyme to pass, the other permitting the bile to flow; and the spleen itself, from relaxation of its vascular structure, becomes enlarged.

We observe that when the process of digestion is at an end, the nerves which effect the production of the gastric juice, being no longer stimulated, become inactive, giving rise to renewed actions elsewhere. The splenic branches of the par vagum, recovering their power of action, recommence their labours, which contribute to the process of sanguification. As by gastric chemical agency the food is converted into a mass which is incapable of prolonging the excitement of the nerves which produced the conversion; so, by splenic chemical agency, the circulating mass is, by degrees, converted into perfect blood, incapable, at length, of prolonging the excitement of the nerves whose labours contributed to the perfection of the blood. The splenic branches of the par vagum, therefore, in their turn, decrease in activity, inducing thereby a proportionably active state in the nerves which furnish contractility to its vessels, and in the nerves which have a like ganglionic origin; consequently, the spleen, as the blood is perfected, begins to decrease in size; the ductus choledochus becomes again constricted, by which the bile accumulates until again required for admixture with new chyme; and the pylorus is forced into strong contractions, the perception of which gives the sensation of hunger.

It will be observed that I adopt the doctrine of Professors Tiedemann and Gmelin regarding the use of the fluid secreted by the spleen. These gentlemen say that it possesses the property of coagulation, and is mixed with the chyle in the thoracic duct. The blood, therefore, owes much of its coagulating property to this admixture. Bostock says that this hypothesis appears to him to be liable to one fatal objection, namely, that animals have been known to live for an indefinite length of time after the removal of the spleen, without any obvious injury to any of their functions, which could not have been the case if the spleen had been essentially necessary for so important an operation as that of chylification.

Although the spleen, as a secreting organ, is, and must be, necessary to the health of the animal, still the danger to life, on its removal, does not arise from the loss of its product, so much as from the loss of the organ in its capacity of a *directiculum* to nervous influence when digestion is over. This is the most important part of its function; the chief end, apparently, for which it is designed. Were it not for the spleen, the animal would be incommoded by a constant craving for food; and, digestion in the stomach being ended, the whole force of nervous influence which had been employed

in the process, would be thrown upon the system of contractile nerves, giving rise to strong arterial contraction, and, consequently, venous congestion. These are not the fancied effects of the removal of the spleen; their occurrence is confirmed by experiment. The voracity exhibited by animals deprived of the spleen, is so remarkable as to have been noted by almost all who have so experimented. In confirmation of what happens on digestion being ended, from the want of a diverticulum, I shall cite Mr. Dobson:—

"*Experiment 1.*—The spleen of a dog was removed. The animal apparently suffered little pain from the operation. On the following day I gave it a quantity of food; it ate voraciously: for three hours afterwards, no perceptible alteration was produced; but in four hours indications of uneasiness were shown, and the animal became restless, and at last sunk into a torpid state: it was often moaning; the pupils were dilated, the heart labouring, there was frequent micturition, the respiration was exceedingly laborious, and, in short, there was every mark of plethora, or over-fullness of the vascular system. In the course of two hours from this period, the animal began to recover; and in about three hours these symptoms had subsided; considerable languor remained. The animal took a large meal twice or thrice in twenty-four hours, and after each meal precisely similar effects were presented. The animal became more feeble daily. In a month after the operation it died."

All the above symptoms might have been predicted; they all arise from morbidly increased contractility. That of the arterial system, causing venous congestion, is too plain to be disputed; the frequent micturition is testimony sufficient of the state of the bladder. I might here explain the cause of the dog's recovery from the state described, but I think I can do so more clearly, certainly in fewer words, by-and-by.

If the remote cause of the symptoms detailed by Mr. Dobson be the removal of the diverticulum of which I speak, it must follow that if we can render a diverticulum unnecessary, no such symptom need appear. The only way to render a diverticulum unnecessary, is to keep up or prolong the activity of the nerves which secrete the gastric juice, and this, as will be seen by Mr. Dobson's next experiment, can be done by feeding at short intervals:—

"*Experiment 2.*—I next removed the spleen from another dog, but instead of giving full meals, as in the last experiment, I gave a small quantity of food every hour, or every two hours. The animal ate voraciously; no unpleasant symptoms resulted. This plan was pursued for three weeks, when the animal to all appearance was quite well; in fact it became fat; the

artery upon the splenic artery had come within an inch of the abdomen was healed. I then continued giving full meals, twice in twenty-four hours, the same train of symptoms followed each meal, and at the same period, as in the last experiment, though perhaps not so urgent. The animal died in a month from the commencement of this plan of feeding."

There are very many circumstances, independently of facts resting on experiment, which lead to the conclusion that the product of the secreting function of the spleen charges the blood with a great portion of its fibrin. This function of the spleen is foreign to my subject, I shall not, therefore, dilate upon it. I may remark, however, that in certain morbid states of the organ, there is a wonderful deficiency in the coagulating property of the blood, and that, owing to a want of knowledge of this fact, unlooked-for and unhappy results have followed surgical wounds. An interesting case of the kind is to be found in Mr. Wardrop's lectures, published in *THE LANCET* for 1833-34, vol. 1, p. 132; it is as follows:—"I attended a patient, where the introduction of a common seton-needle in the side was followed by a fatal hemorrhage. A gentleman, who had an enlarged spleen, was advised to have a seton introduced in his side, and this was done, in the usual manner, by Sir Astley Cooper. Alarmed by the quantity of blood oozing from the wound, I was sent for to see the patient in the evening of the same day. On withdrawing the cord, pressure, carefully applied, with graduated compresses, did not avail, and the hemorrhage being so profuse as to make it appear probable that some vessels of considerable size had been wounded, I thought it expedient to divide that portion of integument which existed between the two perforations of the seton-needle. Having done this, I found that the blood issued from numerous orifices, and I secured no less than nine vessels with ligatures. Blood continued, however, to ooze from numberless small orifices over the whole surface of the wound, which every mode of treatment usually employed failed in arresting, and the patient died in a few days." Had the fact, that the blood is deficient in coagulating property in some affections of the spleen, been adverted to, the introduction of the seton would not have been advised. In the narration of the above case, the "enlarged spleen" is but incidentally mentioned, the abnormal state of the blood being imputed to peculiarity of constitution. We know, however, that in some chronic affections of the spleen, there is a great tendency to hemorrhage from the stomach and intestines, the discharge not coagulating, but having the appearance of coffee grounds. I know a gentleman who, some years ago, fell from a ladder, and received a bruise on the left side; at present (and

for some time back) the countenance was pale, anxious and uneasy; the region of the spleen, and she has had occasionally, during the last year, sanguineous dejections. A few months ago I had occasion to order a couple of leeches to the nape of the neck of this patient. I advised that they should be applied in the morning, in order that the oozing from the bites might cease before bed-time, for I anticipated, from the disorder of the spleen, that it might be troublesome. They were applied at noon, and the blood continued to ooze until two o'clock next morning, before which time she dared not go to bed.

As enough has been said of the normal operation of the Law of Nervous Induction, physiologically considered, I shall now attempt to give some instances of its abnormal operations, from which the symptoms of disease arise.

A blister being applied to a part of the surface of the body, the sentient nerves there become irritated and excited, and thus an opposite state is induced in the contractile nerves of the neighbouring capillaries. Hence, the power of resistance of these vessels being diminished, they permit of distention by red blood. The irritating cause (the blister) being continued, the relaxation of the vessels increases to such a degree, that lymph oozes from their mouths, which, being confined by the cuticle which it detaches, becomes a barrier to further irritation. In this simple morbid process lies the whole theory of inflammation, that little-understood, though often-handled, subject. The first link in the chain of the diseased action which constitutes inflammation, is a morbid excitement of the sentient nerves of the part; this induces an opposite state of the nerves furnishing contractility to the neighbouring vascular structure; and if the excitement be prolonged, or extended, the opposite condition is also extended to the larger arteries, until, at length, the whole arterial system is involved, and sympathetic fever is established. The most prominent feature of this fever is said to be *excitement* of the sanguiferous system. Excitement indeed! We see vessels furnished with coats for the purpose of confining and forwarding the contents of those vessels; we see them lose the power of resistance, and thus become distended; we see them labour to rid themselves of the distending fluid, by frequent, weak, and unavailing contractions, and yet we name their condition one of "excitement!" If, by "arterial excitement" be meant—"a condition resulting from the loss of power to act forcibly," then the phrase well applied; but there is another to express the condition, and that the curative indication is to reduce the force and frequency of arterial action by blood-letting. If blood-letting in the cure of inflamma-

tion had acted by reducing the force of arterial action, then, as a means of cure, it would never have descended to us; for not one patient could have recovered from the disease, or, more correctly speaking, from the remedy. To be really effective in the cure, venesection must be carried to the extent of impairing, more or less, the energy of the brain. This impairment is denoted by syncope, or a state approaching to it, during which the sentient nerves, which were morbidly active, become passive, and those which furnish contractility to the arteries which were proportionably passive, become active; hence these vessels, having their contractility restored, are enabled to relieve themselves of the distention under which they labour. Instead of reducing the force of arterial action, we increase it; the contractions then become more perfect, and, because more perfect, the contractions become less frequent.

Whatever tends to impair the energy of the brain, and thus, by nervous induction, to increase the contractile power of the arterial system, will be found a means of reducing inflammatory fever. We are told to bleed for the purpose of relaxing the vessels, when it is plain that it is relaxation that ails them. We would bleed in vain, did we not, by so doing, cause a restoration to them of contractile power, in the manner I have attempted to explain.

The remote causes of idiopathic fever, act by impairing the energy of the *brain* and *spinal marrow*, or, in other words, by producing a negative state of those centres, and, of course, of all the nerves proceeding from them. By the law of induction, it necessarily follows that some other nerves—nerves which have not their origin from the brain or the spinal marrow—do assume an opposite, or a positive state. We look now to the sympathetic system, and we find the contractile nerves all positively affected. The chemical nerves of this system are not affected positively. They are negatively affected, not, however, from the same cause which produced the like state of the cerebral and spinal nerves, but because the positive state of the contractile nerves induces a negative state of them. From this morbid distribution of nervous influence, arise all the symptoms which characterize the first stage of fever. From impaired energy of the brain and spinal marrow, we have listlessness, defection of spirits, diminished sensibility, and indisposition to muscular exertion. From increased contractility there is constriction of the arterial system, giving rise to the small and frequent pulse and venous congestion; to paleness of the face and surface of the body; to shrunken features and diminished general bulk. The voluntary muscles become so charged with nervous influence, or contractility, that they, in a manner, change their nature, and be-

come involuntary; hence arise rigors. From the negative state of the chemical nerves of the sympathetic, there is defective secretion throughout the body, undecarbonized blood, and loss of animal heat.

Our best pathologists have it, that the remote causes of fever act by impairing the energy of the *nervous system*. In this there is a fallacy which has proved a heavy drag on pathological research. This error I did not escape when I published on the Nature of Fever, and I therefore endeavoured, with unintentional sophistry, to account for all the symptoms of the first stage, by reference to impaired nervous power generally. Although I then had some notion of the law of induction, I did not see its application sufficiently clear. Blinded by specious authority and early impressions, I argued impaired nervous power from symptoms, nay, signs, of increased contractile power.

Reaction takes place, and the second stage of fever is formed. Let us not take refuge under that miserable philosophy which would have us regard reaction as a specific principle, according to which the first stage becomes the immediate cause of the second. It is evident, that during the negative, or inactive, state of the chemical nerves, the products of secretion throughout the system must become defective in quantity, or in quality, or in both. They must thus act as foreign matter, and become a cause of general irritation. Sooner or later the sentient nerves become alive to this cause of irritation. They become excited, and thus is the order of operation of the law of induction reversed. Contractility, which before superabounded, now becomes deficient; hence the arteries, from a state of constriction, lose their power of resistance, and become distended. This negative state of the contractile nerves now induces a morbidly active state of the chemical nerves; hence the great increase in animal temperature, the highly florid state of the blood, and the acid nature of the secretions.*

With regard to Mr. Dobson's experiments. I said that all the symptoms denoted morbidly-increased contractility, and, consequently, that there must have been a negative state of the chemical nerves. The vitiated products of secretion would then become the irritating cause by which the order of induction was reversed. The animals, however, must have laboured under febrile symptoms until again fed, which, doubtless, was the cause of the "considerable languor" which remained.

I must here conclude. I fear that I have already encroached too largely. If there be

any nervous induction, I have, notwithstanding, simply pointed it out. The subject might fill volumes. If there be not such a law, I have said too much.

Alnwick, Feb. 27, 1836.

HAHNEMANNISM.

To the Editor of THE LANCET.

SIR: Having lately seen some notices of Hahnemann's new doctrine in your valuable Journal, I forward to you the following observations for insertion.

Bold, but inconsiderable and despised, homeopathy originated at the beginning of the present century. Opposed, as its doctrines were, to all hitherto received ideas, it necessarily met with the opposition of the medical world. Hahnemann's proposition of axioms, the blind acceptance of which he required from his followers, could not but be disgusting to the better part of the profession. The proposed abolition of all that had before been held to be true, the mysticisms which obscured the whole system, and the wandering life of the author, were all calculated to keep back disciples. At first, therefore, only such medical men as did not think for themselves could be gained over to the new practice. Peculiar circumstances, however, favoured its extension. Among other causes, perhaps a chief one was, that many were disgusted with Brown's system, which at that time was at its height, and they thus embraced the opposite extreme. But, also, it was a time for *systems*, and, for many purposes, this one answered just as well as any other. I do not wish to say, that all who followed Hahnemann were insincere, or did so blindly, but I am forced to say that, for the greater part, little can be said in their favour.

Every scientific reader of Hahnemann's works, which chiefly treat of chronic diseases, for which he allows three causes only, must perceive, at the first glance, that all he says amounts to assertions merely, for hitherto the proof has been wanting, and the only conclusion to which we can come is, that Hahnemann has rejected all that was received before, without giving us in its place anything but a list of effects of medicines on the healthy. On these the homeopathic practitioner is to found his rules for treating any given case. Of a pathology, he has only given us some fragments. Of a therapy, nothing. The doctrine of diagnosis remains wholly unaltered. The remedies, bleeding and vomiting, are entirely condemned by homeopathy. Although we do not advance in argument the happy effects produced by both of these means ever since medicine became a science, yet

* I speak very gratuitously regarding the acidity of the secretions. I take the hint from M. Donne, *Médecine-Chirurg. Fémin.* Jan. 1826. The acid principle is evolved by positive electricity. Why not by its converse influence?

we must laugh at the ridiculous opinion of those men who discard the system of themselves often has rectified the disease. The Hahnemannians, then, not only oppose medicinal science, but they discard the natural curative process; and yet they all their treatment the most conformable with nature! To try the effects of medicines on the healthy, is a suggestion of Hahnemann's creation. Before his time remedies were observed with regard to the sick only. In some instances their effects, certainly, were known on the healthy, as well, but more from accident than in consequence of investigation. Hahnemann, observing that remedies taken by healthy individuals produced symptoms similar to those diseases against which they were used, founded upon that observation his doctrine of "*similia similibus*," making it a general rule to employ in each diseased state such remedies as would produce the symptoms of a similar malady in the healthy. *A priori*, the correctness of this position cannot be denied. Traces of it we find in the ancients. For instance, it was known that the too free use of quicksilver against lues, produced a disease similar to lues. It was but natural that Hahnemann's system should be very imperfect in the beginning, it being one founded on observation, and consequently requiring much time to perfect it. Whether, however, the conclusions thence drawn be true, or whether the axiom be only true as regards certain remedies, must yet be proved, and only time and many experiments can decide this question either way.

Hahnemann, wishing to observe the effects of different remedies, was obliged to give them pure, *i. e.*, without admixture. And herein consists one of his chief merits with regard to the amelioration of medical science. Before his time remedies were given in such marvellous, and often such absurd compositions, that the effect of each ingredient seldom if ever could be ascertained. This appears the more surprising, as some of the most distinguished practitioners always preferred the simpler forms of prescription. But it seems that the generality of medical men rather copied recipes which were recommended by some authority or other, than thought for themselves. I do not, however, wish to be understood as condemning all compositions, for the value of some has been tested by long experience; but if we consider what ridiculous reasons became the grounds for the adoption of different remedies,—often only the taste, the smell, the colour, or even the form of the drug, we cannot too highly prize the labours of the man who attempted to ascertain the exact operation of each and every remedy to be used. It is certainly a good, to examine the effects of medicines on the healthy; for every attempt to know them is praiseworthy. And homœopathy in this has

certainly done a great deal more than any other system ever did before. To find new specifics is also a merit of Hahnemann and his followers.

We now come to that part of the homœopathic system which may be considered the most absurd, namely,—that the smaller the dose the more intense should be the effect. This assertion is also quite novel, and until Hahnemann has established it on better proofs than have hitherto been afforded, every thinking practitioner must see its feebleness; and, to say the least, it must be confessed that Hahnemann has gone too far in his proposition. There can be, however, no doubt that before Hahnemann, many practitioners have given medicines in unnecessarily large doses, and, in many cases, if they did not observe the desired effect, they continued increasing the doses, not ascribing the failure to their injudicious choice, but to the smallness of the quantity, and so went on, not only failing to cure the evil, but often increasing it, and adding new ones; and though Hahnemann fell from one extreme into the other, we must allow him the merit of being the first to draw attention to the abuse, and of having done all in his power to diminish it. That anything is effected in homœopathic practice with very small doses, may arise from the fact that very powerful remedies, and chiefly in the form of tincture, are used by the disciples, and also that the system of the patient has become very sensible to medicine, in consequence of the exceedingly strict diet enforced.

Of this latter we must say a few words. Much mischief, without doubt, has herein been done by omission. Many medical men have hardly the courage to insist upon a strict diet. Many think it of no importance. The idea of dieting is almost as old as medicine itself, but to abstain from certain spices and certain dishes belongs to Hahnemann, and is new, inasmuch as it regards only the quality and not the quantity. What Hahnemann says with respect to the preservation of health, is hardly worthy of notice, and has as yet only been used to advance some quackery or other. I speak of his hygiene, which recommends the adoption of a certain diet in order to prevent disease.

To show that homœopathy is not without much good, nor its founder without merit, was the object of these remarks, which are chiefly drawn from authorities better informed upon the subject than myself, and I could have wished to see a statement of facts in abler hands than my own. As it is, I hope to be excused. I was merely desirous to show in its true light, a theory which owes its origin to my own country, and which I therefore must be sorry to see condemned without allowing to

934 DOUBLE VISION.—SYMPHILIS.—LIGATURES IN HEMORRHAGE.

which lately came into my possession). It is those reflecting merits which I possess, they certainly possess. I remain, Sir, your very obedient servant,

CHARLES SCHMIDT, M.D.

8, Dover-street, Piccadilly.

March 1, 1836.

DOUBLE VISION.

To the Editor of THE LANCET.

SIR: On reading the account of the case of double vision in your Number of the 27th ult., I have thought it might interest some of your readers, to detail what occurred to myself of a similar nature.

In August 1831, during intensely hot weather, I was travelling alone in the Malle Poste from Bordeaux to Paris (a journey which is not performed in less than sixty hours, including the long stoppages on the road), when, on the second day, I was rather surprised at perceiving the distant rows of trees in double lines, one above the other, which at first I thought was attributable to the badness of the glass of the windows, which were closed, but upon opening them I found to my surprise, that the cause existed in my own vision, and upon trying the effect of opening and closing each eye, I found clearly that both eyes were similarly affected, but the left much more so than the right. It, however, only seemed to attach to distant objects, for persons or cattle near the carriage I saw perfectly distinct as usual. This state continued until I reached Paris, when, thinking it might be occasioned by want of sleep (not being able to repose in a vehicle), I concluded that a day or two's rest would carry it off; but after that period, finding myself unable to look at any thing steadily, and that the left eye had in its white part a yellowish spot as big as a pea, whilst my bowels were much confined, and my head at the crown felt uneasy, and with a kind of strained feeling, I sent for a medical gentleman, whose name I forget, but who immediately wished me to be cupped. To this, having an unconquerable aversion to lose blood, I objected, but permitted him to phlebotomise me *ad libitum*, which he did, and by so doing, unloaded the bowels, and a little relieved the sight; but on my arrival in London a few days afterwards, I found all the symptoms return, and my sight so much affected, that I could not recognise a friend at a few yards distance. Fearing, however, that this evidenced a tendency to apoplexy, I now consented to be cupped, which gave me but temporary relief, and it was not until two months had elapsed, that the affection wore off, which it did gradually, and I have never had a return of it. My eyes are a bluish grey in colour, and my sight has always been remarkably good.

I am inclined to attribute the phenomenon to a profuse loss of blood, occasioned by the excessive heat of the month of France, and to my taking very much exercise, whereas I have always at home been accustomed to much exercise, both equestrian and pedestrian, and nothing deranges me more than confinement in a carriage for any length of time. My living is always temperate. I am, Sir, your obedient servant,

A CONSTANT BUT NON-MEDICAL READER.

Stoke Newington, March 3, 1836.

SYPHILIS.

To the Editor of THE LANCET.

SIR: My attention having been directed to some observations on syphilis, by Mr. Eagle, in THE LANCET, No. 651, I take the liberty of proposing the following questions to him, and to those who advocate the same opinions.

Mr. Eagle assumes, "that many effects imputed to venereal poison are produced by mercury." How is it, then, that of the tens of thousands who are daily taking mercury for other diseases, numbers are not similarly affected?

If the venereal poison be not absorbed, how can the system be contaminated?

What evidence has Mr. Eagle to prove that chancre will produce gonorrhœa, and gonorrhœa chancre? I am aware that the common answer is, that "Two individuals may have connection with the same woman, and the one have chancre and the other clap." But gonorrhœal and chancreous matter may be left in the vagina from previous intercourse. Indeed, I have known a healthy female communicate the disease, which could only have arisen from this cause.

With regard to mercurial rheumatism, I am not yet a convert to the doctrine of Hahnemann, viz., that a disease is produced and cured by the same medicine. Lastly, I have met with nothing to shake my faith in the mercurial treatment of syphilis, and, I may add, that the opinions of Messrs. Guthrie and Rose are in opposition to those of the majority of British practitioners. I am, Sir, yours respectfully,

INVESTIGATOR.

March 7, 1836.

PROPOSAL OF LIGATURES TO BLEEDING VESSELS.

To the Editor:—I beg to draw the interest which you have for matters relating to our profession, I beg to draw your attention to you the following paper (occurring in a very curious and ancient work

completely takes away, I think, the honour which Ambrose Paré the honour which he has won from him by all surgical lessons, and of having been the first who applied ligatures to bleeding vessels. The work is entitled "Gabelhoever's Boocke of Physicke," and was first translated into English in the year 1559, being twenty years before Ambrose Paré's account was published. The following is the extract, taken from page 303, being the commencement of the fourth part:

"If then ther be anye vayne disceded or heved a sunder, you must then knowe that both the endes of the vayne vvhich is disceded doe dravve themselves vpvwardes in the flesh, vvhercof you must indeavour, with little *instrumtes* fit for such a purpose, to take houlde of that ende of the vayne vvhich is shrunk up into the greater parte of the bodie, drawe it forth, and vvith a crooked needle, to stick it, and soe to blinde it," &c.

I trust you will not think this communication of too little importance for insertion in your valuable periodical, as the explosion of any error, even in the history of our profession, cannot be void of interest. I remain, Sir, your obedient servant,

JOHN MOORE NELIGAN.

5, South College-street, Edinburgh;
March 5, 1836.

CHEMICAL AND PHYSIOLOGICAL RESEARCHES

UPON THE

BLOOD OF THE VENA PORTÆ.

PROFESSOR SCHULTZ has communicated, in Rust's *Magazin für die Gesamte Heilkunde*, the results of some interesting chemical researches upon the blood of the vena portæ. In the first part of his memoir he publishes the results of his experiments upon the portal blood of horses, of which the following is a succinct account. He states that

1. The blood of the vena portæ is in general more dark than venal blood, though this difference is not always very distinguishable. It is not reddened by solutions of neutral salts, nor by the contact of atmospheric air, nor by the action of oxygen gas.

2. The portal blood does not coagulate, or do so at any time, it forms cakes, of which the texture is less firm than that of the blood of the vena cava. When the portal blood is exposed to the air, it liquifies, either wholly or partially, in about twenty-four hours, and does, in a similar manner to the portal blood, which does not coagulate, a

great sediment, over which we find a volume of clear serum.

3. Generally speaking, portal blood contains 5.23 per cent in a fresh state, and 0.74 per cent in a dry state, more of fibrin than other venal blood, or arterial blood.

4. Liquid portal blood in general contains less solid particles than other venal blood or arterial blood, i.e. 0.18 to 0.3 per cent.

5. The serum of portal blood generally contains 1.58 less of solid particles, than that of arterial blood, and 0.80 less than that of other venal blood. The first, in a dry state, has an ash-gray colour, the second is yellow, and the third a yellow-green.

6. Portal blood contains proportionally more crassamentum and less albumen. The contrary obtains in arterial blood. The dry crassamentum of the vena portæ is gray and brown in colour. That of other veins is deep-red, and that of the arteries is bright-red.

7. Portal blood contains nearly double the quantity of oily matter that is contained in arterial blood, or blood of other veins, viz.,

In portal blood	1.66.
In arterial blood	0.92.
In blood of other veins	0.83.

8. Dried serum of the vena portæ contains only 0.27 per cent more of oily matter than the dried serum of the arteries and other veins.

9. We find in albuminous crassamentum more albumen by 1.11 per cent than in arterial blood, and 1.21 per cent more than that of the other veins.

10. It is with respect to the quantity of fibrin that the greatest difference is found. Dried fibrin of the vena portæ 10.70 per cent of oily matter; that of the arteries 2.34 per cent, and thus upon the whole the difference is 8.36 per cent.

11. The oily matter of portal blood is brown, black, and unctuous; that of the arterial and of other venal blood is white, or yellow-white, and crystalline; that of chyle is white, two-thirds liquid, and one-third crystalline.

On perusing the paper which contains these statements, the absolute necessity for the adoption of some standard with respect to the fibrin is rendered very obvious. We are aware that after fibrin is dried in the usual manner, the process may be continued until it has become one half less in weight, although the external character shall not be changed. Were the fibrin pressed and dried with a towel, its comparative weight in different diseases would be accurately ascertained, and all we should have to do would be to establish a standard as to the quantity of the fibrin when collected from the blood in the usual manner, and the press and weight of lead employed should also be de-

terminated. When we wish to take a standard for normal blood with which we ought to compare diseased blood, we ought to work quantitatively, by giving, in separate items, the water, the crassamentum, the fibrin, the albumen, and the salts. Such are the rapid changes which diseased blood, particularly, undergoes, that we are compelled to use this plan, for if we enter into such minutiae as LECANU gives us in normal blood, not one chemist in a hundred would ever attempt such a task, nor would the rapidly decomposing blood of a diversity of diseases permit even LECANU himself to investigate any simple disease in such a uselessly minute manner. When we are about to ascertain the gases contained in blood, or any other organic fluid, we should take ten ounces at least, in the manner recommended by Dr. CLANNY in this journal, and submit them to the action of the air-pump. His method of analysis of blood in our pages is also worthy of attention.

EXAMINATION OF FIESCHI'S HEAD.

On the 21st of February, Dr. LELUT, physician to the *Bicêtre*, proceeded to examine the head of FIESCHI, who had been executed on the Place St. Jacques, at eight o'clock on the morning of the 18th. There were assembled a considerable number of the notables in phrenology, advocates and adversaries of the system, and a few literary men and painters, but not a single surgeon.

The cranium presented exteriorly the marks of two wounds, one of which was situated over the postero-superior angle of the left parietal bone, and occupied a considerable surface; the other, much smaller, was seated a little above the extremity of the left eyebrow. Near the angle of the mouth, on the left side, was an oblique cicatrix, nearly half an inch in length, so completely formed, that it might have passed for the mark of an old wound. The external wound of the integuments, above the ear, was not yet closed.

The soft parts were now carefully removed by a crucial incision, and the bone exposed. At the point corresponding with the wound in the left parietal bone, was observed an oval projection of the osseous wall, as large as a crown piece; this prominent portion of the bone was perfectly circumscribed, and bore some resemblance to a watch-glass fixed in its circle. Its surface was throughout uniformly convex, except at a small

point anteriorly. On cutting through the bone, its internal surface, a concave space of the same form and dimensions corresponded with the external projection, and it now became evident that the latter was nothing else than a portion of the skull, which had suddenly and in totality been removed, as it were, by the action of a punch, and being at once replaced by the surgeon, had subsequently united to the rest of the cranium. A very thin false membrane lined the internal surface of the fractured bone, and separated it from the dura mater; however, the membranes of the brain near the wound were perfectly healthy, and presented trace neither of external lesion, nor of inflammation. It was evident the brain had not been injured, a circumstance which explains how the assassin was able to descend from his chamber-window by a cord into a neighbouring court; yet the shock must have been dreadful. The wound on the forehead seemed only to have entered the external wall of the frontal sinuses. FIESCHI, during his trial, spoke of seventeen or twenty fragments of bone which had been removed from his head; this was an exaggeration, if not false, for nowhere could any loss of substance be perceived.

The nature of the wound, and particularly its mode of union, offer several particularities of the highest surgical interest. No doubt M. LELUT will shortly publish a detailed account of the autopsy; in the mean time we have taken the above remarks from the last number of the *Gazette Medicale*, which, as usual, endeavours to show that FIESCHI's head is a complete refutation of phrenology. According to the *Gazette*, FIESCHI's head is completely insignificant in a phrenological point of view. Its absolute volume is very ordinary, while the relative proportions offer nothing worthy of fixing the attention; the forehead is ignoble, the lateral diameters are very short. There is only one single organ evidently developed—viz. *philoprogenitiveness*; that of *habitativity* also is active. The organs of *vanity* and *pride* do not present any projection of note, although those two passions were certainly the key-stone of his whole moral machine. The truth must be told on all these occasions, with candour.

HOPITAL DES ENFANS

PARIS.

**"RESEARCHES INTO THE DISEASES
OF CHILDREN,**

CONDUCTED ON THE

KNOWN PRINCIPLES OF ANATOMY AND
PATHOLOGY.**CHOREA.**

CHOREA, or "St. Vitus's dance," as it is popularly called, is a disease which very seldom terminates in a fatal manner, and it is only occasionally—at very distant intervals—that children labouring under this affection are cut off by some supervening malady. We have had occasion to observe only two necropsies of children who have died while affected with chorea, and the results of an examination were completely negative. The symptoms of chorea are well known to all practitioners who have had the slightest experience in the diseases of children; we shall not therefore recur to them here, or to its treatment. The remedies which have been at different times employed in chorea, are very different. Since the time of Drs. HAMILTON and PARR, purgatives have, we believe, been the favourite remedies with English practitioners, who, amongst the multifarious accidents which they attribute to disorders of the digestive organs, foul bowels, constipation, &c., rank also chorea sancti viti. It is the opinion of UNDERWOOD that it should be so ranked, and of his last "editor," who seems inclined to superadd want of tone in the system. We do not mean to assert that certain cases of chorea may not depend on irritation of the intestinal canal, for such we suppose to be the translation of "foul bowels" into medical language; but we are strongly inclined to regard the opinion as erroneous, which would attribute chorea in a general manner to derangement of the digestive system. On the contrary, we are disposed to consider it as essentially a disease of the nervous centres, occasionally depending on irritation, but in a vast majority of cases produced by causes whose influence we are not yet sufficiently advanced to be able to appreciate. If purgatives are employed, it is true, with some success in the treatment of chorea; hence certain writers, and a great number of practitioners, draw the

No. 654.

logical conclusion that chorea depends upon "worms, foulness of the bowels," &c., and that we must torment our patient with a course of mercurial or aloetic purging. If a large number of cases of chorea be cured by the purgative method, it is because chorea, like certain other nervous affections, yields, generally speaking, to any strong impression made upon the system, and not because the disease depends immediately on disorder of the digestive function, removed by aloes or calomel. We are induced to make this assertion, which will probably appear heterodox to many disciples of the purgative school, by the fact that we have seen a vast number of cases of chorea (of all descriptions, and taken indiscriminately) treated by the simple means of cold effusion, and with the most happy results. For the last few years baths have been the favourite remedy at the *Hopital des Enfants Malades*. They are administered under various forms; cold-baths at the ordinary temperature, immersion-baths at 15°, and sulphureous baths. MM. JADELOR and GUERSENT, who have the care of the scrofulous patients during the winter months, and do not take charge of the acute wards before the arrival of summer, are in the habit, the former, of employing cold baths, the latter, immersion-baths.* Whenever any apprehension is entertained of the existence of bronchitis, either in the acute or chronic form, M. GUERSENT replaces the immersion-baths by sulphureous baths, a remedy proposed about four years ago by M. BAUDELOQUE, who has since continued constantly to employ them. The sulphur-bath is composed by adding about 4 oz. of the sulphuret of potass to a common bath, in which the patient is placed for an hour. Fifteen to twenty baths are in most cases sufficient to remove the disease. Thus, from the month of September 1832 to the month of January 1833, fourteen girls were treated exclusively with the sulphur-baths, one every day excepting on Thursdays and Sundays. Of these fourteen, thirteen were perfectly cured, and the mean duration of the patients' sojourn in the hospital was only twenty-four days. We doubt if any other method can furnish such favourable results. Should the disease resist the administration

* We call an "immersion bath," one into which the child is plunged four or five times successively, instead of being placed in the bath for a certain time.

of ten or twelve baths, M. BAUSSELOUX is accustomed to add the subcarbonate of iron interiorly. During the course of the malady he prescribes a substantial diet and a double ration of wine. The ordinary drink of the patient is an infusion of linden leaf and orange flowers. MM. GUERSENT and JADELOT sometimes administer the oxide of zinc, valerian and megin pills (composed of *Or. Zinci et Valer.*) The acetate of morphia has latterly been tried in four cases, but without any advantageous results. Purgatives are given in all cases where constipation exists, or whenever the presence of intestinal worms is suspected; and if there be any symptoms of plethora, some blood is abstracted from the system. The following cases, to which we might add several others, will serve to illustrate the action of medicated baths.

CASE 1.—Intense Chorea, with Imperfect Paralysis of the Limbs; Matism; Sulphur-Baths; Rapid Cure.

A young girl, ten years of age, recently arrived from Auvergne, of tender constitution, mild character, and excessively timid, was suddenly frightened on the evening of the 10th of January, by a boy who had concealed himself in a hall for the purpose of terrifying her. The girl let fall the utensil she carried in her hand, and at the same moment was seized with irregular movements, and a complete paralysis of the left arm. From the 12th to the 15th, the movements became more irregular and intense; the left leg became feeble, and the patient dragged it after her in walking, like a paralytic person. Her gait is vacillating; she is forced to catch hold of the furniture to prevent herself from falling. During the first two or three days the parents, who had no suspicion of the existence of disease, were constantly reproaching the patient for her awkwardness; a circumstance that considerably aggravated the accidents. On the 17th of January the irregular movements had affected the four limbs, the muscles of the face, the tongue, and the larynx; progression was now impossible, the patient could not articulate distinct sounds. She was brought to the *Hopital des Enfants Malades* on the 19th; her state now seemed very alarming. The child was a prey to the most extreme agitation. It is with difficulty that she could be confined in two beds placed one beside the other, and placed in an angle of the ward. She is unable to speak, or keep the head for an instant in its natural position; it falls to the right or left side, as if the muscles of the neck were paralyzed. She is unable to sit up in bed, or maintain that position when placed in it. The re-

spirations are excessively embarrassed, and the agitation is so violent. The agitation of the patient prevents us from counting the pulse. In the morning, immediately after her arrival, the patient was placed in a sulphur-bath, and kept there for an hour and a half. On coming out she was a little calmer; in the evening a second bath; the day following she took two other baths, with the sulphuret of potass.

On the 23rd, four days after the patient's admission, an evident improvement had taken place. She can answer a few questions, and put out the tongue, with considerable efforts; she took a few spoonfuls of bouillon; the movements of the limbs are less irregular, but still the patient is unable to seize a single object with the hands. A sulphur-bath is administered every day; the drink, *infus. linden et flor. orang.* On the 1st of February the child is able to get out of bed alone, and walk about. On the 5th no trace of the disease remains, except some slight irregular movement of the tongue and a little weakness in the limbs. The expression of the face is natural; progression regular; pulse constantly calm. From the 3rd to the 15th, the general force is much improved; the movements of the tongue become natural; a sulphur-bath is administered six times a week. The diet is nourishing, and on the 15th of February the patient left the hospital perfectly cured.

CASE 2.—Child Thirteen Years of Age. Slight Chorea, attacking simultaneously both Sides of the Body. Four Relapses: Sulphur-Baths Cure after Nine Weeks' Illness and Three Weeks' Treatment.

Sophia Mollet, thirteen years of age, of delicate constitution, small stature, not having yet menstruated, was received into the hospital about the end of September, labouring under chorea for the fourth time. The first attack came on at the age of four years and continued for a month; the second at the age of seven; duration unknown; the third attack at the age of ten, continued for three weeks, and was cured by cold bath. The invasion on these three occasions took place without any known cause; the disease was constantly developed in a slow and progressive manner. The fourth attack, and which the patient actually labours, commenced about six weeks back; it commenced on the right side of the body, and did not extend to the left side before a lapse of three weeks; about the thirty-fifth day the patient began to stammer; headache in front from the commencement; the child's temper was also much changed for the worse; she cries without any cause, and intelligence is diminished. According to the parent's account, the child's face is the seat of constant grimace; progression is irregular, and the patient fell down twice in the way to the hospital. The fingers are

constant movement; the muscular force somewhat reduced; the digestive and circulating systems do not present any mark of derangement. On the day after admission, the patient submitted to a course of tepid sulphur-baths, each bath for half an hour; she was placed on half diet. Up to the 1st of October there was an appearance of amendment; the baths were now prolonged for an hour, full diet was allowed, and the quantity of wine doubled. Under the influence of this treatment, the nervous symptoms completely disappeared, and the girl left the hospital on the 15th of October completely cured.

We omitted to mention that the father of this child had been affected with violent chorea near the age of puberty; her mother was never subject to any nervous disorder, and presents all the appearance of perfect health.

PLEURO-PNEUMONIA ON THE RIGHT SIDE, COMPLICATED WITH PERICARDITIS.

Edouard Loisean, six years of age, of good constitution, had been convalescent of some cutaneous eruption with which he was affected, for several months, when he commenced to cough; to complain of pains on the loins; to exhibit symptoms of fever and dyspnoea; these symptoms persisted, and augmented during eight days, when the patient was transported to the hospital with the following symptoms:—Face slightly yellow, expressing much anxiety; dilatation of the nostrils at each inspiration; cough dry and frequent; no expectoration; respiration deep, costal, seventy-two in the minute; percussion gives a dull sound along the whole of the right side posteriorly and laterally; souffle tubaire, and bronchophony in the two superior thirds; on the left side the sound is clear, and on auscultating we hear nothing but some mucous and sub-crepitant rûle; the skin is warm; the pulse small and feeble, 110; tongue broad and moist; abdomen painful to pressure; two to three liquid stools every twenty-four hours; during the night insomnia, disturbed cries, partial delirium. In the morning we find the intelligence clear, the senses of hearing and seeing intact; when asked where he suffers, the little patient says every where; when we ask him to point out where he suffers most, he places his hand on the back; the physician diagnoses pleuro-pneumonia, in the second degree. *Infusion of Mallows two pots; Gum-draught, with White Oxide of Antimony, and two blisters to the legs.*

During the day the anxiety continued as before; some dyspnoea; some alteration of the countenance; the patient seems very sensible to the application of the blisters.

January 4. The face is pale; the lips are blue; decubitus since the commencement of the disease; dorsal respiration more accele-

rated; we count up to 80 inspirations in a minute. The pulse is too feeble and quick to be counted. The feeble state in which the little patient lies does not permit us to examine his chest; death supervened during the night.

Autopsy.—On examining the body, we find the three lobes of the right lung united together by false membranes, which are soft and easily torn. The surface of the inferior lobe is entirely covered by an albuminous exudation of a slightly yellow colour, in some points at least two lines thick, and uniting it to the pleura lining the diaphragm. The cavity of the pleura does not contain any liquid. The pulmonary tissue of the three lobes is completely impermeable to the air, is dense, and sinks rapidly in water; when pressed between the fingers it does not discharge any fluid. On the left side we do not observe anything more than a slight congestion of both lungs posteriorly; the anterior part is healthy, it presents a little interlobular emphysema. The bronchi are gorged with puriform mucosities, and the lining membrane is of a rosy colour; the bronchial glands are healthy; we do not observe in them any tubercular deposit.

On dividing the pericardium we find the heart enveloped with a pseudo-membranous exudation, reticulated, and of a yellowish-white colour; this is prolonged as far as the origin of the great vessels. The internal lining of the pericardium is covered with a similar exudation, though not reticulated, as in the heart. The tissue of the heart is soft and discoloured. In the interior we find some dark imperfectly coagulated clots; the large vessels are free from disease. Neither the brain nor the organs contained in the abdominal cavity present anything worthy of notice.

This child was brought to the hospital in an advanced stage of the disease, and the symptoms which he presented did not leave any doubt of the existence of pulmonary disease. Auscultation and percussion of the thorax clearly indicated its seat, its nature, and its degree, and even determined its precise extent. The inflammation of the pulmonary parenchyma having appeared to account satisfactorily for the dyspnoea and other accidents, our examination was not carried further than was necessary to determine the lesion of the lung. The precordial region was not submitted to percussion or auscultation, and hence the existence of inflammation of the pericardium was completely overlooked, and not suspected before the examination of the body after death. We are not to conclude from this that pericarditis is a latent malady in children, for in several cases, where the disease existed

free from complication, it has presented the same characteristic signs as in the adult, and was recognised during life.

LARYNGITIS, BRONCHITIS, LOBULAR PNEUMONIA.

Joseph Daniam, seven years of age, of good constitution, had suffered under a very irregular rubella for five days, when he was brought to the hospital on the 16th of October, 1835. Being examined at the visit of the following day, he presented the following symptoms:—Face purple-coloured; respiration extremely embarrassed, 54 in the minute; decubitus, variable sometimes on the right side, sometimes on the left; cough moist, but no expectoration; voice nearly gone; râle crepitant on both sides of the chest; sonority normal; no bronchial respiration, or local pain; tongue covered with a whitish fur; lips dry and cracked; great thirst; belly free from pain; no stool; the intelligence is not disturbed; the child answers clearly when addressed; there is still some trace of the eruption on the limbs; the pulse is small and accelerated, 130. The diagnosis given is, "laryngitis, bronchitis, with congestion of both lungs." *Ipecacuanha* gr. xii; *Antin. Tartar.* gr. i. One blister to each leg; *Infusion of Malloes for drink.*

18. During the day of the 17th the child vomited twice, and passed five stools containing two lumbrici. The evacuations gave rise to but little benefit. Asphyxia is now imminent; the colour of the face is extremely blue; the pulse 150, respiration 56. The cough and alteration of the voice the same as before; no expectoration. The stethoscope furnishes the signs already noticed. When we place the ear on the little patient's chest we distinguish a very well-marked râle crepitant. *Cum Infusion, with Tartar Antin.* gr. vi, and *Syrup Papaver.* ʒi. No vomiting produced; during the day two or three involuntary stools. Died in the night.

Autopsy.—On opening the body twenty-eight hours after death, we observe a violet tint of the integuments covering the posterior surface of the body, and of all the upper part of the thighs. No cadaveric rigidity; the arachnoid is moist and in a normal state; the subarachnoid cellular tissue is infiltrated with a small quantity of serum; the glands of Pacchioni are very numerous, and the veins on the surface of the brain gorged with blood, the cortical substance of the hemispheres is much injected, and when the white substance is divided it presents numerous bleeding points. The consistency of the cerebral pulp is normal. The whole of the mucous membrane lining the air-tubes is red and thickened, from the epiglottis to the minute bronchial ramifications; the latter are filled with a viscid and bloody mucosity. We do not observe any trace of

of any false membrane in the pleura. The lungs are soft and crepitant; their tissue rosy; their surface is marked here and there by some purplish spots, which are much disseminated posteriorly, while in front they are more close. On pressing the pulmonary substance between the fingers, we feel some small nodules, varying in volume from the size of a pea to that of a nut. On dividing the substance of the lung itself, we find the greater part of its tissue healthy, and that the nodules alluded to are so many points of hepatized tissue: they exist in both lungs; there is no very remarkable congestion; no tubercles; the heart and its membranes are in a normal state; abdominal organs healthy.

The pneumonia in this case, instead of attacking one or more lobes of the lung, as in the preceding observation, was disseminated, and constituted what in France is called "lobular pneumonia." The affection presents certain negative characters, which the physician should always bear in mind. Thus, although the pulse and the respiration were excessively rapid (150 and 56), the chest gave a perfectly clear sound on percussion, and we did not observe anything approaching to the *souffle bronchique*. The presence or absence of bronchophony could not be determined, as the patient was unable to speak.

Lobular pneumonia is a frequent disease in children below six years of age. We are not aware that it has been described by any of our English writers on the diseases of children, and it is only within the last few years that its anatomical characters and symptoms have been determined by careful observation at the *Hopital des Enfants Malades*. We shall recur to this affection again, and when we shall have published a certain number of cases, we propose to give a general description of lobular pneumonia.

P. H. GREEN.

ATTENDANCE ON THE SICK POOR.

To the Editor of THE LANCET.

SIR: I have paid much attention to the various plans suggested for giving efficient attendance upon the poor, under the new Poor-law system, but find none of these plans sufficiently simple, or unattended by some great objection.

One great objection to the division of the Unions into districts, which may be taken by a particular surgeon, is, that the surgeon is frequently deprived of a parish, or pa-

ishes, which he has been in the habit of attending; and which, in consequence of his proximity to his residence, have, in some degree, remunerated him for his trouble; and he is obliged, if he take a district at all, to attend parishes at such a distance from his abode, as renders his contract altogether unprofitable, and very injurious to the poor themselves, who have so far to send both for advice and medicine. Local dispensaries I consider altogether useless.

From my experience of the simple working of the self-supporting institution in this town, I am satisfied that the nearer any plan can be brought to the one adopted in that institution, the better it will pay the practitioner, and the more satisfaction it will give to the poor.

Let the Unions be composed of parishes, as conveniently situated as possible for the medical practitioners. Let the number of paupers in every Union, who have, on an average of years, required medical attendance at the parish expense, be ascertained; and, according to their number, let a sum be fixed which may be considered a fair remuneration for the yearly medical attendance upon all the paupers of such Union.

Instead of giving a certain number of parishes to any particular surgeon, let every pauper, when taken ill, apply to the overseer, or the relieving officer, whose duty will merely consist in giving a certificate to such applicant, "that he is a pauper of such a parish." The pauper will then be at liberty to take, or send, this certificate to any surgeon whom he may prefer (who may have agreed to attend the poor of his Union), and he will, generally, to spare himself trouble, apply to the nearest resident.

Let every surgeon preserve these certificates, and at the end of the year (or half-year) let him be paid his proportion of the sum fixed for the whole Union, according to the number of certificates so held, without any reference to the nature of the cases he may have had under his care. This plan, taking trifling cases and severe ones together, will be found a very fair one, and the overseer, or relieving officer, will no longer be called upon to judge whether any applicant may be a fit subject or not for the doctor.

The sum fixed upon for the Union must, in some degree, be regulated by the distance from the medical practitioners, as well as the denseness of the population. In a town of considerable size, the poor can be taken at a much lower rate than in country districts, where the surgeon may have to travel many miles to see his patients. I remain, Sir, your very obedient servant,

JOHN TYRREDALE, M.D.,

President of the Board of Management of the Lynn Self-Supporting Institution.

Lynn, Norfolk, March 8, 1836.

ILLUSTRATION OF THE NECESSITY FOR REGULATING MEDICAL ATTENDANCE ON THE SICK POOR,

ON JUST PRINCIPLES.

To the Editor of THE LANCET.

SIR: I have perused with considerable interest the letters of your intelligent correspondents, "Ruricola" and Mr. Yeatman, on parochial medical contracts, and beg to offer a few observations on the mode of appointing medical officers.

It is proposed by "RURICOLA" that medical men be appointed by the rate-payers; and by Mr. Yeatman, that they be elected in rotation.

With regard to the first proposition, I think it would be adopted with advantage in large towns, where the rate-payers are more independent than in villages, but in the latter places it would only favour monopoly. In villages there is generally one individual who takes upon himself the office of parish ruler, and the rate-payers (many of whom are tradesmen, and derive their support from him and two or three other farmers) are obliged to vote (if they vote at all) for the nominee of this great man. Favouritism and jobbing must, necessarily, be the effect of such a state of things. Under the new system, viz., the election of surgeon by the guardians, monopoly exercises its baneful influence; and I think I can furnish a strong case, proving how necessary is the adoption of Mr. Yeatman's proposition, viz., that medical men should be appointed in rotation. I am living in Broughton, a large village containing nearly 1000 inhabitants (situate only three miles from the far-famed borough of Stockbridge), and it has been for many years the residence of two surgeons. It was customary with my predecessors, and the gentleman who is now living here, to attend the poor of the parish alternately, which arrangement afforded satisfaction to all parties. On my commencing practice, I of course applied to be appointed in my turn to the office of parochial surgeon, but I was told that the arrangement above mentioned would not be acceded to,—that the gentleman who was in attendance would so continue. For this unjust proceeding I could gain no satisfactory reason or explanation, but I at length was informed that the influential man had placed his son with, or was about to apprentice him to, the favoured medical man. Now, Sir, I was no stranger to the poor; I had served my apprenticeship in the village, and, as is the case with most pupils, it fell to my lot to mix with them, and, in administering to their necessities, I studied their feelings; and I am proud to

say, that though they were paupers, I succeeded in gaining their good will and esteem. The medical man in this case, was appointed to afford practice for the young aspirant to medical honours.

Here, then, is an instance of favouritism and monopoly, in addition to the many hundred proofs which you have advanced in support of the assertion, that the benefit of the poor is often made subservient to private interests. And now for the Board of Guardians.

The Poor-law Amendment Act came into operation here last year; guardians were chosen, and among the rest was chosen the great man,—the “*ruling passion*” being strong. The election terminated on Saturday evening; the Board of Guardians met on the following morning at ten o’clock. Mr. “*Ruler*” was nominated Vice, and that gentleman, at the earliest moment practicable, rose and proposed that his favourite medical man (be it remembered, his son’s master) should be appointed to the district. No opposition being offered the motion was carried. Here was a deeply-concerted scheme; no one but those who were interested had the most remote idea that the medical contract would be entered into at the first meeting; consequently, there was no time to arrange or to propose a plan to “*ensure a tolerably minute division of medical labour.*” Hence, seven parishes are under the care of one medical man, whilst I, who live in the centre of them, am excluded from deriving any advantage from attending the poor, either in the way of experience and improvement, or in a pecuniary point of view. I have entered into these details, in order to show the injustice which arises out of the present system, and the necessity of adopting the plan suggested by Mr. Yeatman, as the only one likely to destroy favouritism, jobbing, and monopoly, the existence of which must always prove injurious to the pauper patient.

There are some other points connected with the administration of the new law, which I shall take the liberty to state to you at some future opportunity. In the meantime you will, perhaps, find a corner in your independent journal for the above. I am, Sir, yours respectfully,

L. OWEN FOX.

Broughton, Stockbridge, Hants,

March 8, 1836.

LAW RELATING TO ATTENDANCE ON CORONERS' INQUESTS.

The following letter has been addressed to us by a medical gentleman of Chudleigh:—

Bovey Tracey, Chudleigh, Devon,
March 6, 1836.

SIR: Having read the debate on the bill to provide for the payment of medical witnesses at Coroners' inquests, brought in by you, I could not refrain from transcribing the case submitted by my deceased partner and myself to the Associated Apothecaries, as Mr. Jervis and the late recorder take a different view of the law. (See *Answer 3rd.*) So do you respecting the compulsion to attend a Coroner's summons. (See *Answer 1st.*) After the receipt of this opinion we communicated it to our medical brethren and the neighbouring Coroners; and we suggested to the Coroners that they should require the parish officers to provide a medical man for the inquest, which has been acted on, and by which we have had our fees,—of course, making our agreement with the parish officers previously to giving our attendance. To ensure the future method of remuneration, I would suggest that it be paid by the relieving officer of the Poor-law Union, by order from the Coroner, &c., in cases of paupers. In the cases of respectable people there should be some power given to the Coroner,—what, or by what mode, I cannot suggest.

There is another point to be considered, the certificate given by the Coroner for burial. I consider that, in future, if the Bill for the relief of the Dissenters should pass, the certificate for burial should be addressed to the Registrar of Births, Deaths, and Marriages, who could send it to the officiating minister of the sect to which the deceased belonged, or to the clergyman of the parish. If there should be any inquiries required by you to be made relating to this bill in these parts, I should be happy to lend my assistance. I remain, Sir, yours respectfully,

J. G. CROKER.

To Thos. Wakley, Esq., M.P.

General Committee held at the *Crown-and-Anchor Inn*, June 5, 1820, Jas. Parkinson, Esq. in the Chair.

Resolved,—That the opinion of the Common Sergeant, Knowlps be obtained on the general question of the law, with respect to the remuneration of medical men when called upon professionally to investigate judicial cases before a Coroner.

Resolved,—That Edmond Bacot, Esq. be requested to draw up a case, grounded upon the foregoing resolution, and lay it before the Common Sergeant, and that the Secretary be desired to wait upon him, with Messrs Croker and Langley's letter for the purpose.

“*Case*.—On the 20th of January, 1820, Messrs. Croker and Langley, of Bovey Tracey, Chudleigh, Devon, were summoned by the Coroner of the county to examine the body of a pauper, and to give evidence

before him as to the cause of the death of the party. And on the 9th of January, 1820, they were again summoned by the Coroner to attend for a similar purpose.

"On both these occasions the Coroner gave them a certificate of their attendance, with an order to the churchwardens and overseers of the parish to which the pauper belonged, to pay the fee which has been usual on such occasions, of one guinea for each inquest, but the parish officers have refused payment of the fee. The Coroner says, that it is always usual and customary for the parish to pay these fees in case of paupers, but he has no authority to enforce the payment. Under these circumstances your opinion is requested, —

"*First.* Whether a medical man (not being apothecary or surgeon to the parish to which a deceased pauper belongs) is compelled to attend the Coroner on his summons; and to examine the body of any deceased person, either a pauper or otherwise, and to give evidence as to the cause of the death of such person?

"*Second.* If a medical man is compelled to attend on the Coroner's summons, is he entitled to charge for his trouble and loss of time, and who is liable to pay such charge?

"*Third.* Has the Coroner power to give an order to the churchwardens and overseers to pay a fee to a medical man for attending an inquest upon the body of a pauper of this parish, in consequence of the coroner's summons, and for examining the body of such pauper; and if so, by what means can such order be enforced?

"*Fourth.* Is there any and what difference in the rights of a medical man who is surgeon to the parish to which the pauper belongs?

"*Fifth.* What measures would you advise the parties to pursue, under the circumstances above stated?"

ANSWER.

"1st. I am of opinion that *every man*, medical or not medical, is compellable to obey the Coroner's summons in his legitimate inquiry respecting the death of a subject.

"2nd. By the common law of the land nobody had the power to demand any remuneration for his trouble or expense in attending to give evidence in any criminal case. The 25th Geo. 2 partly gave the court power to order the expenses of the prosecution; that power was enlarged by 27 Geo. 2, and finally extended still further by 18th Geo. 3. In this case a medical man has no power to make a charge for his trouble and loss of time, nor is anybody liable to pay such charge.

"3rd. The Coroner has no legal authority to make any order upon the churchwardens and overseers of the parish to remunerate the medical gentleman who attends, and

gives evidence according to the Coroner's summons. It has been usual for the Coroner, I believe, to make out an order, and for the parish officers to act upon it, but it is certainly not binding upon them, though it would be disgraceful and indecent to withhold from the medical attendant a fair and reasonable fee upon so important an occasion.

"4th. I consider this query answered by what I have said on the second query.

"5th. There are no legal compulsory means of obtaining payment. The only way I could suggest, to obtain payment, would be by stating the case to a vestry meeting, and putting the matter to their sense of honour and humanity.

"NEWMAN KNOWLYS.

"Lincoln's Inn-fields,
June 10, 1820."

"* * Our opinion perfectly coincides with that of the late Mr. KNOWLYS. What we stated in reply to Mr. JENKINS in the House of Commons, was this, — That the coroner had the power to compel the attendance of a medical witness, but that he had no power to make the witness institute a post-mortem examination, or to enforce payment against the churchwardens or overseers, or any other persons, for the performance of that duty when it was executed.

MEDICAL WITNESSES BILL.

A PETITION, of which the following is a copy, was presented to the House by Lord Henniker, a few days ago. In attaching signatures to the petition, the feeling as to the justice of the claim appeared to be equally strong with all the gentlemen who signed it. Indeed, Mr. Denham, to whose praise-worthy industry it is due, informs us that it seemed only to be required that some one person should act first in the matter, to induce them unanimously to lend their aid.

To the Honourable the COMMONS of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

The Petition of the undersigned practitioners of medicine and surgery, resident in the stated towns and villages in the county of Suffolk, humbly sheweth,

That your petitioners are fully convinced that in a great majority of cases of sudden and violent death, it is utterly impossible for a coroner's jury to arrive at a right conclusion as to the cause of that death, without the testimony of a medical witness, founded on a post-mortem examination of the body.

That considerable danger to the life of the patient is incurred because those gentlemen had in surgeon not unfrequently attends the making such post-mortem examination, which requires great skill and anatomical and pathological knowledge, not to be acquired without considerable study and expense, and often not without risk of life, to render it efficient for the purposes of evidence.

That your petitioners are liable to imprisonment if they neglect to obey the summons of the Coroner to give evidence at the inquest; and that, in many instances, several hours are occupied by the Coroner in prosecuting the inquiry, during which the surgeon is often obliged to wait, at very great inconvenience to himself.

That the Coroner possesses no authority to order remuneration to be given to medical witnesses for the heavy sacrifices which they are thus obliged to make.

Your petitioners, therefore, humbly solicit your honourable House to take this their petition into your earnest consideration; and to award them such fair remuneration for their services as shall seem to your honourable House to be sufficient and just.

And your petitioners, as in duty bound, will ever pray, &c.:—

FREE HOSPITAL,

GREVILLE-STREET, HATTON-GARDEN.

THE ninth annual meeting of Governors was held at the *Gray's Inn Coffee House*, on the 23rd of February, and again, by adjournment, on the 1st of March. About 300 attended the first meeting, and 200 at the second. At the preceding quarterly general meeting, notices of motions were given for the removal of Mr. Hensch the resident apothecary, and Mr. A. Tweedie one of the

proposers, because those gentlemen had in favour of a *quack nostrum* for the protracted cure of gonorrhoea, which had been freely advertised with their names, that of the former being dated from the "Free Hospital." The proposers of the proposition for the removal of Mr. Hensch and Mr. Tweedie, urged in their notices of motion that "one of the principal objects in instituting the hospital, was to lessen, and if possible to annihilate, the mischievous consequences resulting from diseased persons being deluded by advertising quacks," and that the advertising of the testimonials had materially injured the reputation of the institution. Against Mr. Tweedie they also complained that he had also "without consulting with his medical brethren, administered to the hospital patients under his care, the nostrum."

After the yearly report had been read,

Mr. MARSDEN spoke to the following effect:—He regretted seriously the occasion of so large an attendance of the subscribers, but one of the chief objects of the charity had been violated, and he felt it his duty to call attention to the fact, declaring that he was actuated by no private or personal motive in the step. Since the publication of the "testimonials," several subscribers had seceded from the charity, believing that the officers were encouraging quackery, and a representation of the fact was made to Mr. Hensch and Mr. Tweedie, and a sort of promise obtained from them that the cause of complaint should be removed, but without realization. Therefore he, Mr. M. felt compelled either to retire from the institution altogether, or take the opinion of the governors as to the propriety of recalling the testimonialists, and thus sever the name of the hospital from the objectionable advertisements. If he, Mr. M. had erred in this course, the meeting would fearlessly say so, and censure his conduct. Mr. M. then proposed a resolution for the removal of Mr. Hensch, which was seconded by Mr. WATSON.

Mr. HENTSCH rose, and read his reply. When he gave the testimonial, he did not know that it would be published. The medicine was not a *nostrum*, but a new form of an old and well-known drug. He had requested the withdrawal of his testimonial, but the advertiser of the medicine refused to withhold it. He (Mr. H.) believed that personal motives alone induced this proceeding against him. He had faithfully discharged his duty, and now demanded justice at the hands of the meeting.

Mr. MARSDEN said, that if it were not a *nostrum*, and Mr. Hensch would make known the composition, (Mr. M.) would at once withdraw the resolution.

Mr. JOHN STEVENS moved a similar resolution respecting Mr. Tweedie, and it was

seconded by Mr. ALEX. GALLAGHER. Both gentlemen spoke against the promulgation of quack medicines, and lamented that Mr. Tweedie had aided the purpose of a quack on the present occasion, especially as the professional talents and character of Mr. Tweedie were of a high quality, on which account he (Mr. G.) exerted his influence to procure for him the office he held in this institution. However painful, therefore, the circumstances were to him (Mr. G.), he did not hesitate to second the resolution.

Mr. TWEEDIE, with much eloquence, defended his position as surgeon, on grounds similar to those urged by Mr. Hentsch, and read a copy of a letter which he had addressed to the Council of the College of Surgeons, in answer to which, the secretary of the College had replied, that the Council "could not believe that the governors of any public institution would remove any medical officer for having tried a new method of administering an old and well-known medicine."

A GOVERNOR observed, that it was not for *that*, but for having *used* and recommended a secret nostrum, that these proceedings were instituted against Mr. Tweedie.

Mr. TWEEDIE concluded by stating that he would not be alarmed into the act of resigning, either by observing the number of governors present, or by a knowledge of their opinions. The merit, or the demerit of his dismissal, must rest on their own shoulders.

Mr. BRANBY COOPER, a newly-made governor, said, that he had himself used the medicine, and after applications from the proprietor on five successive days, he had given him his opinion in writing, rather than be troubled again on the subject, but had he known that the certificate would have been published, he would have lost his right hand sooner than give it. It was, however, not a nostrum, but a preparation, which, if he were to explain, would not be understood by any one present. *Cries of "explain," "explain."* He declined explaining. Was he, or his friend Mr. Green, or Mr. Tweedie, to be publicly called to account by Mr. Marsden? Who was Mr. Marsden? He had never heard even his name until recently, and he believed that if there was any quackery at all in the business, it emanated from the party who had brought the matter forward. He (Mr. C.) had the honour of holding one of the first appointments in one of the first institutions in this kingdom, and he (*snapping his fingers*) cared neither for this charity, nor for the opinion of its governors, and sooner than submit to such treatment, by ———. (Here the meeting were so opposed to the impetuosity and the expressions of the speaker, that he was obliged to resign his

seat, and general hissing followed his final resignation.)

Mr. H. WATHMAN defended the conduct of Messrs. Hentsch and Tweedie, and moved an amendment upon the motion against Mr. Hentsch.

Alderman HARMER said, that as the "testimonials" continued to be published, it would be impossible for the writers to be allowed to retain their offices in the institution, without upholding connivance at a disgraceful system of quackery in physic. He eulogized the professional character of Mr. Tweedie, and should be ready to help that gentleman to any other appointment. He was satisfied that no personal pique occasioned the introduction of these motions.

Dr. UWINGS (a physician to the institution) defended the testimonialists, and stated that he had that very morning recommended the secret medicine to one of his near relatives. He would resign if Mr. Tweedie were removed.

Dr. RYAN (also one of the physicians) and Mr. LUCAS both defended the conduct of Mr. Tweedie, and concluded by stating, that they would resign if the resolution against Mr. Tweedie was carried.

Mr. GREVILLE JONES, another of the medical officers, paid very earnest compliments to the integrity and talents of Mr. Tweedie; but he declared against the quack testimonial system, whether the medicine were good or bad; for the public were not competent judges of diseases and their modifications. There was extreme imprudence in Mr. Tweedie's allowing the possibility of his name being connected with such a system, and the imprudence on the part of the surgeons of *St. Thomas's* and *Guy's Hospitals* was still less excusable. Whichever way the question terminated, the discussion would teach many eminent men not to let their good-nature or personal attachments betray them into supporting a system of plunder, frequently fatal to human life, and always injurious to their professional brethren.

After several other speeches *pro* and *con*, the meeting divided. On the motion against Mr. Hentsch, the show of hands was,—For the motion, 200 and odd. Against it 61.

On the motion (on the second day of meeting) against Mr. Tweedie, the show of hands was declared to be 5 to 1 for the motion.

The usual business of the annual meeting was then gone through, and the meeting dissolved.

In consequence of the days of meeting of the *Medico-Botanical Society* coinciding with those of the *Medico-Chirurgical*, it has been determined by the Committee to alter the evenings of the Botanical Society's meetings from Tuesdays to the second and fourth Wednesdays of the month.

MEDICO-CHIRURGICAL SOCIETY.

ATROPHY OF THE VALVES OF THE HEART.

The following is an abstract of a paper, read at the above Society, on the 23rd of Feb. and the 8th of March, entitled, "Remarks on Two Forms of Atrophy of the Heart's Valves, which interfere with their Function; founded on Cases, by Dr. P. N. KINGSTON, Physician to the St. George's and St. James's Dispensary."—

The first of these lesions, which, says the author, has hitherto been altogether overlooked by pathologists, has been observed by Dr. Kingston in numerous cases, in eight of which it had proceeded to a considerable extent. It was defined, "A simple shortening of the heart's mitral or tricuspid valve, without any diminution of its natural thinness, pliancy, and transparency, the orifice to which it belongs having at least the ordinary caliber."

The second of these lesions (to which the aortic and the pulmonary, as well as the auriculo-ventricular valves are liable) is nearly allied to the preceding in its nature and effects:—"When so altered, the continuity of the valves is interrupted by apertures, sometimes of a large size, and sometimes so numerous as to reduce the structure to a mere network, while the remainder of the valve is in a state of attenuation, which is here and there often extreme, especially towards the edges of the apertures." In five of the cases, a considerable portion of the valve had been thus affected. The only preceding writer who has at all noticed this appearance, is Laennec, who has merely glanced at it. These lesions are not very rare, but they are very liable to be passed unnoticed, unless the attention has once been directed to them.

A valve which has become shortened or cribriform, is, of course, incompetent to close completely the orifice to which it belongs, and hence permits that regurgitation which it was placed to prevent. From this disablement of the valve arises a strong tendency to dilatation or hypertrophy of those parts of the heart which are posterior to the valve affected, to palpitation, to venous congestions, to anasarca, and to effusion into the serous cavities, and, where the mitral valve is defective, to dyspnoea and cough also to pulmonary congestion and inflammation, and to some of those symptoms which are apt to arise from a deficient and irregular supply of arterial blood to the head, and the remote parts of the body. A morbid "bruit" may, in some cases at least, be perceived with the stethoscope. Where the tricuspid valve is affected, there is distention, and sometimes pulsation, of the external jugular veins. Where the mitral

valve is affected, the pulse is small and weak in comparison with the heart's impulse, and it is liable to be irregular and unequal.

By a reference to these symptoms, and to the circumstances out of which the complaint arose, it may generally be ascertained whether or not there is valvular disease. The discrimination of these from the other valvular diseases is a point of great nicety, on which the author stated that he was not as yet fully prepared to speak.

These defects may now and then be congenital, but in all the present instances they had evidently been produced, long subsequently to birth, by those species of absorption which are unattended with suppuration, a conclusion which coincides with Meckel's opinion respecting similar defects of the valves of the veins. From the histories of the cases, and from numerous analogies, Dr. Kingston infers that their most frequent causes were either, 1st, debility of the valve's nutritive powers, combined with undue force of the blood's impulse (from hypertrophy of the ventricle, over-exertion, &c.); or, 2ndly, so great a degree of local debility (often consequent on gouty or rheumatic action), as to render the valve liable to be absorbed under the pressure to which it is naturally subjected.

The author concluded by pointing out the errors which may have arisen from an oversight of these lesions at post-mortem examinations,—the practical advantage of detecting them during life (even so far as to perceive that there is some valvular defect obstructing the circulation),—the means by which the frequency and extent of the lesions may be diminished,—and the circumstances under which it may be hoped, either that the valvular structure may be restored to its original dimensions, or that the corresponding orifice and cavities may gradually diminish in caliber, so as to become adapted to the altered size of the valve.

THE LANCET.

London, Saturday, March 12, 1836.

Active exertion under oppression and the infliction of injury, becomes the duty of intelligent men. We expected that the medical practitioners of this empire, when they found that there was a chance of obtaining from the Legislature a protection against the annoyances to which they have been subjected at Coroners' inquests, would come

forward and energetically support the cause, however humble, of those persons who should advocate their cause in the House of Commons. The events of the last fortnight have proved that we did not make a wrong estimate on this subject. The petitions from medical practitioners continue to be presented to the House daily, all praying that medical witnesses at coroners' inquests, may receive some compensation for such services as those which they have hitherto almost invariably been required to bestow gratuitously, in aid of the maintenance of the cause of public justice in this country. After the MEDICAL WITNESSES BILL has left the Commons, we will furnish our readers with the names of the places whence petitions may reach or have reached Parliament, when a statement will be exhibited which will prove to the members of the profession resident in this metropolis, how ably and faithfully the surgeons of England and Wales can discharge their duties to the interests of that profession which has the good fortune to claim them as its members.

There are a few stupid and narrow-minded writers, we perceive, who insist that the MEDICAL WITNESSES BILL refers merely to a medical question, and they discuss with characteristic sagacity, what they are pleased to denominate "its merits." In rendering this important service to the public, it is satisfactory to observe that their efforts in the way of reasoning are admirably proportioned to their ignorance of the subject under investigation. Why do not the conjurers ask themselves this question—"Of what use is the Coroner's inquest, on really important occasions, in the absence of competent medical witnesses?" If they had sense enough to answer this simple question, the effusions of their brains might terminate. It ought never to be forgotten, that as the Coroner's court is now conducted, the chief officer and his jurymen are as likely as not to become the tools of quacks and charlatans. In cases of death from

malapragis, from mineral poison, from "Morison's Pills," from dexterously-administered vegetable poison, where are the aids of justice if they cannot be discovered in the experience of the pathologist, and the researches of the chemist? Better, at once, as we have frequently stated, abolish the Coroner's court altogether, than continue to withhold from medical men a just reward for the services which they execute in that court, and to allow non-medical functionaries to preside over its proceedings. At many of the inquests which have lately been held, the powers of this institution, when they are properly exercised, must have forcibly attracted public attention, and have illustrated what has so often been stated in the pages of this Journal, with reference to the shield which, under many trying circumstances, it presents to the community. The Bill, therefore, which is now before Parliament, is only one step towards improvement in this important branch of our judicature, but it must, necessarily, lead to many others of a satisfactory character.

It is alleged, we find, by Mr. Cripps, and other gentlemen who consider that medical witnesses ought not to be paid for their attendance at coroners' inquisitions, that the proposed Bill introduces a distinction, with reference to one class of persons, which may with propriety be claimed by the members of all other trades and professions. What folly! Take the medical practitioner in his character as an ordinary member of society, or as a casual observer of the circumstances which produce death, and he is content to stand in the court upon an equality with every other individual who is similarly circumstanced. But what is the fact? In not one case out of a hundred is he summoned as a private individual,—as a casual spectator,—but as a member of a learned and most useful profession; and in his professional character, therefore, is he called upon to act for the edification of the coroner and his jury. This distinction is so

evident, so striking, so convincing, so unequivocal, as an indication of the peculiar duties which the professional witness has to execute, that all that remains on the subject, which admits of a patient notice or consideration, is comprised in an answer to the question,—What is an adequate remuneration for the labours which a medical witness is required to discharge? Although we cannot hope that an answer, which shall be fully satisfactory to this question, will be acted upon in the House of Commons, yet, from the manner in which the medical petitions are received in that House, and from the liberal spirit with which the motives for introducing the MEDICAL WITNESSES BILL was regarded on both sides of the House, it is hoped and expected that an award will be made somewhat approaching to the importance and the justice of the demand. In reality, the question which the Commons are now to determine is, whether the Coroner's Court shall henceforth be a useless institution, and a profitless drain on the county rates; or whether the public shall find that it is a source of protection against the merciless impositions of quacks and other criminals.

Never have quacks, quackish doctrines, and quack medicines, exercised a greater influence over the minds and bodies of the people of this country, than they exert at the present epoch. Are such evils to be patiently endured by the scientific members of a noble profession? Common sense, common honesty, and philosophic attainments, alike forbid so scandalous and disgraceful an imputation. The source of the existing evil is to be found in the odious, the exclusive conduct of our rotten and contemptible medical corporations. The College of Physicians, with an ample store of vain conceit and malignity, has done its best to be mischievous; but the members of that corporation having always been limited, its quackish exclusiveness has been

more for its absurdity, and the business of its members, than for the amount of positive injury which it has inflicted upon the community. But the results of the conduct of the College of Surgeons, although that conduct has been somewhat similar, have outstripped all comparison with those of the establishment in Pall-Mall East. A precious game have these two institutions been playing during the last six-and-thirty years, and it is scarcely surprising to observe that the murderous quacks are sought after by the community, to the exclusion and rejection, in case of need, of licensed practitioners in medicine. The College of Physicians commenced their career by passing a law of exclusion against surgeons. Practitioners of surgery were not deemed worthy of admission into their body. The College of Surgeons, admiring this prudent and general system of exclusion, went a step farther, and a Council, consisting of the self-elected pukes of our hospitals, resolved that no surgeon in general practice, that is, that no general practitioner, should be admitted to a seat in the Council. Thus the public were told by the two English Colleges, which had been appointed by royal charter to protect the interests of the profession, and, above all, the health of the community, that surgeons who were engaged in executing the duties of medical practice in all the departments of the profession, were not deemed by the heads of their own colleges qualified to be received on equal terms with themselves, into those national establishments. The Colleges, in short, were industriously employed in *disgracing* the great majority of the profession, and THE RESULTS are now before us. Quackery is rampant, and the poison of quack medicines is spreading desolation around, with a virulence and a fatality not exceeded, probably, by that of the plague or the cholera. We are not to draw our inferences of its effects from two or three, or even from fifty inquests; no, not even from a thousand, though as many were to be held

in a single year. We are to look upon the fatal consequences which are so inevitably happen from placing a reliance on the powers of a supposed curative agent in ALL diseases. We ask,—In thousands of instances where the results are fatal, will the relatives and friends—the secret abettors of quackery—at once, by acknowledging their delusion and folly, *make a confession of their guilt?* Nothing can be more absurd than to entertain such a belief. The unfounded, the monstrous reliance which is placed by an uninformed public on the powers of quack medicines, must, from the natural course of things, be followed by the most frightful catastrophes, and it is equally true that the confessions of error will be of small amount. It is not easy to obtain an acknowledgment of the imperfect operations of the judgment, because pride is ever interposing to shield the mind from self-exposure. Every experienced quack is well versed in these weaknesses of our nature, and shapes his course and frames his stratagems accordingly. The ignorance of the community is the soil which they cultivate, and the press is the machine which is set in motion for securing to them a full harvest for their labours.

What, then, is to be done to counteract the operations of these infamous marauders? The indications are simple and striking. The might of the press must be turned against its mercenary abusers, and the ignorance of the people on medical subjects, must be made to give place to rational views of the science, before a hope can be entertained that the existing pestilence will experience shock or check in its reckless career. Without the aid of the press, quacks would be as powerless as other impostors, and even with the use of that engine, were it not for the indiscriminating ignorance of the public, it could not be rendered available to their nefarious purposes.

Fearing, therefore, that the Government will take no immediate steps for exterminating quack medicines, and sending their

inventors and proprietors to the hulks, we call upon the members of the medical profession in England to take the matter seriously, and at once, into THEIR OWN HANDS. They should instantly institute,—by a general subscription, and a combination among themselves,—an

ANTI-MEDICAL QUACKERY SOCIETY,

having its Central Board, with an efficient paid secretary, constantly sitting in the metropolis, composed of the legally-qualified members of the profession, without distinction. Its connections would necessarily be ramified throughout the entire kingdom, and the whole powers and energies of the society, thus organized, should be concentrated on two objects, one *present*, the other *remote*. The *first*, that of apprizing the public in every town and village of the empire, through the medium of anti-quackery tracts, to be supplied from the Central Board, of the murderous results of taking quack medicines; and, *remotely*, to obtain, by a well-organized process of petitions, the total suppression of the sale of stamped, patent, and secret medicines, through an act of intervention of the Legislature.

The expense of carrying this scheme into execution would require only a very small contribution from each legally-qualified medical practitioner, and the advantages to be obtained by its operation would, we are convinced, be almost concomitant with the first hour of its institution. At any rate, it is a subject which we believe will be found, on reflection, to merit the deliberate attention of the profession.

Having thus put forth the suggestion, we shall, in the next LANCET, take a more extensive view of the question, and endeavour to illustrate what would be the advantages of the acts of a Society such as we have now proposed.

At the Spring Assizes held at Winchester on Friday, March 4th, Jane Metchear, "an interesting girl," says the reporter of *The*

Times, "was indicted for the wilful murder of her new-born female child, at Southamptⁿ, on the 18th of September last.—Mr. Saunders conducted the case on the part of the prosecution; Mr. Missing for the prisoner." Several witnesses were examined for the prosecution; and, after a trial of seven hours, the jury returned a verdict of "Not guilty of the murder," but "guilty of the concealment," and she was sentenced to three months imprisonment. At the close of the report, the writer of the statement adds the following observations:—

"One thing is worthy of remark. The surgeon who was first called in, and who examined the person of the prisoner, and the child, afterwards presided as coroner at the inquest sitting on the body of the child, when the jury returned a verdict of 'wilful murder,' and he eventually gave evidence against her on the trial, having previously acted as judge in the case. Without, in the slightest degree, casting any imputation on this gentleman, we cannot but consider this as a state of things which ought not to exist, and it is a very strong argument against the appointment of medical coroners."

The "argument" which the writer, a barrister, most probably,—suggests in this case, as showing the impropriety of appointing medical men to fill the office of coroner, is exactly such an one as we should expect to hear, not from an intelligent reasoner, but from a parchment-headed scribbler. Did it not occur to him that medical coroners might *not* be engaged in medical practice, and that it is in the power of the law to institute such a protection, if it be a wise one? But, as a lawyer, he ought to have known that the medical coroner in the case in question had no alternative. Having attended the prisoner in the course of his practice, how could he conjecture, before the result was known, that an inquest would be necessary? And when it was deemed necessary, for the ends of public justice, that an inquest should be held, then he was *obliged* to act as coroner, because it was not in his power to appoint a deputy. No imputation whatever, therefore, can be justly cast upon the coroner, for acting as he did at the inquest, and at the trial in question. That the law is loose, and most imperfect with regard to the office of coroner, generally, we willingly confess; but, before it is mended, it must find other correctors than the sapient critic of *The Times*.

MACULATED.—At the last meeting of the Bath Medical Society, Dr. Sigmond made some observations on the most eligible method of drying and preparing the leaves of *cañium maculatum* for medicinal use. The leaves being in a high state of preservation, and entirely freed from their stalks, and as much as possible from external moisture, they should be laid in thin layers on willow baskets, stripped of the bark. They must be placed in a room from which all light is excluded, and then submitted for three or four hours to a heat of a little below 212° of temperature. Having been then turned, they should be exposed to the same heat for about eight hours. They are then crumbled by the hand, with great facility, into a fine powder. Dr. Sigmond showed a good specimen of the powder prepared in this way. Dr. S. considered that the autumnal season was the best for gathering the leaves.

IMPURE CASTOR OIL.—Dr. Sigmond also cautioned the profession against a fraud which had been extensively practised by a company who had invented a process, by which rancid and ineffective castor oil could be made apparently sweet and good. It is, however, perfectly useless, and possesses no purgative power. Great quantities have been disposed of, and he thought well that the system should be exposed.

MEDICAL WITNESSES' PETITIONS.

To the Editor of THE LANCET.

SIR: The members of the medical profession must be much gratified at the manner in which the announcement was received by the House, on Tuesday evening, the 1st instant, of your intention to introduce a Bill for granting remuneration to medical witnesses, for their attendance at coroners' inquests. The subject was introduced at the monthly meeting of the medical society of this city, on Friday evening last, and a committee was appointed for the purpose of drawing up petitions to both Houses of Parliament, which they have done, and they will probably be signed by all the medical men in the city and neighbourhood. Enclosed is a copy for publication in your widely circulated journal, should you consider that its appearance would excite others to follow our example. The favourable reception of the motion for leave to bring in the Bill, does not justify us, in my opinion, in relying upon the first success of the Bill, but it becomes the duty of every member of the profession instantly to embody his sentiments in a petition, and forward it to the only quarter for redress. I am, Sir, in haste, yours, &c.

G. KING.

3, New King-st., Bath, March 9, 1836.

* In another part of this volume, Sir, we have inserted a copy of a petition received this week, and that we must will serve the same purpose as would the insertion of the petition forwarded by Mr. King, and many others with the same important prayer, which we have within the last few days received from medical gentlemen in different parts of the kingdom.

LATE ADDRESS TO APOTHECARIES' HALL.

To the Editor of THE LANCET.

SIR: I was truly astonished to learn how chicken-hearted the students of the *London University* had become when they sent their address to the Hall. I thought they possessed more courage and more knowledge than to fear the Rhubarbians. How are the vaunted fallen! How have the students of my alma mater degenerated! In days gone by, no document would have been signed and forwarded to the Blackthurs establishment with any evidences of fear or want of favour. The students would have had more confidence in their abilities and acquirements, than to bow and pray for mercy before Ridout and Co.

I perceive in the list some names of 1832-men. M**rh**d, W**k***d, and others, I blush for you. Among others I see J. D**r**ne. Are you afraid, too? "Tell it not in Gath."

I am, Sir, yours,

AN OLD STUDENT IN THE PROVINCES.

March 7, 1836.

METROPOLITAN INFIRMARY FOR CHILDREN,

Broad-street, Golden-square.

MEASLES FOLLOWING CROUP.

GEORGE COOPER, aged 5, a remarkably fine and robust boy, was entered as a patient under Dr. TWEEDDALE, on Monday the 29th of February last. The little patient was labouring under the frequent, dry, hoarse cough which is peculiar to croup. His skin was hot and dry; the face flushed; the eyes suffused; the tongue white and furred; pulse 130, full; bowels costive; he complains of headache and lassitude. His mother states that on putting him to bed on Saturday evening she noticed that he had a hard dry cough; he was very feverish all day on Sunday, and in the evening she procured some medicine for him, which made him very sick. Then leeches were applied immediately to the throat, and three grains of calomel, and five of powdered scammony, were given every two hours until the

bowels were well purged, and a tablespoonful of a mixture containing liquor antim. tart., and oxymel of squills, of each five drachms, and four ounces of saline mixture, were ordered every two hours.

Vespers.—The leeches have bled freely; the bowels have been well opened; he has vomited, several times, a quantity of thick mucus, with small portions of fibrine. Two grains of calomel and three of James's powder, were ordered to be given every four hours. The mixture to be continued. To be put into a warm-bath up to the hips.

March 1. Still feverish; pulse 110, and small; cough much relieved. The surface is covered with the eruption of measles. Three grains of calomel and six of scammony powder, ordered to be taken directly. The other medicine to be continued.

2nd. Fever much abated; bowels do not keep open without medicine; pulse 100, small; cough still troublesome, though there is not so much expectoration; the eruption is developed more fully; he is able to sit up in bed; a blister was applied to the chest, and a purgative was given night and morning. The powders and mixture discontinued. He continued to improve, and is now convalescent.

This is the second case, in the infirmary, of croup followed by measles, terminating favourably under the same plan of treatment. The first patient was a healthy boy, eight years of age, who was bled from the arm, and had leeches to the throat.

ST. BARTHOLOMEW'S HOSPITAL.

TUMOUR ON THE SCAPULA.—James Jackson was brought into the hospital with a large tumour, occupying the left scapular region, of about the size of two-thirds of a large melon. A tumour of about half that size had been removed, five months previous, from underneath the scapula, by Mr. EARLE, but the disease returned, and increased to the above magnitude, continuing rapidly to enlarge up to the day of the operation. From the condition of the old cicatrix it was by some authorities deemed malignant. The operation was performed by Mr. SKEY. The man, after some loss of time occupied in determining his position, was finally placed in the recumbent posture on the operating-table, lying nearly on his face. The operation was commenced by an incision, forming a part of a small flap, reflected towards the shoulder, which exposed the spine of the scapula, over the flae at which it was afterwards divided. Two other large flaps were made, each forming nearly a semicircle; the one directed upwards towards the side of the neck, the other downwards. All the muscles of the dorsum of the scapula were

then divided, for the purpose of exposing the bone in a perpendicular line, about one-third distant from the glenoid cavity, towards the base. The spine was divided by a common amputating-saw, the upper portion of the bone by Hey's saw, and the lower fossa was split up with Liston's forceps. The hemorrhage was then considerable, but was arrested by the assistants, each of whom seized one or more vessels. Moreover, the subclavian artery was compressed above the clavicle; an incision, nearly fifteen inches in length, was then made along the basis of the bone, but between the spine and the old cicatrix, the whole of which was removed. The tumour was rapidly dissected from the ribs, and removed, and the bleeding arteries were tied. A small portion of the disease was found adhering to the neck of the bone, close to the shoulder-joint, which was dissected off with a silver knife.

On the conclusion of a consultation which was then held on the case, the patient was recommended to undergo the removal of the whole upper extremity. To this he would not consent, and Mr. S. removed the remaining part of the muscle, close to its insertion into the humerus. The wound was united by sutures, and the patient retired, much exhausted from the loss of blood, having been on the table nearly three-quarters of an hour, of which period the removal of the tumour occupied but twelve minutes.

Secondary hemorrhage occurred within a few hours, and on securing the vessels the wound was dressed with lint. Thirty-five drops of laudanum were given to him. He remained quiet throughout the night, and on the following day he took repeatedly small quantities of beef-tea. The operation was performed on the 22nd of February. Up to the present time he has had no bad symptom; the wound is covered with healthy granulations. The tumour was composed of the same structure as that for which the former operation was performed, viz. albuminous sarcoma. More than half the scapula was entirely absorbed. The tumour was moveable on the ribs, which were perfectly healthy.

NORTH-LONDON HOSPITAL.

SCIRRHUS OF THE BREAST.—OPERATION.—Mary Welch, aged 47, a milkwoman, was admitted on the 16th of February under the care of Mr. COOPER, on account of indurated enlargement of the right breast, of six months' duration, consequent upon a severe blow received about that period. The swelling became gradually larger, and is now about the size of a man's fist; the nipple is depressed; the tumour is hard, craggy, very firm, and very moveable. The axillary glands do not appear to be affected. She

has been a subject to sudden lancinating pains from the breast up to the shoulder and down the arm. The skin is not discoloured; menstruation is regular, but more scanty than it has previously been. She has borne nine children. Mr. COOPER recommended the removal of the tumour; to this she consented, and on the 18th he proceeded to operate. He first made two elliptical incisions, and dissected from below upwards, first on one side and then on the other. Two arteries were cut in the first incision upon the inner side. The fingers of an assistant instantly suppressed the hemorrhage until the whole mass was removed. About five vessels were tied, the largest in the substance of the pectoralis major. The two integumental vessels, which bled very smartly at first, had now contracted within the subcutaneous adipose tissue, and appeared much smaller than at first. There was another vessel tied, at the upper angle of the wound. A small portion of scirrhous tissue having been left behind, it was removed. The sides of the incision were brought together with several broad strips of adhesive plaster, the ligatures hanging out in the interspaces; a compress of wet lint was applied over the plaster, and then a broad piece of cloth was pinned around the chest. Her arm was placed in a sling, and she was sent to bed. Mr. COOPER prefers the broad piece of linen to a bandage, as, in case of secondary hemorrhage, it is easily tightened without requiring to be first removed. This plan he has known to succeed in several cases where secondary hemorrhage has occurred. Indeed, according to his experience, secondary hemorrhage is more frequent after this operation than almost any other. In the evening the patient took half a grain of the muriate of morphia, and was then pretty easy.

19. Is doing very well. Passed a quiet night, but did not sleep much. The morphyne to be repeated to-night.

20. Has slept during a considerable part of the night; pulse quiet, skin natural.

23. The wound was dressed to-day. It has united at several points, though in others the edges have retracted considerably. Her general health is unaffected.

Mr. RANDAL, of Oxford, surgeon, is coroner for the borough of Aldeburgh.—W. D.

(Advertisement ?) "Dr. Hall has resigned his office as Lecturer on the Practice of Medicine at the Aldersgate school. Dr. Hope is to succeed him."

A Subscriber.—We lament to say that the claim cannot be enforced under any existing law.

LECTURES

ON

DISEASES OF THE BRAIN AND NERVOUS SYSTEM,

NOW IN THE COURSE OF DELIVERY IN THE UNIVERSITY OF PARIS.

By M. ANDRAL,

Physician in Chief to the Hôpital de la Pitié, and Professor, and Lecturer on the Principles and Practice of Medicine, in the Faculté de Médecine of Paris.

LECTURE XVI.

RAMOLLISSEMENT OF THE NERVOUS CENTRES.

(Continued from p. 927.)

GENTLEMEN,—Let us now pass to ramollissement affecting other parts of the brain than the cerebral hemispheres. The first which naturally present themselves for examination are,

The Corpus Callosum, the Septum Lucidum, and the Fornix.

We have already described the anatomical characters of the lesion when situated in those parts, and have now merely to occupy ourselves with the functional derangements to which it may give rise. We shall only add on the present occasion, that, when softened, we generally find the ramollissement accompanied by another lesion, viz. effusion of a serous fluid into the cavities of the lateral ventricles; this certainly occurs in a great majority of cases. Whenever ramollissement occupies the white central parts of the brain, it is very rare not to find at the same time a greater or less quantity of serous effusion in the ventricles. The ramollissement is, then, nothing more than a constituent element of the disease so generally known under the name of "acute hydrocephalus." However, we cannot now enter into an explanation of this latter form of ramollissement; it is foreign to the question which now occupies us, and however

interesting in itself, it would lead us too far from the principal subject of our study. We must, therefore, confine ourselves, for the present, to cases in which *Ramollissement exists as a Single Lesion*, unaccompanied by any effusion of fluid into the ventricular cavities, which cases are excessively rare, and will not, I fear, permit the deduction of any general principles. The ramollissement now spoken of is remarkable in this respect, that it is rarely accompanied with a red coloration of the nervous pulp; on the contrary, the softened cerebral substance is white, of a dull pale colour, and we seldom or never find any trace of injection in the vessels. ABERCROMBIE gives one case of this kind; but we may establish it as a general rule, that red softening of the medullary central parts of the brain is a lesion excessively rare. It may attack all the three parts mentioned a while ago, or only one of them. *Ramollissement of the corpus callosum is the most rare of the three.* Softening of the septum lucidum alone is also a lesion very seldom observed in the dead body. In the considerations we have to lay before you on this part of our subject, we find ourselves compelled, contrary to custom, to depend alone on the history of particular facts, for the records of the science do not furnish a sufficient number of examples of ramollissement affecting the white central parts, to enable us to draw a general picture of this lesion. Were we to launch out into general reflections, and attempt to describe the form under an *ensemble* of symptoms, we should only run the chance of deceiving and leading you astray, for we again repeat, the records of medicine do not afford a sufficient number of facts for the deduction of general principles. We shall speak, in the first instance, of ramollissement when confined to any one part alone; we shall then consider it when affecting at one and the same time the corpus callosum, the septum lucidum, and the fornix.

First, for ramollissement confined to the thin layer of medullary substance called septum lucidum. You will find one example of this kind in M. ROSTAN'S work; a second is related in the letters of M. LALLEMAND on diseases of the brain and nerves. Now what

were the symptoms observed in these two cases? Both patients were affected with headache; one exhibited as a lesion of motility, a paralysis of one side of the body, which gradually became general, and implicated the four limbs together. In M. ROSTAN'S case, we find no mention made of paralysis; the patient was merely agitated by convulsive movements. This, you see, is analogous to what we saw before when treating of ramollissement of the hemispheres. The lesion of motility at one time manifests itself in paralysis, at another in disordered movements. In both of these two cases death arrived in the same manner; the patients fell into a state of coma, from which condition it was impossible to recover them.

Let us now turn to isolated ramollissement of the fornix, or rather of the nervous mass placed above it, the corpus callosum. We do not possess a single case of the latter, nor of the fornix alone; we must, therefore, consider them, when softened, one or other, in conjunction with the septum lucidum. What are the symptoms of ramollissement when these parts are simultaneously softened? One of the principal is headache, which is often very acute and distressing. In one case described by ABENACROMBIE, page 129, the pain in the head is mentioned as being excessively intense, and extending across the forehead from temple to temple. In another case the pain was confined entirely to the frontal region. This severe cephalalgia is sometimes the only symptom that exists for a considerable period. After a certain time, the faculty of speech becomes affected; articulation is indistinct and embarrassed, delirium now supervenes, the patient falls into a state of coma, and the disease quickly terminates in death. In one case we find dyslopia mentioned as an accompanying symptom. In the work of M. LALLEMAND, there is no question of lesions of motility; he does not seem to have observed either paralysis or convulsions—at least he does not speak of them in the case he has described.* However, in children, we sometimes observe isolated ramollissement of the fornix giving rise to functional derangement of the moving power; you will find some examples of this kind in the thesis of M. POINNET sus-

tained in 1850; but the cases published are few, and, as we have already said, we cannot, without danger of error, draw any general consequences from so limited a number of facts.

The examples of ramollissement affecting the three parts together are more numerous, though still rare; you will find two in the work of M. LALLEMAND, already alluded to, which were communicated to him by M. MARTIN-SOLON. M. SENN has also described the same lesion in his Treatise on the Acute Meningitis of Children. In many of these cases we find headache given as one of the first symptoms, but in one only does the author speak of vomiting, a symptom which so often accompanies in its origin acute inflammation of the cerebral membranes. With respect to the faculty of motion, we may notice a tetanic contraction of the muscles as a frequent symptom; this phenomenon is described as attacking various parts of the body, throwing back the head, and giving to the whole trunk a cadaveric species of stiffness. All these cases terminate in coma, more or less well-marked, which perseveres to the instant of death. These are the usual phenomena observed connected with lesions of motility. We must not forget to mention one more symptom of this affection, which has been described by M. SENN alone, as *A Phenomenon of Sensibility peculiarly characterizing Ramollissement of the Central White Parts*. This is an exalted sensibility in the integuments of the trunk. "The patient," says this author ("Recherches sur la Meningite Aiguë des Enfants," p. 88), "cannot support the slightest pressure without complaint, and frequently the pain produced by simple contact is so great, that if we can find our examination to the abdomen, we might be led to conclude the existence of acute inflammation in the peritoneum or abdominal viscera." It would seem, however, that M. SENN has exaggerated the value of this symptom; it certainly does exist in many cases of ramollissement, and even of simple meningitis, but it is not sufficient alone to characterize the former lesion, for it is frequently absent.

We now come to a set of cases in which there exists a wonderful resemblance between this ramollissement of the three central parts, and effusion of serum into the ventricular cavities, or, *Acute Hydrocephalus*. You will find a good example of this in the work of M. CHARPENTIER, of Valenciennes, on the Natural Treatment of Acute Water in the Brain, p. 43. The subject of this case was a child eleven years of age who had been ill with cough and pain in the throat for four or five days before her reception into the hospital for sick children. She died on the tenth day of the disease and, on examining the body after death, the posterior part of the fornix and corpus cal-

* Either we have taken down the name incorrectly, or M. ANDRAL has here fallen into an error. In M. LALLEMAND'S *Recherches on the Brain and its Dependencies*, t. 1, p. 184, we find the case of a woman, forty years of age, who died after a short illness; she was attacked with fever, delirium, and convulsive movements; somnolence and contraction of the limbs; the corpus callosum and fornix were transformed into a white pulp; all the other parts of the brain were sound.—*Rep. L.*

losum were found softened, without any change of colour; the cerebral substance in the rest of the brain was perfectly sound; the membranes were intact; the lateral ventricles contained only a few drops of serum, nor was any effusion found at the base of the brain. The symptoms observed in this case were, at the commencement, fever, with pain of the abdomen, and bilious vomiting, which persisted for two or three days; headache then supervened, and on the next day the child fell into a state of coma, accompanied by strabismus, and retraction of the muscles on one side of the face. In the evening of the same day the right arm became contracted and stiff, but this phenomenon was not of long continuance; it was replaced by violent contraction of the muscles of the neck, throwing the head backwards; the member which before was the seat of contraction, now became completely paralyzed, both with respect to motion and sensibility, and the patient died in a few hours. In this observation, we do not find any cause to explain the hemiplegia which attacked the patient shortly before death; the only lesion which existed was softening of the corpus callosum, the septum lucidum, and the posterior part of the fornix, and we do not know that physiologists have attributed the faculty of directing motion to any of those parts. This is all we have to say *propos* to ramollissement of the white central parts of the brain. Let us turn to the

Ramollissement of one Lobe of the Cerebellum.

Ramollissement may affect here either the median lobe, or one of the lateral lobes; we speak of softening confined to the cerebellum alone, and not coexisting with a similar affection of the cerebrum; as to softening of the median lobe, we are acquainted with only a single case in the records of medicine; it is that given by DANCÉ, in his "Mémorial on Acente Hydrocephalus" (*Archives Generales*, Janvier 1830; here the ramollissement occupied the right half of the superior almond-shaped lobe, and extended thence to the corresponding part of the mesocephale (pons &c.) This case was not attended by any special symptom whatever; the patient died in a state of coma resembling apoplexy; we must, therefore, turn to ramollissement of the lateral lobes of the cerebellum.

We do not possess the same number of facts connected with softening of the cerebellum as we do of the cerebrum; the former lesion is much more rare than the latter. Thus we have been able to collect only thirteen cases of ramollissement confined to one of the lateral lobes of the cerebellum; nine of these belong to various authors, four to myself; you will find the latter detailed in the fifth volume of the *Clinique Médicale*. Let us take a rapid view of

the symptoms which presented in these 13 cases. In the whole of these cases, except three, we find the intelligence preserved for a greater or less period from the commencement of the malady. In two examples, without having been deranged, the intellectual faculties were dull and slow. In the three exceptional cases just mentioned, the disease commenced, suddenly, by a loss of consciousness, as if the individual was seized with a violent effusion of blood into the cerebral hemispheres. The faculty of speech also remained intact in all the thirteen cases except two. In the one related by M. MONROU, the speech was simply difficult, but the patient was still able to make himself understood. In the other, which belongs to M. LALLEMANN, the power of speaking was completely lost. This is all we have to remark in connection with lesions of intelligence; they are various, but, as you see, of slight importance, except in those violent cases where it is nearly impossible to distinguish ramollissement from hemorrhage of the brain. Now for

Lesions of Movement.

These are observed infinitely more frequently: thus in our thirteen cases we find twelve in which the motility was more or less modified, and perhaps even in the thirteenth this took place also; at least it is impossible to say that no lesion of motility existed, for the author (M. DANCÉ, "Mémorial de Med. Milit." t. 22, p. 379) merely states that the patient fell into a state of coma, without mentioning whether the limbs were paralyzed or not; indeed, the whole history of this case is imperfect; even the nature of the lesion in the cerebellum is too vaguely described. We are, therefore, induced to lay aside the case given by M. DANCÉ, and conclude that in all cases of ramollissement situated in one of the cerebellar lobes, some lesion of motility exists.

But what constitutes this lesion? What is its nature? Under what form do we observe it? These are questions which we now proceed to answer. In one case we find a constant agitation of the body; the limbs were neither contracted nor paralyzed, phenomena so often observed in ramollissement of the cerebral hemispheres, but affected with a convulsive agitation occupying equally the upper and lower extremities on both sides of the body. In the eleven cases which remain we find six accompanied by contraction and stiffness of the limbs; five of which gave rise to paralysis, either with or without contracture.* We have now to ask

* This enumeration differs slightly from that given by M. Andral in his clinique, where he describes two cases as attended with convulsive agitation, and ten with paralysis or contracture. As to the case,

what I know is going on on every side, I feel a degree of repugnance at such subjects, and would almost willingly allow the shafts of malevolence, envy, and detraction, to expend their harmless force on the surrounding elements. I pity the poor creatures who have no other means of obtaining a livelihood. They have not the legitimate instruments of advancement within their reach,—industry and intellect,—and what can they do? They must exist. They are compelled to use the only weapons in their power.

I have still a few words to say on scalded glottitis. There are certain cases of this accident in which the calomel treatment will not be sufficient, because death may occur before the system is made to feel the action of the remedy. There are, then,

Certain Cases in which Bronchotomy must be resorted to

for the purpose of gaining time. Such was likely to have happened in the case which has just occurred. I proposed, adopted, and succeeded in the performance of this operation, in these tender subjects, fifteen years ago, when I need not tell you that I was a very young practitioner. Indeed it was by means of this operation that I first endeavoured to snatch the interesting but desecrated subjects of this cruel accident from the grasp of death. Soon after the publication of my first case, Dr. Marshall Hall, a gentleman personally quite unknown to me, but for whom I entertain, from his writings, the highest respect, proposed the performance of the same operation in the same cases, and gave one in which it had been employed, unsuccessfully, however; and it is only fair to state, that although my case preceded the publication of his essay, I cannot have the slightest doubt that his proposal originated in his own mind, without any knowledge whatever of what had been done by me. There are, therefore, certain cases of scalded glottitis in which you must perform bronchotomy, to gain time. But, upon this point I have to warn you of a mistake into which many have fallen, and daily fall. The operation will seldom be alone sufficient, and if you trust to it alone, you will often lose your patient. The inflammation excited by the injury will, notwithstanding that relief may be afforded by the operation, extend to the bronchial tubes, and the patient will die, not perhaps so soon as if the operation had not been performed, but death will, most probably, follow. Bear, therefore, this important fact in mind. View the operation only as a means of gaining time. Pursue an efficient

Calomel Treatment after the Operation,

modified, however, for, having more time, you are not called upon to employ doses so large, or to repeat them so often, though I believe

the remedy to be so rapid, as rapidly as possible, in such action. I deem it the more necessary to urge this point upon you, as you will not find that any of those persons who have lately spoken of the operation, or recommended its use in these cases, have spoken of the necessity of employing, at the same time, the influence of mercurial action, nor have they even at all alluded to the practice. This, if anything were necessary, would, of itself, afford ample to those detractors who would insinuate, that the calomel treatment of these cases has been long well known, and is a generally employed mode of practice. *The insufficiency of the operation unassisted by the calomel treatment is pointed out by the case of Eliza Butler, which some time since occurred here.* The notes of this case I hold in my hand, and Mr. Cullen, who furnished them to me, has promised to insert them for your perusal in the case-book. See Case 1. I hold also in my hand, notes of another case, the dissection of which I witnessed, and which demonstrates the same truth. These I shall leave on the table also for your information, as time will not now permit me to read them over to you. (See Case 2.) Let me remark, that both cases afford highly important information. They not only show, as I have just said, that the operation cannot be depended on without the mercurial treatment be conjoined, but they further demonstrate the

Manner in which the Injury kills :

the extent and form of the lesion which it causes, as well as the nature and the order of the symptoms which it produces, with all of which I have made you acquainted in former lectures. (See Lecture in LANCET, 1834, page 677.)

I have been informed by the apothecary, that some time ago a child was brought to the Dispensary, cold, comatose, and labouring under excessive dyspnoea, the respiration being exceedingly laborious, and accompanied by a loud sonorous rale. On opening the mouth by force to inspect the fauces, an abscess was broken, and a quantity of whey-like pus discharged. The breathing was immediately relieved, and the child recovered. It was stated by the parent of the child, that it had some days before attempted to take a drink from the spout of a tea-kettle containing boiling water. These are interesting facts for you to know. They enlarge our views of the pathology of this injury, and show, that although a child may weather the more immediate effects of the lesion, a suppurative, or slower morbid action may set in, which may be equally destructive. This case also demonstrates, that death may be caused by the mechanical obstruction occasioned in the throat, although no inflammatory action may have extended to the lungs or chest;

for there can be no doubt that a child had not gotten to the point of having sunk; and as the relief afforded by the bursting of the abscess was followed by rapid recovery, it is evident that the injury had not produced much effect on the chest.

Treatment, and its Occasional Failure.

When you reflect on the tender objects of these injuries; on the delicate state of health in which the children of the poor of the age of those in whom the injury almost always and necessarily occurs; when you consider the importance of the injured part, and the nature of the operation of bronchotomy in an infant, you will not be surprised to find that success will sometimes fly from the best-directed efforts. These remarks I make in consequence of having heard that it was excitingly, but absurdly said, on one occasion, "Here is a case in which the operation has been performed, here is a case in which calomel has been used, and yet here do we find that the child's life has not been saved." Is it not absurd to expect uniform success in such cases? But, I can say that the success will, in properly-treated cases, be almost constant. It will leave no room whatever to doubt the propriety of the measures proposed. I have lost one case, and only one, out of very many indeed, out of, at least, upwards of a dozen, and I think I should not have lost that one if the parents of the child had acted with discretion.

A case has been mentioned to me where the child, notwithstanding every care, happened, after the calomel treatment and the operation had been conjointly employed, into a state of feverish excitement, which gradually led to great exhaustion and sinking. This I can well believe, I can also easily conceive that after such attacks, a state of general delicacy of health may often take place, the management of which may require great judgment.

Whenever the accident in question occurs in your practice, lose no time in submitting your patient to mercurial action,—you may, if you please, assist it by leeches applied about the larynx. But do not let the apparent absence of danger, or of alarming symptoms, induce you to postpone, even for an hour, the most efficient line of practice which you can adopt: for these cases are often most treacherous. All appearance of serious injury may be absent for hours after the accident, and then the most alarming symptoms will set in with great rapidity. A child often suffers so little in appearance, after the moment of alarm has passed by, that the parent is often lulled into a false security, and believes that no mischief has been done, unless perhaps some little excoriation or irritation of the mouth. If the mercurial treatment have been early commenced and properly carried on, your

success, without an operation, will be almost certain. If, however, you have not seen the case until dangerous or distressing symptoms have set in, you are first to consider, whether the state of your patient be such, that there exists a rational hope that the disease may be overtaken by the action of the remedy. If you think so, you administer, without having recourse to the operation of bronchotomy, two grains of calomel every half hour or hour, until relief be obtained. You should combine each dose of calomel with half a minim of tincture of opium, and as soon as symptoms of relief appear, the dose may be diminished, and the interval increased: but the remedy should be persisted in until all symptoms of distress are removed. On the other hand, if you find that the symptoms are so severe, and are becoming so rapidly worse, as to lead you to fear that dissolution may take place before a state of sufficient mercurial action can be excited, you must have recourse at once to the operation of bronchotomy, which will gain time for you, and afterwards pursue the mercurial treatment until you have secured the safety of your patient. These directions, if adopted, will enable you to steer these cases almost uniformly through their first danger; but to bring them to a full and happy termination, you must not lose sight of them until their tender systems have completely recovered from the shock caused by both injury and treatment.

Abstract of Cases alluded to.

Case 1.—Eliza Butler, aged three years, was brought to the hospital at nine o'clock in the morning of the 14th of last July. At ten o'clock the preceding night she attempted to take a drink from the spout of a tea-kettle, which had been just removed boiling from the fire. Shortly after the accident she became dozy, and slept, and some hours after got wheezing. On admission she was warm, her pulse too quick to be counted. She had excessive dyspnoea. Respiration sixty in a minute and sonorous. Tracheal rattle prevented auscultation from being satisfactory. Lips and face rather livid; eyes languid; she was listless and drowsy; drank freely; her tongue and fauces appeared white and scalded. Four grains of calomel were given; and at eleven o'clock, that is, two hours after admission, tracheotomy being decided on, an incision was made with a scalpel along the mesial line. There was scarcely any bleeding. The trachea was exposed with a blunt knife, and by the assistance of a hook was drawn forwards, when a circular piece was cut out with a pair of scissors. There was then slight bleeding, which stopped in a few minutes.

Respiration was immediately carried on through the wound. She seemed rather

heavy and insensible all day; there were, however, remarkable changes. At five o'clock she appeared better, more sensible, and drank freely. But at twelve o'clock, midnight, there was stupor, intense bronchitis, mucous rattle in the anterior part of chest. At three o'clock, a.m., coma, dilated pupils, convulsion of face; tonic contraction of right arm; pulse imperceptible; intense heat of skin; and she died at eight. One dose of calomel (grs. ij) was given after the operation, but it was not persevered in.

Autopsia.—Epiglottis and upper rima thickened, white, and shrivelled. Those appearances evidently successive to oedema. Larynx, from this part to artificial aperture, healthy. The wound of sufficient size, and unobstructed. Between wound and ramifications of bronchia, tenacious lymph effused. Bronchial membrane exceedingly vascular. The more minute bronchial ramifications clogged with tenacious mucus. The anterior part, only, of the lungs, crepitate. The posterior and upper portions are in a state of red hepatization. Lungs are exceedingly solid. When cut and squeezed, some sanguineolated mucus is forced out from the air-tubes. The hepatized portions float in water; no part has gone on to purulent infiltration. Oesophagus and stomach perfectly healthy. Veins and sinuses of brain injected. One or two ounces of serum in ventricles.

Case 2.—A healthy male child, aged between three and four years, attempted to take a drink from the spout of a tea-kettle containing boiling water. Whether it was that the child had not felt much pain, or that fear had prevented him from making complaints, it so happened that he appeared, at the time, not at all injured; he was soon after put to bed, and his bed being in the room in which his mother sat, she had an opportunity of observing that he went to sleep in his usual manner. But, in about three hours after, and while still asleep, his breathing became so much affected with wheezing as to arouse the attention of his mother, and subsequently to induce her to take him up and carry him to a surgeon. When he was seen by the surgeon, eight hours after the accident, the breathing was fifty-six in a minute, difficult and sonorous. Inspiration seemed to require a great effort, and to be much longer in its performance than expiration. The pulse was upwards of 130; the surface of the body very warm; the face flushed. He did not seem to complain of anything, yet the tongue and lips were covered with a white pulpy matter, which could be rubbed off in layers, when a red surface was exposed. Much distress was produced on passing the finger into the isthmus of the fauces, which felt tumid and pulpy, but did not afford any sensation as if there was a state of vesication. Leeches,

and cups, were employed, but the state of the child was rapidly progressing. Fourteen hours after the accident, the child lay on its back, listless; its respiration reached upwards of 60; its pulse could not be counted distinctly, partly from its rapidity, and partly from some irregularity in its returns; his countenance flushed, and his skin became very hot. The operation of bronchotomy was now performed. Immediate relief was afforded; he seemed roused from his insensibility, opened his eyes, sat up, and cried. Indeed, for a time the amendment was so great as to lead to a hope of recovery. In the course, however, of some hours the breathing became worse, and his face affected by convulsive twitches. These were followed by more general convulsions, and he was in one of these carried off, about twenty-four hours after the operation.

Autopsia.—The character of the *cadaver* was such as to make an impression on the mind that the child had been, at the moment of the injury, in fine health. Neither the lips nor the mouth presented an appearance as if they had been much injured by the boiling water. The wound over the trachea was ample and patulous, and the laminae of tissues through which it had been made were agglutinated to either side. All the soft parts exterior to the trachea were sound, and free from inflammation. The wound in the trachea itself appeared unnecessarily large, and this tube, on the site of the wound, was greatly narrowed. From this point it gradually acquired, both upwards and downwards, its natural dimensions. The narrowing of the tube at the site of the wound, arose evidently from the removal of a large portion of the elastic structure of the pipe; and had the child recovered, I think it very likely that some permanent inconvenience might have resulted from this narrowing. Hence, I would advise that on occasions in which bronchotomy is required in children, no more of this tube should be removed than is indispensable. The cavity of the trachea was full of a reddish mucus, and its lining membrane, the vascularity of which was greatly increased, was covered, in the neighbourhood of the wound, and from thus to the glottis, by a stratum of lymph. The glottis, epiglottis, and the surrounding parts, to the extent of an inch, were greatly thickened, from submucous effusion. There was not, however, the slightest appearance of vesication, or as if any bullic had been formed and had burst. The epiglottis was shrivelled, so as to form a kind of tubercle which could, badly indeed, perform the action of a valve. This explained the fact, that during the life of the child, and subsequent to the operation, the drink had, as I am informed, constantly escaped from the wound. On portions of the surface of the epiglottis, and of

the surrounding tissue, where it was a more elevated gray-looking substance, which seemed somewhat like stratified lymph, yet could not be rubbed off. Hence, I concluded that it was only the lining mucous membrane of these parts, altered very much in its structure.

There seemed to be a slightly emphysematous state of the upper portions of the left lung; and parts of both lungs, particularly on their posterior aspect, were engorged with blood, were very livid, and solid, yet these parts did not sink in water. When a section was made of the denser portions of the lungs, puriform mucus could be expressed, in quantity, from the bronchia of the cut surface, and the intermediate parts exuded, at the same time, a quantity of a dark, livid, or bloody-like fluid. The remainder of the thoracic viscera, and those of the abdominal cavity, the lining membrane of the stomach included, were free from disease.

The vessels of the brain and of all its coverings were gorged with blood. There was a considerable quantity of a clear serum in the ventricles, and when the brain, which was very firm for the age of the subject, was removed, there was found in the base of the cranium, and round the spinal marrow, a large quantity of reddish serum.

DESCRIPTION OF AN

HERMAPHRODITE ORANG-OUTANG

LATELY LIVING IN PHILADELPHIA.

This animal had black, thick, woolly, and frizzled hair, covering all parts of the body with the exception of the palms, the face, and the ears. Its skin was black, and it had nails on all the fingers. The orbits of the eyes were prominent, the arms very long. It had no cheek pouches, nor any tail, nor a guttural sac, and there were rudiments, only, of a gluteous buttocks. The nose was more prominent, and the facial angle more elevated, than in the *simia satyrus* of Linnaeus. Its height from the vertex to the

heel was two feet two inches. Its arms were 15½ inches long, the hand and fingers 5½ inches, the lower extremities 11 inches, the foot was 4½ inches long, the head and neck 11½ inches long.

This interesting animal was imported into New York, from the island of Borneo; and at its death it was said to be rather less than two years of age. Each jaw contained twelve teeth; three molars, one canine, and two incisors, on each side. When standing erect, the fingers of the forehand nearly touched the ground; when advancing on a plane surface, he voluntarily assumed the erect attitude; he balanced himself with his long arms, on the slack rope, and climbed with the greatest agility; when he retired to sleep, he assumed a recumbent posture; he displayed great fondness for fruits of all descriptions, but particularly for grapes, and he possessed all the docility and intelligence which is characteristic of the oranges. He died of a diarrhoea from excessive indulgence in fruits.

The orang genus has already been increased from one to six species. The present specimen differs from all the others hitherto described; it evidently pertains to the Gibbon family, or the long-armed oranges,* and differs from the others in being of a universal black colour, in the facial line being less inclined, in the absence of the circle of gray hairs around the face, in the rudimentary state of the ischiatic callosities, and, with the exception of the active Gibbon, in the absence of the guttural sacs.

On the death of the animal there were found general adhesions of the peritoneum, the omentum, and the intestines. The glands of the mesentery were very much enlarged. There were white eruptions, or, rather, ulcerated tubercles, on the peritoneum, such as are observed occasionally in scrofulous subjects, and inflammation of the mucous coat of the stomach, and the intestinum rectum.

Orangs have, occasionally, been dissected, and minute and laboured descriptions of their anatomy published. The present individual displayed remarkable peculiarities. The ligamentum rotundum was very strong; the liver resembled the human, having the same number of lobes, &c. The appendix vermiformis was very large; the contents of the thorax displayed a close analogy to those of the human being. The ventricles of Morgagni were rather large, although not communicating with a sac in the throat, as in the *simia satyrus* and some monkeys; the

* The type of which is the *Simia lar*, (Linn.) to which are added, first, the little Gibbon, or *Orang* varic of Cuvier; second, the Stunang, or *S. Syndactylus* of Rafines; and, third, the Active Gibbon, or Wou-won of DuRoi and F. Cuvier. Should I be right in supposing that the above details offer specific differences, the animal may properly be named *Simia Concolor*.

sternum was composed of only two pieces, like that bone in man, in which respect it differs from the simia with tails. There were twenty-five rings to the trachea, fourteen ribs on each side, fourteen dorsal vertebrae, seven cervical, five lumbar, five sacral, and five coccygeal; but the most remarkable peculiarity remains to be noticed; the subject proved to be a complete hermaphrodite.

Hermaphroditism, that is to say, individuals uniting in themselves the means of reproduction, without the concurrence of other individuals of their own species, appears to be in some sort a vegetable attribute, as among plants the class Dioecia (Linnaeus) is the only one not hermaphrodite. The nearer the animal approaches to the vegetable kingdom, the more frequent and complete are the instances of hermaphroditism. This is of two distinct kinds: in the one it is absolute, the animal possessing within itself the powers of reproduction, as is instanced in the bivalve shells (the oyster for instance), in some of the multivalves (as the chiton), and in the zoophytes, the holothuria, &c.; whilst in univalve shells, on the contrary, such as the helix, limnea, planorbis, &c., although they unite the two sexes, yet the union of two individuals is necessary to fecundation. The common garden-snail is a familiar example. Animals of this description are properly termed "androgynous."

The disposition, then, to hermaphroditism is more rare as we advance in the scale of perfection, or, rather, to a more complex organization. Those cases which are said to have occurred in the higher orders of animals, may, with few exceptions, be attributed to mal-conformation of the genital organs, and to an admixture of the two sexes, which, according to the observations of Sir E. Home and Mr. John Hunter, are of more frequent occurrence in the bull than in any other of the mammifera; but in no instance have these authors found the assemblage of the organs of both sexes complete, some or other of the organs being absent, or existing only in a rudimentary state. The case which most nearly approaches in perfection to the subject of the present description, is that detailed by Mascagni in the "Bulletin de la Faculté de Médecine," for 1811, p. 176,* where he describes a bull, with all the male organs, and with ovaries, uterus, and vagina, but in place of a vulva, the vagina had its orifice in the urethra. There is also another case, somewhat similar, described in the *Med. Repository*, No. 45, of a human individual, in Lisbon, uniting both sexes in apparently great perfection. The subject was twenty-one years of age, was twice pregnant, and aborted at the third and fifth months. It is true that although the penis and the testicle existed, the latter with their excretory

ducts, were not opened anatomically. For a more detailed account of this individual, vide "Dictionnaire des Sciences Médicales," art. "Cas Rares." The above observations will at least demonstrate the possibility of the occurrence of complete hermaphrodites, even in the highest class of animals.

The specimen which forms the subject of the present description will furnish us, perhaps, with the nearest approach to a complete union of the sexes in the same individual which has been detailed; and is the only instance, so far as we have observed, of a circumstance of this kind occurring in the monkey race. In the present instance the penis was about one inch in length, subject to erections, and terminated, as usual, in a glans, but imperforate, a deep groove on the inferior surface serving as a rudimentary urethra. This groove extended about two-thirds of the length of the penis, the remaining portion being covered with a thin, cuticular, diaphanous membrane, which also closed the external orifice of the vagina, being extended across the vulva. The vagina was rather large, and displayed transverse striæ. Remains of the nymphæ and the labia externa were visible; the meatus urinarius opened beneath the pubis into the vagina; the urine must have been directed along the groove of the penis by the membrane obstructing the orifice of the vagina. The os tincæ was surrounded by small globular glands, the orifice and cervix admitting a large probe into the cavity of the uterus, which organ appeared to be perfect, with all its appendages; the round and broad ligaments, together with well-pronounced ovaries, were all *in situ*.* The scrotum was divided, consisting of a sac on each side of the labia externa, at the base of the penis, covered with hair. The testicles lay beneath the skin of the groin, about two inches from the symphysis pubis, obliquely outwards and upwards. They appeared to be perfectly formed, with the epididymis &c. The most accurate examination could not discover vesiculæ seminales, but an opening into the vagina, above the meatus urinarius, appeared to be the orifice of the vas deferens. The testicles were unfortunately separated from the body, during the process of skinning.

Admitting what in reality appeared to be the fact, that all the essential organs of both sexes were perfect in this individual, had the subject lived to adult age, most interesting results might have been elicited. Could not the animal have been impregnated by the male individual, by rupturing the membrane closing the vulva? Or, by mastur-

* The male and female organs of generation were, in this animal, so completely perfected as could have been participated in so young an individual, and resembled those of other individuals of a similar age. Minute ova were visible in the ovaries.

bation, might not have occurred, if the animal had not inserted itself, by this means, among the testicles to discharge their seminal liquor into its own vagina? The imperfection of the urethra most probably would have prevented the animal from ejecting the semen into the vagina of another individual. The subject whilst living always passed for a male. Had an instance of as complete a nature

occurred in the human subject, it might have occasioned great difficulties in a case of legal medicine. Dr. Charles Pickering and others assisted at the dissection. The subjoined are engraved from accurate drawings of the anatomical parts, in a recent state, of the natural size, taken by Dr. Morton. The head, page 963, was drawn by Dr. R. M. Bird.

CASE OF INTESTINAL CONCRETION, OR, ENTEROLITHUS.

To the Editor of THE LANCET.

SIR,—I am induced to send you a short account of a case of intestinal concretion, or enterolithus, with some observations on the subject, because the attention of the profession, either in public or private practice, is seldom called to this form of disease. I remain, Sir, your obedient servant,

J. L. IKIN, Surgeon.

Halifax, Yorkshire, March 12, 1836.

A short time ago I was requested to see a man in the country, an under-gardener by occupation, æt. 34, of a naturally robust constitution, who had always enjoyed excellent health, until within four or five months previous to the time at which I was consulted. His symptoms at this period were, pain in the lower part of the abdomen, more particularly in the right iliac region, sometimes relieved by pressure, at other times aggravated by it, which had continued for several months, though varying constantly in its degree of violence; along with this there was an irregular state of the bowels, costiveness and purging alternating;

the discharge often watery, tinged with blood, and attended with tenesmus.

His digestive organs were much impaired, having a furred tongue, dry skin, frequent thirst, headache, bad appetite, loss of strength. His pulse was, however, nearly natural, and there was little or no fever. His general appearance had undergone a considerable change within the last three or four months, and his strength had failed him to such a degree that he could only attend to the lighter duties of his occupation. As the bowels were in this irregular state, and as the pain was not at this time increased on pressure, nor such as indicated blood-letting, I ordered him a brisk purge of calomel and jalap in the evening, to be followed up with a draught of sulphate of magnesia and rhubarb in the morning. He was directed to remain quiet for a day, and was put on low diet.

The effect of this medicine was to give considerable relief, though still the sensation of pain and weight in the abdomen was not removed; the pain, however, was now felt most in the left iliac region. From the unhealthy and indurated state of his feces I began to suspect that an accumulation of feces was the irritating cause, and produced his ailments; I therefore, after an interval of forty-eight hours, repeated the purge of calomel and jalap, adding only a little pulvis cinnamomi compos. to relieve the griping of which he had complained, and continued the cathartic draught. On visiting him the day but one after, I found his symptoms entirely relieved and my patient in high spirits; he informed me that his sufferings had been very great for four or five hours previous to and during his last evacuation, but that now he had succeeded in dislodging the cause of his illness. Having distinctly felt a hard substance pressing on the parts, whilst straining at stool, only an inch or two above the anus, he had, after many attempts, and intense pain, removed it by aid of a wooden scoop. Only a slight soreness at the lower part of the abdomen, and in the rectum, was now experienced. To allay this irritation of the mucous membrane I prescribed an emollient clyster, mucilaginous drinks, &c., so that in a few days he was able to return to his usual diet and employment.

Observations.—On examining the substance expelled, it appeared at first sight to be nothing but a large indurated mass of feces, in the shape of a ball, and as large as the fist, but when it had been repeatedly washed, a most curious-shaped intestinal concretion was found in the centre, resembling somewhat, in form, the tuberos root of an orchis, only having six or seven tubercles or excrescences instead of two. The following diagram may serve to give an idea of it, the tubercles taking their origin from

a common centre. In the fecal matter was removed, it weighed rather less than an ounce. Its colour resembled that of rhubarb; the woody fibres were distinct, and mixed with calcareous deposits, both externally and internally. On cutting into it, the nucleus had more the appearance of a cherry-stone than anything else. There was a cavity of about the size found in those stones. A calcareous deposit of phosphate of lime surrounded it. The man felt convinced, that if the substance had been allowed to remain, it would have eaten its way through his abdomen, or permanently have stopped up the passage. I told him, that perhaps a cherry-tree would have grown from his body, like that which grew from the forehead of Munchausen's stag, and that had this happened, he would have become the most extraordinary gardener in the world. On more minutely examining this concretion, it was found to consist principally of woody fibre, and of a great quantity of a peculiar substance like *amidon*,† or the skin which covers the horns of deer when they first shoot; it has the appearance of soft, velvety, brown, spongy network, with short spicula. It is insoluble in water, partially soluble in alcohol, and blackens with sulphuric acid, burns with a slight flame, emits an odour of woody fibre, or tinder (of which it is a description), and heat reduces it to a charcoal. The calcareous deposits I found to consist of phosphate of lime, ammonia, and magnesia, the presence of which I detected, by adopting the process mentioned by Dr. Turner in the 24th vol. of the *Edinb. Med. and Surg. Journal*, where there is a case of intestinal concretion related by Mr. Tortet, with Dr. Turner's analysis. In the case before us, I attribute the formation of the concretion to the torpid state of the bowels, and to the swallowing of some indigestible matter, as a cherry-stone, or some fruit stone of that description.

Had I not persevered in the use of brisk purgatives, the result might have been most untoward; or had I mistaken the symptoms for those of inflammation of the mucous membrane, and ordered leeching, counter-irritants, and mild laxatives *only*, the exciting cause of derangement would not have been removed; or suppose I had attributed the causes of his sufferings to spasm, or nervous irritability, and had ordered a strong

* The sketch was not sufficiently perfect to allow an engraving to be made from it, but the section has the appearance of a rosette of riband, with six bows, the centre being an inch in diameter, and the bows each somewhat less in length; the diameter of the whole is about two and a half inches.—Ed. L.

† A variety of the *belius ignarius*, called "spunk," or "German bladder."

antispasmodic, or, ~~if necessary~~, before employing purgatives, the consequences might have been still worse than in the former case. These considerations are worthy of the attention of practitioners, and as a young one, I thought myself fortunate in the happy termination of the case. It appeared from the symptoms that the effect of the first dose of the medicine was to remove the concretion and accumulated mass of feces from the right iliac region, or from the caecum and ilio-caecal valve, and the left iliac region, when the repetition of the purge caused the enemy to retreat to the back door, and that the sigmoid flexure of the colon and curves of the rectum obviated in some measure its free passage, producing the sensation of pain so acutely felt at this period.

The rarity of these cases and the practical nature of the subject must plead my excuse for requesting a little more room in your valuable Journal.

Intestinal concretions are not common in the human body, though several cases are recorded in Munro's work on the Morbid Anatomy of the Stomach, Gullet, and Intestines, in Good's Study of Medicine, in the *Edinburgh Journal*, in Andral's work, and in the works of other foreign authors. In ruminating animals they are often observed, especially in those whose food consists of husks, beads of oats, &c., as in millers' horses. The intestinal calculus has been found occasionally to resemble the bezoar,* found chiefly in the camel and the goat, and formerly used in Holland and Portugal as an alexipharmic. According to Drs. Fourcroy, Vauquelin, and Berthollet, eight kinds of bezoars have been described, those consisting of,—1st, Super-phosphate of lime; 2nd, phosphate of magnesia; 3rd, phosphate of ammonia and magnesia; 4th, biliary; 5th, resinous; 6th, fungoid; 7th, hairy; 8th, ligniform.

Dr. Good describes only three kinds of enterolithus, viz., bezoardus, calculus, and scybalum. As almost all animals are endowed with the power of separating and secreting lime and other earths from the blood for particular purposes, such as that of forming a shell, a covering for insects, &c., so, in a morbid state of the system, generally, this secretion often takes place in abundance, and is poured forth into cavities where its accumulation and crystallization must be attended with mischief. The three varieties of true enterolithus are described as taking their origin in the following manner (See Copeland's "Dictionary") :—1st. Those whose nuclei have been formed from inspissated bile, gall-stones, &c., to which saline and animal matter have at-

tached themselves. 2ndly. Those having nuclei consisting of foreign bodies, such as flint-stones, seeds, husks, fragments of bone, around which the alimentary matter has collected and crystallized. 3rdly. Those which are formed entirely in the alimentary canal, and which are more or less homogeneous, and have no distinct nuclei.

The present case seems to belong to the second class. Concretions are found also in the intestines of persons who are in the habit of taking large doses of magnesia and chalk. Adipocercous and fatty concretions are occasionally formed. Dr. Elliotson in his valuable lectures, and in some of his papers, narrates cases of this description.

The morbid changes produced by these alvine concretions as described by Munro in the work previously alluded to, are either the formation of a sac, constrictions of the bowel, adhesions of the concretion to the inner coat of the intestine, or ulceration of the parts in which they are lodged, &c. The treatment which has been recommended may be divided into three modes, viz., purging, dissolution, and operation. Purging is certainly the best and most likely to succeed, provided the concretion is of limited size. Treatment by dissolution holds out a poor chance of success. That by operation, is a most formidable proceeding, either in adopting Munro's method, or that of M. Tortet; the former directs us to cut down upon the foreign body, in the space between the 12th rib, in the upper margin of the os ilium, or on that part where the peritoneal covering is deficient, then to make a hole in the colon, feel for the calculus, extract with the forceps, &c. The danger of this operation is evident enough, and, besides, how are we to be sure that the concretion will be found in the spot corresponding with the external incision? Mr. Tortet recommends to cut immediately upon the foreign body, supposing it can be distinctly felt through the skin, on the strength of the idea that the danger arising from wounds of the peritoneum and the exposure of the viscera to the contact of air has been exaggerated.

This operation might certainly be practised with a chance of success.

Illustrations of the Elementary Forms of Diseases. By R. CARSWELL, M.D. Fasciculi 2—9. London. Longman. 4to. 1835-6.

SINCE we reviewed the first fasciculus of Dr. Carswell's work, eight more parts have appeared, the second and third illustrative of carcinoma; the fourth of melanoma; the fifth of softening; the sixth of hemorrhage; the seventh of mortification; the eighth of

* From the German compound "pall-sch," or "pall-scher," corrupted into "bed-zohr," or "bezoar," and translated "depeffens tumorem."

pus; the ninth of hypertrophy. Each fasciculus presents a comprehensive view of one of the morbid conditions or products which Dr. Carswell has denominated "elementary forms of disease," because out of them, or their combinations, every organic disease, every appreciable anatomical lesion, is compounded. Several of the facts which are stated in the different fasciculi are new; and the manner in which they are generalized and explained is always ingenious; but it is the clear and logical manner in which all the doctrines of morbid anatomy are announced, and the beautiful accuracy with which every morbid form and shade is delineated, which give the chief character to this work, which is well calculated, as we at first predicated, to diffuse the important discoveries made on the continent and in this country, to put them at once in the possession of every practitioner, and so to advance, more than any other recent publication, the progress of practical medicine.

We shall only notice the last and ninth fasciculus, which treats of hypertrophy,—"the consequences of an excess of the nutritive functions," and not, as has been supposed, "the consequence of an accumulation of the nutritive materials, from a diminished exercise of the act of decomposition."

Hypertrophy is sometimes *congenital*; at other times there is in the body a general tendency to an increased but imperfect development of various organs and tissues of the body, such as is observed in persons of a scrofulous constitution, where "the liver, the bones, the lymphatic glands, sometimes the brain, and, frequently, the upper lip, are, more or less, obviously enlarged."

The development of the adipose tissue is at times carried to an enormous extent under the influence of hereditary disposition, but more frequently under the influence of *gourmanderie*, leisure, and supersaturation of the system with aliment, as was remarkably exemplified in the ancient race of *corporators*, and the dignitaries of some Christian churches. Among the local causes of hypertrophy, Dr. Carswell enumerates "frequent and increased action of an organ in the normal exercise of its function." It is this kind of hypertrophy which occurs in the voluntary muscles, more especially in those of the extremities; but in the blacksmith's arm, or in the leg of a Taglioni or

a Vestrali, or other forms that terminate as well, the hypertrophy is not to be considered pathological. Notwithstanding this reservation, Dr. Carswell has remarked that the "superior extremities of celebrated dancers suffer, and, when compared with the inferior, almost appear to be emaciated, while the legs of the *dragman* are sometimes so slender, that they seem hardly to possess sufficient strength to sustain the weight of his broad chest and brawny shoulders.

A more important variety of this form of hypertrophy occurs in some involuntary muscles and double organs. Great hypertrophy of the heart is by no means uncommon, and is attributable only to excessive action, induced through the agency of certain diseased states of other organs, particularly of the brain and nervous system. The increase of bulk in one lung, or in one kidney, when the function of the other is suppressed, affords an interesting example of hypertrophy from a physiological increase of function, called into operation by the wants of the economy. The increased development of arteries and veins for carrying on a collateral circulation, the enlargement of the uterus and of the mammae in pregnancy, and, perhaps, the augmented bulk of one cerebral hemisphere, when the other is atrophied, may be legitimately referred to the same kind of hypertrophy.

The second cause of hypertrophy is "the existence of a *mechanical obstacle* to the accomplishment of the function of an organ." The most frequent cause of hypertrophy of the heart, the stomach, the bladder, and the biliary ducts, is some contraction or obstruction in the *orifices* of those organs, by which their muscular parietes are excited to increased action, and are, consequently, from the reason above stated, augmented in volume.

The *long-continued influence of a morbid stimulus*, is the most general cause of hypertrophy:—

"A state of irritation or chronic inflammation, is by far the most frequent cause of hypertrophy of the *mucous*, the *cutaneous*, the *cellular*, the *fibrous*, and the *osseous* tissues, and the *glandular organs*; nor is it an unfrequent occurrence in the *involuntary muscles*, besides being occasionally met with in the *brain* and the *nerves*, and their *ganglia*."

Dr. Carswell has made some interesting observations on the state of the vessels in

aneurysms, and the formation of cardiac aneurysms.

The *first plate* in the fasciculus which we are noticing, shows hypertrophy of the bronchi, the circular fibres of which are enlarged, and form transverse bands. Other figures represent emphysema, in which the dilated cells vary from the size of a pin's head to that of a cherry or a walnut. The *second plate* represents various forms of cardiac hypertrophy. Figs. 1, 2, 3, of the *third plate* represent the morbid appearances which precede and accompany the formation of aneurysmal dilatation of the heart:—

"The serous membrane lining the internal surface of the ventricle, presents within a circumscribed space, varying from a quarter of an inch to one or two inches in breadth, or even from one half to two-thirds of its entire extent, a pale straw colour; it has become opaque, is closely united to the cellular tissue beneath it, which presents the same colour, and is considerably thickened. Occupying the situation in which these changes are perceived, and sometimes nearly to the same extent, are one, two, three, or more depressions, cavities, or sacs. These are lined by the serous membrane and cellular tissue."

Fig. 4 presents a section of the tibia, with circumscribed bony enlargement or node. Traces of the external wall of the tibia are still observable, showing that the new osseous deposit took place on the *inner surface of the periosteum*.

The *fourth plate* represents aneurysmal and varicose dilatations of the arteries; also dilatation of the lymphatics and of the urethra. Fig. 2 is an example of aneurysmal dilatations, which existed in all the arteries of the body, varying from the size of a hemp-seed to that of a large pea. Fig. 6 represents a dilatation of the urethra filled by a large stone. Although the sound had been frequently introduced, the presence of this stone had never been detected, "probably from the situation of the dilatation in the inferior surface of the penis, and the stone not projecting into the urethra." The patient was treated for varicocele in the *Hôtel Dieu of Paris*.

The following is a very remarkable case of dilatation of the lymphatics in a young man of about 26 years of age:—

"My friend, M. Amussat of Paris, was called to the patient, who the day before had been seized with severe pain in the ab-

domen, followed by frequent vomiting. These symptoms, and the presence of two swellings, one in each groin, nearly as large as an orange, left no doubt that the patient was labouring under the effects of strangulated hernia, but the state of prostration was such that reduction by an operation was not attempted. On examining the patient after death, the only remarkable circumstance observed was, enormous dilatation of the lymphatics from both groins upwards, including the thoracic duct. The two swellings situated in the groin, and which at an early age of the patient had been treated as a case of *double hernia* (for we afterwards learned that he had worn a double truss from his boyhood), were found to be produced by great dilatation of the lymphatics of the inguinal glands. When cut into, instead of having a compact structure, they presented the appearance of a coarse sponge, from the size of all these vessels being increased, the most of them presenting from one to three lines in diameter. All the lymphatics of the pelvic and lumbar regions presented the same alteration in a still more remarkable degree. None of them were less than two, many of them from three to four lines, and the thoracic duct was from six to eight lines, in diameter. As no obstacle was found in the course or at the termination of the thoracic duct to account for the dilatation of the lymphatics in this singular case, and as these vessels had undergone no other perceptible change, I am disposed to consider it as an example of *malformation* of these vessels."

On the Analysis of the Blood and Urine in Health and Disease. With Directions for the Analysis of Urinary Calculi. By G. O. REES. London, Longman, 1836. 8vo, pp. 147.

THE profession desire, says Mr. Rees, to know more of animal chemistry. Medical students already pursue the study vigorously, and their elders become unwilling to lack the scientific knowledge possessed by the apprentices. He therefore here presents them with what is described as "a concise view of those plans of analysis of the blood and urine, which may be performed" easily, cheaply, and usefully. The design is good, and it is gratifying to find the execution in the hands of a practical man, one who is not a mere book-maker. When the former, in addition to his experience, possesses a good understanding of words, and such clearness of head as will enable him to write comprehensibly, there is reason to

congratulate the studious public on his literary labours. But few authors esteem the latter qualities. Consequently six volumes in every seven that come from the press, present us with such unpardonable outrages upon the English language, that their chief purpose is wholly lost and defeated. It gave us pleasure, therefore, to meet with a book whose author seemed alive to this error:—

"I have avoided as much as was possible those formal methods of description which have frequently disheartened the beginner from even reading a process, much more putting it to practice. If any such feeling be entertained by my readers, let me assure them that it is the reading, and reading only, that perplexes them; and that when once they have commenced the practice of the process, all confusion will pass away, and the facts become clearly and firmly impressed upon their minds."—*Preface*, p. iv.

We cannot altogether approve the "reading," that is to say, the writing, of this passage, and we have also, elsewhere, here and there, some rather perplexing, and some rather superfluous passages; for instance, in speaking of *filtration*, Mr. Rees advises that

"When pouring from any vessel into a filter, the lip of such vessel should be kept perfectly dry, otherwise the fluid is liable, after passing the lip, to run backwards to the bottom of the vessel, and thus be lost."

And his instructions for *weighing* are rather excessively described in the following passage, which does not end even with the lines which we have placed in italics:—

"Accuracy is greatly ensured by the habit of weighing by counterpoise, which is by balancing the substance to be weighed with dry powdered sand (or any other convenient powder); and then, on removing this substance, whose weight is to be ascertained, and counterpoising the sand in the balance with the weights, the most accurate result is obtained; for the number of grains, or parts of a grain required, must be identical in weight with the substance removed, before they can produce the same effect, of precisely balancing the sand."

Were it not very desirable to seize opportunities of urging our medical writers to pay more attention to the manner, as well as the matter of their books, we should not have delayed our praise of this volume to advert to a point which Mr. Rees himself in his preface presented to our attention. We could fill a *LANCET* any day with the exposition of the difference between what some authors actually say, and what they

really mean in any one chapter of their works.

Our remarks on the volume generally need not belong. We say as much as, and no more than, it deserves, in stating that it is an excellent book of instruction in analyses of the blood and the urine, in health and disease, quantitative and qualitative, with simple excess or decrease of their natural constituents, and with the addition, when present, of foreign substances. Personally familiar with all the processes, the author is not mere copyist, and he has repeated the researches of others where his own experience was too limited to be drawn upon for his descriptions.

His remarks as a medical practitioner are not numerous. The volume is, very properly, almost entirely confined to its expressed object. We extract, however, a few remarks by way of specimen, and with them close our notice.

Extraneous Principles in Urine.—"The urine frequently presents the various odours and colours of vegetable matters which are taken into the stomach; and the examiner must be on his guard against being deceived by such appearances. Thus, I have known a patient on the point of being treated for hæmaturia, when the urine (by a mere chance) falling under my observation, I discovered the red coloration to proceed from the presence of a vegetable matter. On inquiry, the patient stated that he had been eating a salad, of which beet-root was an ingredient, during the last eight or ten days of his medical friend's visits."

"*Mercury* has been said to exist in the urine of those who use frictions with mercurial ointments. This observation was made by Cantu, who obtained metallic globules from a sediment. I had occasion to examine the urine of a person who was salivated from large doses of calomel, but could not discover any trace of mercury in it.

"*Iodine* always exists in the urine of those who take it internally. I have detected it in the urine of an individual who had taken only one grain of the remedy, and that in three separate doses of one-third of a grain each."

Diabetes.—"The great difficulty to be overcome in this examination is that of determining the proportion of urea; for the sugar with which it is admixed completely prevents the crystallization, on the addition of nitric acid. There seems little doubt that many specimens of diabetic urine have been stated to contain no urea, when that principle has been present in

considerable quantity. Mr. Kussner made some experiments on this subject, from which he concludes that urea is voided by diabetic patients in the same quantity per diem as by healthy individuals. His method of detection was by plunging a mixture of the fluid with nitric acid into a freezing mixture, formed with ice and common salt; at this temperature a crystallization of nitrate of urea occurred."

Silica in Calculi.—"This substance was twice detected by Vauquelin and Fourcroy during their laborious researches into the nature and composition of urinary concretions. Vennables also reports the case of a woman who passed a calculus containing silica. It seems highly probable that this substance may exist in small proportion in most calculi; nor are we to be surprised at its being overlooked by those who examine the concretions; for, to do justice to such an investigation, it would be necessary to sacrifice the greater portion of most calculi, which is seldom permitted to the chemist, since such minute investigation has rarely been the desideratum of those who subject their specimens to his operations."

GERMAN JOURNALS.

Rust's Magazin für die Gesamte Heilkunde.
Vol. 45, Nos. 1, II., 111.

WE resume our analysis of the German Journals. The last three numbers of Rust's Magazine contain the following communications, some of which we have already noticed:—

1. Report of the Medical Practice in the *Hopital de la Charité*, Berlin, from 1833 to 1834. By Dr. BARTELS.

2. Observations in Surgery and Ophthalmology. By Dr. BUCK.

3. Remarks on an Epidemic of Dysentery at Cottbus in the year 1834. By Dr. MALIN.

4. Fracture of the Skull, with Medullary Cancer in the Cavity of the Cranium. By Professor WUTZER.

5. Observation of a Case of Caesarean Operation. By Dr. KRANEFUSS. (Analyzed in THE LANCET of Jan. 30th, page 700.)

6. On the Difference between Congestion and Inflammation. By Professor NAUMANN, of Bonn.

7. On Secondary Abscess. By Dr. NASSE.

8. Some Remarks on the Gout. By Professor J. WENDT.

STATISTICS OF "LA CHARITE," BERLIN.

No. 1 is a lengthened report of the most interesting cases &c. that present them-

selves at the medical clinique of *La Charité*, Berlin, during the year 1833-34. We can only afford space for a notice of the statistical summary.

During the summer session 105 patients were treated; of these were

Cured, 57; incurable, 7; removed to other establishments, 12; died, 12; remained under treatment, 17,

During the winter session 141 patients were treated; of these were

Cured, 81; improved, 7; transferred, 11; died, 23; remained, 19.

Thus of 246 patients treated we have,—128 cured and 35 deaths; while the remainder were either imperfectly cured or incurable.

The paper No. 2, entitled "Observations in Surgery and Ophthalmology," by Dr. BUCK, contains a division entitled

POLYPI OF THE UTERUS.

The three following cases of uterine polypi present each several points of interest. In the first, we find an example of extirpation of the tumour while contained in the cavity of the uterus, an operation which most writers have considered as impracticable, though the present case shows that it may be had recourse to with full success.

CASE 1.—A poor woman, forty-six years of age, generally enjoying good health, the mother of six children, was seized at the age of forty-four, with a severe hemorrhage from the uterus, which continued for eight days, and was attributed to fatigue and exposure to cold. Her menstrual periods had always been natural, and the discharge did not return again for twelve months; during this time, however, she experienced constant weight in the hypogastrium, with acute stitches in the sides, pain in the pelvis, and difficulty of making water. After the lapse of a year the hemorrhage returned, with aggravation of the symptoms, and was repeated at short intervals. The author being called on to see the patient in January 1834, found that the loss of blood had been replaced by a fluor albus. The woman was now very much reduced; her general appearance was cachectic, and she was unable to leave the bed; she had severe pain about the iliac region, which was aggravated on pressure, although nothing could be discovered in the shape of tumour, induration, &c.; the pulse was small and weak; cough frequent; she vomited occasionally, and was unable to bear anything but light food; she complained from time to time of weak labour-pains. On examination the uterus was found occupying its normal situation; the inferior segment not developed, but soft and thin; the lips of the os tincæ were completely

effaced, and the uterine orifice itself was dilated to the size of a sixpence (*zweygroschenstucks*), so as to admit the index-finger. On passing the finger into the cavity of the uterus it was easy to feel and determine the existence of a polypus of the size of a large pear, which was implanted into the fundus and did not descend quite so far down as the os tincæ. It was impossible to reach the peduncle with the finger, but the inferior portion of the tumour, which was quite insensible, could be circumscribed. The author's first care was to improve the patient's health, and, if possible, promote the descent of the tumour into the vagina. For this latter purpose he administered the *secale cornutum*, but without effect. The general symptoms now became more pressing; copious discharge of foul mucus: severe cough and pain in the chest; watery diarrhœa; hectic fever &c. set in. An operation became indispensable, and was performed in the following manner.

The patient being placed in a demi-recumbent posture on the edge of her bed, the operator, who employed the instrument of Jorg, commenced by introducing the extremities of the tubes, oiled, and furnished with their threads, along the left index-finger, as high up as possible along the root of the polypus. One branch of the instrument being fixed, the operator, turning the concave surface of the second branch towards the polypus, succeeded in embracing the neck with his ligature, and fixing the two branches together. In order to avoid injuring the uterus the operator took the precaution of exercising the pressure required for manœuvring his instrument, rather on the polypus than against the sides of the uterus. However, the latter organ did not experience any pain or contraction, although frequently stimulated by the branches of the instrument. The ligature was gradually tightened for eight days, at the end of which period it came away, but, on examining, it appeared that only one-half the tumour had been destroyed. A second ligature was now applied, but with much more difficulty than the first, because the body of the polypus was reduced in size, while its peduncle seemed very thick and fibrous.

The effects of the copious foul discharge were counteracted by frequent injection of an antiseptic lotion. The inquiet state of the patient induced Dr. Buck to remove the ligature in a few days; he could now discover nothing but some fibrinous concretions, that were soon discharged with the pus. In fourteen days the polypus seemed completely destroyed, the uterus had recovered its normal form; the general symptoms rapidly diminished, and at the expiration of two months the female perfectly recovered her health, and the menses again became regular.

CASE 5.—A well-constituted lady, forty-six years of age, commenced to menstruate regularly every four weeks at the age of eight years. This state continued for six months, and was not accompanied by any other sign of precocious development. After having continued for six months, the catamenia disappeared until the age of fourteen, and continued regularly until the patient's sixteenth year, when they were suddenly arrested by a fright. Four weeks afterwards, on the very day that the menses were accustomed to appear, the patient was attacked with violent inflammation of the throat (*angina tonsillaris*), which threatened suffocation. This inflammation was subdued by proper means, and the catamenia reappeared in four weeks, but were, on several occasions, in the course of the year, supplied by a return of the angina: the consequence of this repeated inflammation was an induration, with tumefaction of the right amygdala, which Professor Fischer removed with the ligature. The patient was now nineteen years of age. During the two following years the catamenia were very irregular, but the patient remained free from inflammation of the throat, and the functions of the uterus were restored by invigorating remedies, sea-bathing, &c.

Madame S. was married in her twenty-third year, and gave birth to five children within eleven years; each labour was difficult, but terminated naturally; severe flooding always appeared within the first twelve hours after delivery, and reduced the patient to a state of great debility. During her pregnancy, and while suckling her four first children, Madame S. was free from inflammation of the throat, but six weeks after her last delivery this affection returned on three several occasions. After a lapse of two years, the patient, now thirty-six years of age, was seized with severe loss of blood from the uterus, with pain in the hypogastric region, and a dragging sensation in the loins. From this period the hemorrhage was repeated, at first every six or four months, and, latterly, every three or four weeks, and was always preceded by some mental contrariety. She now complained of increased debility; pain in the lower part of the abdomen; difficulty of making water; the bowels were irregular, and, from time to time, a pricking pain was felt in the mamma. The inflammation of the throat did not reappear.

In this state the patient continued for several years to lose a large quantity of blood. In the month of October, 1855, during an effort which the patient made, a large body was suddenly projected beyond the external labia, with a violent flooding. A *sage femme* mistook the tumour for a prolapsed uterus. The patient was now confined to bed, and suffered extremely from

repeated the disease for several years. Several physicians mistook the disease for inversion of the uterus, and after vain attempts at replacing the organ, recommended astringent and tonic remedies.

These means were of no benefit, and in the year 1830, Dr. Buck was called on to visit the patient, whom he found excessively reduced by the repeated floodings; her body was covered with a cold clammy sweat; she complained much of giddiness in the head, and a periodical dragging feel in the right thigh; the face was pale; the eye dull; the pulse small, frequent, and intermitting; the nights were disturbed; the bowels very costive; the excretion of urine frequent and painful; the blood discharged was sometimes dark and clotted, sometimes thin and watery. On external examination the abdomen seemed soft, even a hand's breadth above the right ilium, where the patient complained of a constant dragging pain not increased by pressure. There was no trace of depression or curvature above the pubic symphysis; the vagina was occupied by a round body as large as a closed fist, quite insensible to pressure, and of a firm smooth surface. The tumour did not yield under compressions, but was compact and dense. The peduncle, two inches in thickness, was not completely surrounded by the os uteri. Where the extremity of the peduncle joined the vagina, there could be felt above and somewhat to the left side, a semilunar, slightly elevated and tunched edge, with a depression, but everywhere else a flat retiring angle. It was impossible to introduce the finger, or a probe, into the depression. The author considered the body to be a polypus, which was attached to the neck, and by its pressure had closed up the os uteri.

Although this body had been considered by most of the patient's medical attendants as complete inversion, with prolapsus, of the uterus, while the state of the os tunc rendered the diagnosis still more difficult, yet two principal reasons induced the author to adopt the idea of a polypus: first, its insensibility to pressure with the nail, a circumstance never observed in the uterus; and, secondly, the manner in which the tumour made its appearance externally, for complete eversion of the uterus is inconceivable, except immediately after delivery; and the patient's last child was twelve years old, and the symptoms did not commence until three years after her last labour.

The removal of the foreign body was evidently the only remedy from which any benefit could be obtained. The general health of the patient was first improved by attending to complete rest of mind and body; she took internally an infusio summit. mil-lefolii and valer., with mineral acids, bark, and iron. Opium was given in the evenings, and the bowels regulated by laxatives;

the local treatment consisted in washing the parts with cold water. By these means a repetition of the flooding was prevented, and for six weeks the patient was attacked only twice, while the general health improved in proportion.

A ligature of silver wire was passed round the tumour, about an inch from the extremity of the peduncle; in about twelve days the tumour began to soften and come away in a sanguineous, purulent, foul discharge: on examining the vagina, the vaginal portion of the uterus, which in size and properties resembled an organ a few days after delivery, was found in a normal state, filling the cavity of the sacrum; the os uteri had an irregular angular form; some fragments of the polypus adhered to the anterior lip, and were partially removed by the finger; the rest came away with the pus.

Six weeks after the operation, the patient, who for ten years had remained free from any inflammation of the throat, was again attacked with this affection in a very severe degree; however, the symptoms were removed by a treatment with mercury and camphor. During the six months which followed the operation, the patient had no flooding whatever; the catamenia then appeared, at first somewhat abundant, but natural afterwards. At the present day, five years after the operation, Madame S. enjoys perfect health.

CASE 3.—A female, originally of healthy constitution, forty-four years of age, whose catamenia always were regular, though somewhat profuse, gave birth, within a period of thirteen years, to three healthy children, of whom the youngest is six years old. Her husband, a powerful man, forty years of age, was seized about two years previously to the present period, with an erotic monomania, under the influence of which he had connection with his wife more than four times a day for the space of a fortnight. Immediately after this the menstrual discharge became more profuse, the intervals more short, and since April, 1832, a constant discharge took place from the vagina, of blood, or whitish mucus. If we except a more frequent desire to pass water, the patient suffered under no local pain beyond an uneasiness about the pelvis; the appetite, bowels, sleep, &c., were regular. The flooding however continued, and Dr. Buck saw the patient in the summer of 1833; she was now very much reduced, the countenance pale, and the temper very irritable. The loss of blood was moderated by proper regimen, alum, bark, and the mineral acids. On examining the vagina, the inferior segment of the uterus was found swollen, and hard; the os tunc somewhat dilated; these symptoms, joined to the obytinate nature of the disease, in-

duced the author to diagnosticate a polypus still enclosed in the body of the uterus. One evening, the flooding, which had been suspended for ten days, having returned with increased violence, the patient began to experience severe pains, similar to those of labour, which continued with brief intervals for about an hour and a half; after the expiration of this time, the author recognised by the touch the presence of a large, hard, pyriform, perfectly insensible polypus filling the vagina.

The operation was performed in this case as in the two former; the ligature came away on the sixth day, and the remnant of the tumour was easily extracted from the vagina. The polypus had lost nearly half of its volume, presented a yellow-white surface, a fleshy consistence, and was lined with a smooth mucous envelope. All discharge now ceased, and the patient recovered her former health under the use of strengthening remedies, bark, colombo root. *tinct. ferri acetici aeth.*, &c.

The above cases of uterine polypus are calculated to give rise to some reflections of a practical nature which are not without interest. Whenever a female is subject to any discharge from the vagina, whether of blood, or mucus, or not, it should be an invariable rule with the physician immediately to examine the state of the uterus and internal organs of generation. In the first of the cases now before us, the true nature of the disease had been mistaken for a length of time, and the patient's life brought into great hazard. In the third, the ordinary symptoms of uterine polypus were altogether absent; however, the state of the os uteri, and the obstinate nature of the discharge from the vagina, led to the idea of polypus, and the progress of the disease soon removed all doubts upon the subject. The process by which a polypus makes its way into the vagina is not a passive one; the tumour, distending and stimulating the body of the uterus, produces an action similar to that of labour; the neck of the uterus is effaced, the os tincæ softens and becomes dilatable, labour pains more or less severe set in, and the foreign body is expelled into the vagina with many of the symptoms of true labour. This is well illustrated in the third case, where the period of time during which the tumour was being expelled, lasted for an hour and a half. In many cases, however, the passage of the polypus through the os uteri is not accompanied by any very remarkable phenomena.

The possibility of placing a ligature round

a polypus, and its removal by the os uteri, and thus expelling the foreign body, whenever the os uteri is moderately dilated, is fully established by the first case we have reported; and the operation is indicated whenever the uterus is not sufficiently irritable to expel the tumour into the vagina, while the life of the patient is endangered by the constant loss of blood. This passive condition of the uterus is even favourable to the success of the operation, from which we should not be deterred by any idea of its difficulty. The presence of a polypus in the cavity of the uterus may be concluded when, under the circumstances alluded to, we feel an insensible moveable body through the dilated os uteri. As long as the polypus is closely embraced by the uterus, and the os tincæ contracted, the symptoms are generally of a mild nature, and we are not called on to interfere in a case where all operation would be impossible.

Experience also proves that we are not to adhere too strictly to the opinion of some writers who reject the operation whenever the general health of the patient is very much deteriorated: when hectic fever, with anasarca, diarrhoea, vomiting, &c., have existed for any time. The first and second cases prove that under these unfavourable circumstances the removal of the polypus, so far from hastening the patient's death, may be speedily followed by rapid recovery. Writers generally describe polypus of the fundus uteri, as being attended with severe flooding, while those which arise from the neck or os tincæ produce little or no loss of blood, but rather an abundant fluor albus. This rule admits of several exceptions. Thus in the two first cases we observe exactly the contrary. In the first the polypus was attached to the fundus uteri, the organ itself was relaxed, and the os tincæ dilated, yet the hemorrhage was moderate, and during the last six weeks nothing came away except a quantity of mucous fluid; while, in the second case, where the tumour was attached either to the cervix uteri or one of the lips of the os tincæ, the floodings continued with great severity for ten years, yet the tumour was not of a spongy nature, but compact, and enclosed in a smooth membrane. This circumstance gave no certain indication of the point into which the polypus was inserted, which we can never determine without repeated and careful examination.

VAGINAL CYSTOCELE.

The following is a curious case of a very rare disease:—

CASE.—A woman, 54 years of age, apparently of good constitution, gave birth to her second and last child twelve years back. The labour was difficult, and the midwife, according to her own account, obliged to move the placenta. The patient, however, passed through the first few months without any accident, but in the following years she frequently experienced a sensation as if vacuum were suddenly formed in the lower part of the abdomen by the descent of something which caused a pressure in the vagina, joined to pain. These sensations continued for some years, when one day she felt a round firm body in the vagina, which became more palpable whenever she made any odily exertion. After the lapse of a few years this body protruded externally beyond the orifice of the vagina, and was at first easily replaced by the patient. At length, however, the tumour became more enlarged, and she found it impossible to return it within the labia externa. There was no difficulty of making water; in this state she continued to suffer for three months, until medical aid became indispensable.

The author, Dr. Buck (whose "Observations" we are still analyzing), on examining the organs of generation found a hard body as large as a seven-months' child's head projecting beyond the external labia. The tumour was everywhere dense, and covered early all over with cauliflower excrescences which produced a foul and ichorous secretion. The lower third was free from excrescence, of a deep-red colour, and closely resembled in appearance the vaginal segment of the uterus. A probe was introduced, half an inch deep, into a transverse slit, which was considered as the os tincæ. On passing the finger round the tumour, which very easily bled and seemed closely united above the labia, it was impossible to introduce the finger further than a blind angle that everywhere circumscribed the fungous mass. The vagina, everted and prolapsed, seemed to embrace the body of the tumour, and had contracted so close an union with the membrane of the labia as to form nearly a straight line to the perineum. On examination by the rectum no trace of the uterus could be found, but the finger penetrated above into a thick sac, apparently the everted vagina. The author attempted in vain to introduce the catheter in the ordinary manner, as the orifice of the urethra was excessively painful and closed by large vegetations; besides, no urine was secreted in normal quantity, and the tumour did not undergo any change of volume on being excreted, nor was any desire to make water produced by pressing upon the tumour. The disease was diag-

nosed as a complete prolapsus of the uterus, which, in consequence of the contact with air, urine, &c., had taken on cancerous ulceration.

Several surgeons and accoucheurs by whom the patient was examined being of the same opinion, it was determined to operate the removal of the tumour by carefully dissecting away the vagina from its connections with it. The intestinal canal being emptied, and the patient placed as in the operation for lithotomy, several assistants endeavoured to introduce the catheter, without success, until Dr. H. having by chance turned the instrument in a nearly perpendicular direction, passed it into the bladder, a thing which certainly would not have taken place had that viscus occupied its natural position.

This circumstance threw some doubt for the first time on the nature of the accident, but as the end of the catheter could not be felt externally, while it was discovered at the posterior wall of the tumour by introducing the finger into the rectum, the displacement of the bladder was considered as having followed that of the uterus, and the operation was continued. An incision of several inches was made into the thickened wall of the vagina, underneath the tumour, and the latter dissected away with the bistoury, constantly turned towards the swelling, lest the rectum might be injured. However, instead of arriving at the substance of the uterus, as was expected from the direction, the operator fell upon true muscular fibres, where the catheter could now be felt, as a firm envelope, at least one quarter of an inch thick, had been removed from the tumour. These two circumstances rendered it evident that the tumour was in great part, at least, composed of the bladder, without its being clear in what manner this latter was connected with the uterus. Another incision was now made, superiorly, near the orifice of the urethra, and continued down

to the first one; and the external coat of hard fungous masses was dissected away without the bladder being injured. The catheter could now distinctly be felt at all points of the parietes of the tumour, which had lost half of its volume, and being freed from excrescences presented a smooth surface; it was partially replaced after a few gentle attempts, and the patient put in bed.

She passed the first days pretty well; the pain of the wound was slight; the appetite moderately good; the abdomen free from pain and not tumid. These favourable symptoms continued for more than three weeks after the operation, when the appetite began to give way. The patient became feverish; the edges of the wound dry and red. A colliquative diarrhoea now set in, and carried off the patient on the sixth week.

On examining the body after death, the tumour which had been mistaken for the uterus was found to be the bladder, the inferior and posterior walls of which, clothed by the vagina, had gradually descended and projected beyond the great labia. The inferior part of the tumour, which still resembled the inferior segment of the uterus, presented a smooth surface, whose tissue was compact and of a cartilaginous consistence. It was necessary to make an incision of one inch and a half, from below upwards, to arrive at the bladder at this point.

The transverse fissure, which was considered as the os tincæ, and contributed more than any other circumstance to the error of diagnosis, was formed by a peculiar fold of the vaginal mucous membrane, for which it is difficult to account. The extraordinary development which the vagina had attained in this case is worthy of notice; it was only the superior part, which in a normal position lies close to the bladder, that could have formed the exterior covering of the tumour. It is also evident that the bladder had not descended through a rupture in the parietes of the vagina, since the latter membrane surrounded the tumour on all sides. The portion of the bladder which was displaced, was degenerated and thickened; the fundus covered by the peritoneal tunic, still lay in the cavity of the pelvis, and was nearly in a healthy state. The uterus was also normal, but situated a little higher than it should have been in the hollow of the sacrum. If we reflect on the external appearance of this tumour, and its great resemblance to the inferior segment of the uterus, the persistence of volume, even after the urine was drawn off, and the absence of all symptoms that usually indicate an injury of the bladder, the difficulty of forming a correct diagnosis will be easily conceived. The treatment indicated after the error was recognised, consisted simply in removing the cancerous portion of the vagina, and returning, as far as was possible, the tumour to its natural position.

THE LANCET.

London, Saturday, March 19, 1836.

WHAT is to be done with the tax upon quackery? This question is now heard in every intelligent medical community. The answers to it are various, but all the experienced practitioners seem to agree in the opinion, that if an ANTI-MEDICAL-QUACKERY SOCIETY could be established, and could be brought into general action throughout the country, the downfall of empiricism would be rendered more certain by the operations of that society than by the influence of an Act of the legislature. If such a society could be established, what in the name of common sense is to prevent its establishment, but the apathy and indifference of the profession to their own respectability and interests, and to the health and security of the community. Behold what the KING OF THE QUACKS has done by his complete organization. He has a focus of action,—a *den*, where all his imps of mischief assemble, and receive their orders for the distribution of his universal poison. The organization of *his* system is complete, and it branches out into the whole of the provincial press of the country. On examining the files at the newspaper agents in London, we find that nearly every country paper contains columns of advertisements, all puffing the wondrous efficacy of the "Universal Pills." These advertisements are also all dignified with "testimonials" in favour of the Quack and his system, from *certificated* members of the medical profession. All these things are seen. They are placed in bold relief before us, and the evil consequences are manifest in the increasing business of the undertaker; the public continue to be deluded; the poison is still swallowed by *hushes*; the science of medicine is degraded and insulted; and yet there are "members of the profession," even with hoary locks, who coolly

end lethargically. "What is to be done?" and then significantly intimate that "something might be done, if an anti-quackery society could be established." Observe. The quack wields but *one* instrument in accomplishing his object. That instrument is *the press*, which vomits forth, with horrible and destructive rapidity, advertisements, tracts, and even numbers of a periodical, in support of his nefarious projects. All his means, all his appliances, being concentrated in the powers of *one* instrument, that instrument is then brought to bear upon *one* material, namely, the ignorance, or, in other words, the *credulity* of the public.

What considerations, then, can deter the members of an honourable profession from boldly grappling with the monster FALSEHOOD, in the very scene of its birth and activity? The public mind should be disabused, and there are no means so ready, or so efficient, for the accomplishment of this object, as that of resorting to the all-powerful aid of the press, which, by polluted hands, has been rendered the source of so much national mischief. "If an ANTI-MEDICAL-QUACKERY SOCIETY could be established,—why then, why then?"—Oh, how sickening are these doubts and difficulties, where nothing but energy and common sense are required! If the Society were but *in existence*, what *then* would be the conduct of the quackists? Why they would instantly become subscribers, and obtain from the secretary a supply of tracts containing descriptive accounts of the last moments of the persons who had fallen victims to the use of "universal vegetable medicines," and accounts of the thousands of deaths which have been caused by the use of secret or quack medicines, in general. The best evidence of what might be the results of a combined activity on the part of the members of the profession, thus directed to the diffusion of useful knowledge among the people, is already found in the fact, that in those districts where it is actually known to the in-

habitants, that death has ensued from taking the "vegetable medicines," there the sale of the horrid stuff has been almost abolished.

"Oh, but," it will be remarked, "the increasing intelligence of the public will, of itself, prove a sufficient corrective for the evil of quackery."

The persons who speak thus are themselves but sorry examples of the soundness of their own opinions. If man had been created on the 1st of last January, and if we had positive proof that he did not commence thinking in a rational manner until Monday last, at about nine o'clock in the morning, then, indeed, a *hope* might be entertained that the *rapid* growth of intelligence would lead to the substitution of a *sound belief* for a *credulous faith*. In short, REASON would eject IGNORANCE from its throne. How, we would ask, is the growth of intelligence to be promoted, unless the young plant be nursed and cultivated by wise and experienced hands? If credulity with respect to quackery existed only amongst the uneducated, or in the ranks of the poorer classes of the community, the apathetic might find some justification for their supineness; but when it is proved to demonstration, by what happened in the case of JOHN LONG, as well as in that of MORISON, and the advertising disciples of HAHNEMANN, that the *aristocracy* of the land are the victims of misbelief with respect to the philosophic principles of the science of medicine, and are credulous, beyond conception, in all matters which have reference to the professions of quacks and the curative powers of their nostrums; we say that circumstances have arisen amongst us which demand the most energetic and powerful combination on the part of the profession, in order to exterminate an evil which has been, and still is, productive of so many fatal consequences to the community.

In considering this subject one thing must always be borne in mind, namely, that

the means which could be employed for the publication and the dissemination of truth, are as much or even more at the disposal of the members of the profession, than they are at the disposal of a quack, whatever may be the wealth which he has contrived to extort from the pockets of the people. Here, then, we have at least ten thousand members of an honourable profession, men of science, moving in the highest ranks of society, and yet, can it be believed, they allow TRUTH to experience the worst of a contest in an honourable struggle with FALSEHOOD. The exhibition is a scandal to the profession; and really, if there be any *esprit du corps* in the medical community, if there exist in the minds of medical practitioners a high-minded feeling regarding what is due to the profession to which they belong, and to the health and welfare of the nation, they will rise *en masse* against the miscreants who dare to wrest from them their privileges, and who are making the press a wide-spreading source of pollution to the public mind. Some there are who may look forward with confidence to what may be done by the House of Commons for the suppression of quackery; but the day, we fear, is distant, when that House will act as it ought in such an emergency. Unfortunately the members of that assembly are not proof against ignorance in medical matters, and there are honourable gentlemen in that House who believe that their own valuable persons have been preserved for the benefit of the existing generation, and their talents for the advantage of posterity, by the careful and continual use of "Huxham's Tincture of Bark!" But what just ground can the members of the medical profession have for believing that any other body of men will exert themselves effectually for the suppression of medical quackery, while they themselves remain inactive? Who are the best judges in this matter? Assuredly medical men. Their opinions on the subject are formed after extensive research

and laborious study. Their convictions are made up of rational and just convictions, and yet, when the result of their conviction is only apparent in *apathy*,—when all the energies of the intellect are required to avert a frightful evil,—a conjecture is raised by the supine parties, that other persons who have no conviction,—who have only an absurd faith for steadying their principles, will endeavour to convert what they do not regard as a calamity into a *public blessing*! The supposition is really monstrous, and is only another indication of that unsound state of understanding which, at the present period, is but too prevalent among all classes of society. We repeat, that it is in the power of the members of the profession, by a slight degree of organization amongst their members, to annihilate the pretensions of quacks, and their odious slaying nostrums. In showing how that organization could be effected, we, at any rate, thus far, have discharged our duty, and if medical gentlemen will but co-operate in the manner we have explained, they shall not stand in need of the aid of THE LANCET towards giving efficiency and universality to their exertions.

ROYAL DUBLIN SOCIETY.

THE *Royal Dublin Society* has at length crossed the "Rubicon." By a vote of its members at a meeting recently held in Dublin, it has announced its determination to set LORD MULGRAVE, and the voice of the Irish people, at defiance. The wise and reasonable propositions submitted to the Society by the under-secretary for Ireland, MR. DRUMMOND, were indignantly rejected at that meeting by a large majority. It was scarcely to be expected that there would be even a small minority to stand between the infuriated orange maniacs of the Society and their own destruction. What will be the result of the step thus boldly taken by them it is not difficult to conjecture. Let us consider that the contest is between the most impotent coterie of the fallen orange faction in Ireland, and the most popular and gifted viceroy that ever presided over the

in government. We never, indeed, doubt-
 the suicidal capabilities of the Dublin in-
 stitution. Its composition and history were
 not too well calculated to prepare those who
 are best acquainted with both, for that
 rash termination of its political existence
 to which its late measures must hasten it.
 Made up principally of the *elite* of the
 orange squirearchy of the city and the
 county parts of Ireland, they have too long
 drunk from the intoxicating cup of misrule
 and bigotry, to yield without a struggle to
 the dictates of reason and prudence. Like
 their desperate allies of the Irish corpora-
 tions, they would prefer the annihilation of
 a Society, the advantages of which they
 pretend so much to respect, to its falling
 under the management of the national mind.
 We have heard it stated, indeed, that the
 charter of the Society warrants the course
 which its possessors have pursued, and that
 in the exclusion of liberal men, only a
 legal right has been exercised. If, after
 what occurred in the case of Dr. MURRAY,
 the Charter really confers any such power,
 it could be forthwith cancelled, and one
 ruled on more rational principles should
 be substituted. The sophistry spoken and
 pressed on this topic, will, or ought to be,
 thus answered by the British Government;
 for if that Society, supported as it has been
 by grants from the national treasury, is to
 retain a sectarian or a political character,
 and to have power to exclude from its coun-
 cils and its management, all those who
 happen not to entertain the same opinions
 as its present governors, then would it be
 better if the Society were altogether sup-
 pressed, than that it should remain a centre
 of dissension, and an instrument for the
 assassination of character,—the most esti-
 mable in the country. The good which
 this Society has achieved for Ireland has,
 we perceive, been prominently urged as a
 proof of its proper administration, and as
 a reason for its future preservation. We
 neither deny that it has accomplished some
 good, nor are advocates for its demolition.
 There can be no question that the labours of
 a society of this kind, under judicious direc-
 tion, would be highly useful in the present
 state of Ireland; and we only express the
 feelings and wishes of the inhabitants when
 we assert, that they are most anxious for its
 conservation. We are at the same time
 well aware that the benefits actually con-

ferred by the institution have been grossly
 exaggerated, and purchased at much too
 great an expense. The improvements
 made in the agriculture of Ireland (the ob-
 ject for which this Society was established)
 are owing, not to the suburban husbandry of
 the "gentlemen farmers" of that body, but
 to the gradual progress of intelligence in
 this and in every other class of society in
 that country. We may venture to affirm
 that the simple introduction of the Scotch
 plough and the Scotch drag, has enriched
 more fields and reclaimed more waste
 lands in Ireland, has conferred more sub-
 stantial advantages on that country, than
 all the lectures ever delivered by WADE
 or by LITTON. We well recollect, indeed,
 the anecdote of a gentleman who informed
 us that, walking one day through a farm
 occupied by one of the Society's most scien-
 tific husbandmen in the neighbourhood of
 Dublin, he inquired of a rustic neighbour
 whom he happened to meet, what was the
 success of the owner. "Ah, Sir," was the
 reply, made with peculiar *nécessité*, "Mr. —
 is indeed an excellent farmer, and a very good
 man, but the devil a one ever saw a stack of
 corn or a rick of hay in his haggard yet!"
 Of this Ulyssean species of agriculture,
 "ploughing the sand and sowing it with
 salt," the Royal Dublin Society achieved
 quite enough to incur the contempt of every
 practical cultivator in the country. It is
 only within the last eighteen months that
 a portion of the Society's Garden has been
 appropriated to the cultivation of the best
 kinds of fruit trees, garden vegetables, and
 field crops,—an object which, though par-
 ticularly belonging to the Society, was pre-
 viously much neglected. Every visitor of
 their garden must have observed that it had
 been falling for years into a state of ruin
 and decay; and if it now wears, as it certainly
 does, a different aspect, the improvement is
 attributable rather to the taste, the intelli-
 gence, and the attention, of the present con-
 servator, than to the exertions of the So-
 ciety itself. Then, if we look to the mu-
 seum, we shall find it to be one mass of
 ignorant confusion from beginning to end,
 answering no kind of useful purpose in its
 present state, and being simply a spectacle
 for the gaze of the idle. Among the few
 in Dublin who devote themselves to the
 study of natural history, it is a general com-
 plaint that the arrangement and nomen-

clature render the specimens and preparations almost valueless. Yet the Society had for many years in pay a man who had obtained in Ireland the easy reputation of a naturalist. The evidence he has left behind him seems to prove that he was either incompetent to the duties of his office, or too much occupied with the mysteries of "Orangeism," to attend to those of nature. An attempt, we understand, is now being made by Dr. SCOUER to repair the errors and neglect of his predecessor; but much time is likely to elapse before so difficult a task can be accomplished. It is unnecessary to detail the other neglects and misapplications of the funds of the Society. Those errors are, after all, secondary to the great question, whether the Society, with its present constitution, is calculated to effect the proper objects of such an institution. No one who comprehends the state of political feeling in Ireland, or the composition of the Society, will answer this question in the affirmative. To effect its legitimate purposes, the Society should possess the confidence of the people whom it purports to instruct, or every effort to diffuse information among them, and improve their condition, will be fruitless. It was in a great measure the absence of a mutual feeling and good will between the Society and the people, which circumscribed within such narrow limits the influence and advantages of the Institution. To no purpose is the machinery of instruction exhibited, or the usual mode of communicating information adopted, while the guiding spirits of the didactic pageant are, in most instances, the judges who "charged" against the liberties of the country, the crown-lawyers who hunted down its miserable population, the proprietary who expatriated them by thousands, and the corporate burgesses who carried with them into the Institution the same exclusive principles which made them objects of detestation to their fellow-citizens out of it. The ardent and sensitive temperament of the Irish refused to receive proffered favours from such hands, and the community consequently left the junta in the solitary enjoyment of those treasures of which the Society was intended to be the steward, and not the monopolist. The people of Ireland responded to the invitations of the Society to receive improvements at its hands, as Demetrius replied to the Areo-

pagites in the days of their corruption, telling them that if they desired to reform Ireland, they should commence the reformation at home. Unsupported by public opinion the Society languished, its time and means were wasted in unprofitable and oftentimes mischievous trifling, its lecture rooms became the lounge of the idle or the fashionable, its news and committee room were converted into convenient centres for the discussion and diffusion of rancorous and anti-national politics, and the labour of its professors were turned into a jest. It is this spirit which so successfully achieves those evils which an ultra-party of bigots in the Society wish to perpetuate, and which it is the duty, as we believe it to be the inclination, of the present paternal government of Ireland, to prevent. Supported by the voice of a people anxious for improvement, and demanding but simple equality and justice, the Government are called upon to defeat the malicious attempts of this faction to convert into a mere social and political club, an institution and a property created for the most part out of the public funds, and intended for national purposes. The Society, to be of any real advantage to the country, must be liberalized, and so constituted, that the religious or political opinions of a member or of a professor should form no impediment to the admission of the one, or the appointment of the other. For the attainment of this reasonable object, the people look with deep, though comparatively silent, anxiety to the head of the Irish Government, who, in the adjudication of the question, we have no doubt, will display the same uncompromising and impartial policy which has characterized all his measures since his arrival in Ireland. We cannot conclude these remarks without advertin- to, we believe, the only defence of the Society which has appeared in print. We allude to the letters of Dr. Meyler on the subject. Had these letters been written by an avowed Tory, or a known partisan of the Society, the public would, of course, know how to appreciate them at their proper value; but coming from a writer professing liberal principles, and from his connection presumed to be sincere in his professions, they derive a mischievous importance from their duplicity, and the ignorance of those who may have read and been influenced by them. It is, however, merely sufficient

that this philosophic lover of his country, has made the pages of the "Mail" vehicle of his lucubrations, in order to free them of their misguiding tendency. Was there no other medium in Dublin through which this ardent philanthropist could make known his love of country and his convictions of the utility of the Society? Were the columns of even the "Post" too cool for the communication of his warm and benevolent feelings towards his benighted countrymen? Should he again, however, take up the pen in defence of the Society, it will we apprehend, be not necessary to do which, in the first instance, was the duty of an honest man—to inform his readers to what party he really belongs.

ERINENSIS.

Dublin, March 10, 1836.

HOSPITAL STATISTICS.—The fourth number of the first vol. of the *Medizinische Annalen* (German journal) contains a review of the medical clinique of the University of Heidelberg for the years 1832-3-4. The following statistical results may serve as a term of comparison with those of our own hospitals. The number of patients treated during the above period was 1401; the deaths were 62, giving a proportion of mortality as 1 to 22.566. The number of externe patients treated was 1681; the deaths 83, or as 1 to 20.4.

'REJUDICE VERSUS SCIENCE.—*To the Editor.*—Sir: In further explanation of the article in *THE LANCET* of March the 5th, No. 653, under the above head, it should be generally known, that three converted Jews have been appointed professors to *King's College*, London, for teaching the German, Spanish, and Hebrew languages. Neither of them has had a university education. Mr. Bernays, the professor of German, bought, since his appointment, a diploma of doctor of philosophy at Gießen, a university in the Grand Duchy of Hesse, but he never was entered there as a student. He taught first, in this country, in a Jewish establishment of Brixton.* I am, Sir, your obedient servant,

A CONSTANT READER.

The latter part of our correspondence we have omitted. We cannot interfere with the statements which it contains. With regard to the former part, we may state that the heading of this letter has been attacked by ourselves, and should have been reversed, and announced the tri-

umph of SCIENCE VERSUS PREJUDICE. To divine, however, the principle on which a catholic institution receives into its bosom converted Jews, and rejects faithful Christians, is beyond our power.

LETTER FROM MR. HENTSCH.

To the Editor.—Sir: In your last week's number you gave a report of the meetings of the governors of the Free Hospital, held at the Gray's-inn Coffee-house, respecting the dismissal from office of Mr. Tweedie and myself, which report contains (no doubt unintentionally) several inaccuracies,† one of which, concerning Mr. Tweedie and myself, I beg leave to point out to your notice. Mr. Marsden is reported to have said that "since the publication of the testimonials, several subscribers had seceded from the charity, believing that the officers were encouraging quackery, and a representation of the fact was made to Mr. Hentsch and Mr. Tweedie, and a sort of promise obtained from them that the cause of complaint should be removed, but without realization." Now, Sir, this is *incorrect*. Mr. Marsden did not say so at the meeting, nor could he, such not being the fact. Neither Mr. Tweedie nor myself ever made a "sort of promise" that the cause of complaint should be removed, it being quite out of our power to compel Mr. Franks to cease publishing them. The insertion of the above in your next will much oblige, Sir, your obedient servant,

WM. HENTSCH,

Late Apothecary to the Free Hospital.
3, Furnival's-inn, Holborn;
16th March, 1836.

† "Several" should perhaps be "one."—Ed. L.

LETTER FROM MR. TWEEDIE.—We have also received a letter from Mr. Tweedie, addressed "To the members of the medical profession," but at a very late hour in the week, and extended to a length which would render it impossible for us, from our arrangements, to give it insertion in this number of *THE LANCET*. However, we object to publishing what would, we fear (unintentionally, we are sure, on Mr. Tweedie's part), prove a very profitable advertisement of a quack medicine, even the name of which we decline again to admit into our pages. Our late report of some late proceedings at the *Gray's-inn Coffee-house* are stated, in a note to the Editor from Mr. Tweedie, to contain "two or three serious imperfections;" but these have not been specifically mentioned by him, or they should
